```

Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

`doctest.script_from_examples(s)`

Convert text with examples to a script.

Argument *s* is a string containing doctest examples. The string is converted to a Python script, where doctest examples in *s* are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```

import doctest
print(doctest.script_from_examples(r"""
    Set x and y to 1 and 2.
    >>> x, y = 1, 2

    Print their sum:
    >>> print(x+y)
    3
"""))

```

displays:

```

# Set x and y to 1 and 2.
x, y = 1, 2
#

```

```
# Print their sum:
print(x+y)
# Expected:
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

`doctest.testsource(module, name)`

Convert the doctest for an object to a script.

Argument *module* is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument *name* is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for [script\\_from\\_examples\(\)](#) above. For example, if module `a.py` contains a top-level function `f()`, then

```
import a, doctest
print(doctest.testsource(a, "a.f"))
```

prints a script version of function `f()`'s docstring, with doctests converted to code, and the rest placed in comments.

`doctest.debug(module, name, pm=False)`

Debug the doctests for an object.

The *module* and *name* arguments are the same as for function [testsource\(\)](#) above. The synthesized Python script for the named object's docstring is written to a temporary file, and then that file is run under the control of the Python debugger, [pdb](#).

A shallow copy of `module.__dict__` is used for both local and global execution context.

Optional argument *pm* controls whether post-mortem

debugging is used. If *pm* has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via `pdb.post_mortem()`, passing the traceback object from the unhandled exception. If *pm* is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate `exec()` call to `pdb.run()`.

`doctest.debug_src(src, pm=False, globs=None)`

Debug the doctests in a string.

This is like function `debug()` above, except that a string containing doctest examples is specified directly, via the *src* argument.

Optional argument *pm* has the same meaning as in function `debug()` above.

Optional argument *globs* gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

The `DebugRunner` class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially `DebugRunner`'s docstring (which is a doctest!) for more details:

`class doctest.DebugRunner(checker=None, verbose=None, optionflags=0)`

A subclass of `DocTestRunner` that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an `UnexpectedException` exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a `DocTestFailure` exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for [DocTestRunner](#) in section [Advanced API](#).

There are two exceptions that may be raised by [DebugRunner](#) instances:

*exception* `doctest.DocTestFailure(test, example, got)`

An exception raised by [DocTestRunner](#) to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.

[DocTestFailure](#) defines the following attributes:

`DocTestFailure.test`

The [DocTest](#) object that was being run when the example failed.

`DocTestFailure.example`

The [Example](#) that failed.

`DocTestFailure.got`

The example's actual output.

*exception* `doctest.UnexpectedException(test, example, exc_info)`

An exception raised by [DocTestRunner](#) to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

[UnexpectedException](#) defines the following attributes:

`UnexpectedException.test`

The [DocTest](#) object that was being run when the example failed.

`UnexpectedException.example`

The **Example** that failed.

`UnexpectedException.exc_info`

A tuple containing information about the unexpected exception, as returned by `sys.exc_info()`.

## Soapbox

As mentioned in the introduction, **doctest** has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my **doctest** examples stops working after a “harmless” change.

Doctest also makes an excellent tool for regression testing, especially if you don't skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what's actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It's true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper than just that: the natural attitude

when writing a doctest-based test is that you want to explain the fine points of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It's a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using `testfile()` or `DocFileSuite()`. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

When you have placed your tests in a module, the module can itself be the test runner. When a test fails, you can arrange for your test runner to re-run only the failing doctest while you debug the problem. Here is a minimal example of such a test runner:

[illegible]

```
fail, total = doctest.testmod(optionflags=flags)
print("{} failures out of {} tests".format(fail,
```

## Footnotes

1

Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.

# unittest — Unit testing framework

**Source code:** [Lib/unittest/\\_init\\_.py](https://github.com/python/cpython/tree/3.12/Lib/unittest/_init_.py) [https://github.com/python/cpython/tree/3.12/Lib/unittest/\_init\_.py]

---

(If you are already familiar with the basic concepts of testing, you might want to skip to [the list of assert methods](#).)

The **unittest** unit testing framework was originally inspired by JUnit and has a similar flavor as major unit testing frameworks in other languages. It supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework.

To achieve this, **unittest** supports some important concepts in an object-oriented way:

## test fixture

A *test fixture* represents the preparation needed to perform one or more tests, and any associated cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

## test case

A *test case* is the individual unit of testing. It checks for a specific response to a particular set of inputs. **unittest** provides a base class, **TestCase**, which may be used to create new test cases.

## test suite

A *test suite* is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

## test runner

A *test runner* is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

Kent Beck's original paper on testing frameworks using the pattern shared by `unittest`.

**pytest** [<https://docs.pytest.org/>]

Third-party unittest framework with a lighter-weight syntax for writing tests. For example, `assert func(10) == 42`.

**The Python Testing Tools Taxonomy** [<https://wiki.python.org/moin/PythonTestingToolsTaxonomy>]

An extensive list of Python testing tools including functional testing frameworks and mock object libraries.

**Testing in Python Mailing List** [<http://lists.idyll.org/listinfo/testing-in-python>]

A special-interest-group for discussion of testing, and testing tools, in Python.

The script `Tools/unittestgui/unittestgui.py` in the Python source distribution is a GUI tool for test discovery and execution. This is intended largely for ease of use for those new to unit testing. For production environments it is recommended that tests be driven by a continuous integration system such as **Buildbot** [<https://buildbot.net/>], **Jenkins** [<https://www.jenkins.io/>], **GitHub Actions** [<https://github.com/features/actions>], or **AppVeyor** [<https://www.appveyor.com/>].

# Basic example

The `unittest` module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three string methods:

```
import unittest

class TestStringMethods(unittest.TestCase):

    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is not a string
        with self.assertRaises(TypeError):
            s.split(2)

if __name__ == '__main__':
    unittest.main()
```

A testcase is created by subclassing `unittest.TestCase`. The three individual tests are defined with methods whose names start with the letters `test`. This naming convention informs the test runner about which methods represent tests.

The crux of each test is a call to `assertEqual()` to check for an expected result; `assertTrue()` or `assertFalse()` to verify a condition; or `assertRaises()` to verify that a specific exception gets raised. These methods are used instead of the `assert` statement so the test runner can accumulate all test results and

produce a report.

The `setUp()` and `tearDown()` methods allow you to define instructions that will be executed before and after each test method. They are covered in more detail in the section [Organizing test code](#).

The final block shows a simple way to run the tests.

`unittest.main()` provides a command-line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```
...
```

```
-----  
Ran 3 tests in 0.000s
```

```
OK
```

Passing the `-v` option to your test script will instruct `unittest.main()` to enable a higher level of verbosity, and produce the following output:

```
test_isupper (__main__.TestStringMethods.test_isupper) .  
test_split (__main__.TestStringMethods.test_split) ... c  
test_upper (__main__.TestStringMethods.test_upper) ... c
```

```
-----  
Ran 3 tests in 0.001s
```

```
OK
```

The above examples show the most commonly used `unittest` features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.

*Changed in version 3.11:* The behavior of returning a value from a test method (other than the default `None` value), is now deprecated.

## Command-Line Interface

The `unittest` module can be used from the command line to run tests from modules, classes or even individual test methods:

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

Test modules can be specified by file path as well:

```
python -m unittest tests/test_something.py
```

This allows you to use the shell filename completion to specify the test module. The file specified must still be importable as a module. The path is converted to a module name by removing the `‘.py’` and converting path separators into `‘.’`. If you want to execute a test file that isn’t importable as a module you should execute the file directly instead.

You can run tests with more detail (higher verbosity) by passing in the `-v` flag:

```
python -m unittest -v test_module
```

When executed without arguments [Test Discovery](#) is started:

```
python -m unittest
```

For a list of all the command-line options:

```
python -m unittest -h
```

*Changed in version 3.2:* In earlier versions it was only possible to run individual test methods and not modules or classes.

## Command-line options

**unittest** supports these command-line options:

`-b, --buffer`

The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

#### **-c, --catch**

Control-C during the test run waits for the current test to end and then reports all the results so far. A second Control-C raises the normal `KeyboardInterrupt` exception.

See [Signal Handling](#) for the functions that provide this functionality.

#### **-f, --failfast**

Stop the test run on the first error or failure.

#### **-k**

Only run test methods and classes that match the pattern or substring. This option may be used multiple times, in which case all test cases that match any of the given patterns are included.

Patterns that contain a wildcard character (\*) are matched against the test name using `fnmatch.fnmatchcase()`; otherwise simple case-sensitive substring matching is used.

Patterns are matched against the fully qualified test method name as imported by the test loader.

For example, `-k foo` matches

```
foo_tests.SomeTest.test_something,  
bar_tests.SomeTest.test_foo, but not  
bar_tests.FooTest.test_something.
```

#### **--locals**

Show local variables in tracebacks.

#### **--durations N**

Show the N slowest test cases (N=0 for all).

*New in version 3.2:* The command-line options `-b`, `-c` and `-f` were added.

*New in version 3.5:* The command-line option `--locals`.

*New in version 3.7:* The command-line option `-k`.

*New in version 3.12:* The command-line option `--durations`.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.

## Test Discovery

*New in version 3.2.*

Unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be [modules](#) or [packages](#) importable from the top-level directory of the project (this means that their filenames must be valid [identifiers](#)).

Test discovery is implemented in `TestLoader.discover()`, but can also be used from the command line. The basic command-line usage is:

```
cd project_directory
python -m unittest discover
```

### Note

As a shortcut, `python -m unittest` is the equivalent of `python -m unittest discover`. If you want to pass arguments to test discovery the `discover` sub-command must be used explicitly.

The `discover` sub-command has the following options:

`-v`, `--verbose`

## Verbose output

**-s, --start-directory directory**

Directory to start discovery ( . default)

**-p, --pattern pattern**

Pattern to match test files (test\*.py default)

**-t, --top-level-directory directory**

Top level directory of project (defaults to start directory)

The **-s**, **-p**, and **-t** options can be passed in as positional arguments in that order. The following two command lines are equivalent:

```
python -m unittest discover -s project_directory -p "*_test.py"
python -m unittest discover project_directory "*_test.py"
```

As well as being a path it is possible to pass a package name, for example `myproject.subpackage.test`, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

## Caution

Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example `foo/bar/baz.py` will be imported as `foo.bar.baz`.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import *could* happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the [load\\_tests protocol](#).

*Changed in version 3.4:* Test discovery supports [namespace packages](#) for the start directory. Note that you need to specify the top level directory too (e.g. `python -m unittest discover -s root/namespace -t root`).

*Changed in version 3.11:* Python 3.11 dropped the [namespace packages](#) support. It has been broken since Python 3.7. Start directory and subdirectories containing tests must be regular package that have `__init__.py` file.

Directories containing start directory still can be a namespace package. In this case, you need to specify start directory as dotted package name, and target directory explicitly. For example:

```
# proj/ <-- current directory
#   namespace/
#     mypkg/
#       __init__.py
#       test_mypkg.py
```

```
python -m unittest discover -s namespace.mypkg -t .
```

## Organizing test code

The basic building blocks of unit testing are *test cases* — single scenarios that must be set up and checked for correctness. In [unittest](#), test cases are represented by [unittest.TestCase](#) instances. To make your own test cases you must write subclasses of [TestCase](#) or use [FunctionTestCase](#).

The testing code of a [TestCase](#) instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest [TestCase](#) subclass will simply implement a test method (i.e. a method whose name starts with `test`) in order to perform specific testing code:

```
import unittest
```

```
class DefaultWidgetSizeTestCase(unittest.TestCase):  
    def test_default_widget_size(self):  
        widget = Widget('The widget')  
        self.assertEqual(widget.size(), (50, 50))
```

Note that in order to test something, we use one of the **assert\*()** methods provided by the **TestCase** base class. If the test fails, an exception will be raised with an explanatory message, and **unittest** will identify the test case as a *failure*. Any other exceptions will be treated as *errors*.

Tests can be numerous, and their set-up can be repetitive. Luckily, we can factor out set-up code by implementing a method called **setUp()**, which the testing framework will automatically call for every single test we run:

```
import unittest
```

```
class WidgetTestCase(unittest.TestCase):  
    def setUp(self):  
        self.widget = Widget('The widget')  
  
    def test_default_widget_size(self):  
        self.assertEqual(self.widget.size(), (50,50),  
                          'incorrect default size')  
  
    def test_widget_resize(self):  
        self.widget.resize(100,150)  
        self.assertEqual(self.widget.size(), (100,150),  
                          'wrong size after resize')
```

## Note

The order in which the various tests will be run is determined by sorting the test method names with respect to the built-in ordering for strings.

If the `setUp()` method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the test method will not be executed.

Similarly, we can provide a `tearDown()` method that tidies up after the test method has been run:

```
import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
```

If `setUp()` succeeded, `tearDown()` will be run whether the test method succeeded or not.

Such a working environment for the testing code is called a *test fixture*. A new `TestCase` instance is created as a unique test fixture used to execute each individual test method. Thus `setUp()`, `tearDown()`, and `__init__()` will be called once per test.

It is recommended that you use `TestCase` implementations to group tests together according to the features they test. `unittest` provides a mechanism for this: the *test suite*, represented by `unittest`'s `TestSuite` class. In most cases, calling `unittest.main()` will do the right thing and collect all the module's test cases for you and execute them.

However, should you want to customize the building of your test suite, you can do it yourself:

```
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_widget_si
    suite.addTest(WidgetTestCase('test_widget_resize'))
    return suite
```

```
if __name__ == '__main__':  
    runner = unittest.TextTestRunner()  
    runner.run(suite())
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as `widget.py`), but there are several advantages to placing the test code in a separate module, such as `test_widget.py`:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules anyway, so why not be consistent?
- If the testing strategy changes, there is no need to change the source code.

## Re-using old test code

Some users will find that they have existing test code that they would like to run from `unittest`, without converting every old test function to a `TestCase` subclass.

For this reason, `unittest` provides a `FunctionTestCase` class. This subclass of `TestCase` can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```
def testSomething():  
    something = makeSomething()  
    assert something.name is not None  
    # ...
```

one can create an equivalent test case instance as follows, with optional set-up and tear-down methods:

```
testcase = unittest.FunctionTestCase(testSomething,  
                                     setUp=makeSomething,  
                                     tearDown=deleteSomething)
```

## Note

Even though `FunctionTestCase` can be used to quickly convert an existing test base over to a `unittest`-based system, this approach is not recommended. Taking the time to set up proper `TestCase` subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the `doctest` module. If so, `doctest` provides a `DocTestSuite` class that can automatically build `unittest.TestSuite` instances from the existing `doctest`-based tests.

# Skipping tests and expected failures

*New in version 3.1.*

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an “expected failure,” a test that is broken and will fail, but shouldn’t be counted as a failure on a `TestResult`.

Skipping a test is simply a matter of using the `skip() decorator` or one of its conditional variants, calling `TestCase.skipTest()` within a `setUp()` or test method, or raising `SkipTest` directly.

Basic skipping looks like this:

```
class MyTestCase(unittest.TestCase):  
  
    @unittest.skip("demonstrating skipping")  
    def test_nothing(self):
```

```

        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3),
                     "not supported in this library version")
    def test_format(self):
        # Tests that work for only a certain version of mylib
        pass

    @unittest.skipUnless(sys.platform.startswith("win"),
                          "Windows specific testing code")
    def test_windows_support(self):
        # windows specific testing code
        pass

    def test_maybe_skipped(self):
        if not external_resource_available():
            self.skipTest("external resource not available")
        # test code that depends on the external resource
        pass

```

This is the output of running the example above in verbose mode:

```

test_format (__main__.MyTestCase.test_format) ... skipped
test_nothing (__main__.MyTestCase.test_nothing) ... skipped
test_maybe_skipped (__main__.MyTestCase.test_maybe_skipped) ... skipped
test_windows_support (__main__.MyTestCase.test_windows_support) ... skipped

```

---

```

Ran 4 tests in 0.005s

```

```

OK (skipped=4)

```

Classes can be skipped just like methods:

```

@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass

```

**TestCase.setUp()** can also skip the test. This is useful when a

resource that needs to be set up is not available.

Expected failures use the `expectedFailure()` decorator.

```
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls `skip()` on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
    return unittest.skip("{!r} doesn't have {!r}".format
```

The following decorators and exception implement test skipping and expected failures:

`@unittest.skip(reason)`

Unconditionally skip the decorated test. *reason* should describe why the test is being skipped.

`@unittest.skipIf(condition, reason)`

Skip the decorated test if *condition* is true.

`@unittest.skipUnless(condition, reason)`

Skip the decorated test unless *condition* is true.

`@unittest.expectedFailure`

Mark the test as an expected failure or error. If the test fails or errors in the test function itself (rather than in one of the *test fixture* methods) then it will be considered a success. If the test passes, it will be considered a failure.

*exception* `unittest.SkipTest(reason)`

This exception is raised to skip a test.

Usually you can use `TestCase.skipTest()` or one of the skipping decorators instead of raising this directly.

Skipped tests will not have `setUp()` or `tearDown()` run around them. Skipped classes will not have `setUpClass()` or `tearDownClass()` run. Skipped modules will not have `setUpModule()` or `tearDownModule()` run.

## Distinguishing test iterations using subtests

*New in version 3.4.*

When there are very small differences among your tests, for instance some parameters, `unittest` allows you to distinguish them inside the body of a test method using the `subTest()` context manager.

For example, the following test:

```
class NumbersTest(unittest.TestCase):

    def test_even(self):
        """
        Test that numbers between 0 and 5 are all even.
        """
        for i in range(0, 6):
            with self.subTest(i=i):
                self.assertEqual(i % 2, 0)
```

will produce the following output:

```
=====
FAIL: test_even (__main__.NumbersTest.test_even) (i=1)
Test that numbers between 0 and 5 are all even.
-----
```

```
Traceback (most recent call last):
  File "subtests.py", line 11, in test_even
    self.assertEqual(i % 2, 0)
    ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
AssertionError: 1 != 0
```

```
=====
FAIL: test_even (__main__.NumbersTest.test_even) (i=3)
Test that numbers between 0 and 5 are all even.
```

```
-----
Traceback (most recent call last):
  File "subtests.py", line 11, in test_even
    self.assertEqual(i % 2, 0)
    ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
AssertionError: 1 != 0
```

```
=====
FAIL: test_even (__main__.NumbersTest.test_even) (i=5)
Test that numbers between 0 and 5 are all even.
```

```
-----
Traceback (most recent call last):
  File "subtests.py", line 11, in test_even
    self.assertEqual(i % 2, 0)
    ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
AssertionError: 1 != 0
```

Without using a subtest, execution would stop after the first failure, and the error would be less easy to diagnose because the value of `i` wouldn't be displayed:

```
=====
FAIL: test_even (__main__.NumbersTest.test_even)
```

```
-----
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0
```

# Classes and functions

This section describes in depth the API of `unittest`.

## Test cases

*class* `unittest.TestCase(methodName = 'runTest')`

Instances of the `TestCase` class represent the logical test units in the `unittest` universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the tests, and methods that the test code can use to check for and report various kinds of failure.

Each instance of `TestCase` will run a single base method: the method named *methodName*. In most uses of `TestCase`, you will neither change the *methodName* nor reimplement the default `runTest()` method.

*Changed in version 3.2:* `TestCase` can be instantiated successfully without providing a *methodName*. This makes it easier to experiment with `TestCase` from the interactive interpreter.

`TestCase` instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.

Methods in the first group (running the test) are:

`setUp()`

Method called to prepare the test fixture. This is called immediately before calling the test method; other than `AssertionError` or `SkipTest`, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

## tearDown()

Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than [AssertionError](#) or [SkipTest](#), raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the [setUp\(\)](#) succeeds, regardless of the outcome of the test method. The default implementation does nothing.

## setUpClass()

A class method called before tests in an individual class are run. `setUpClass` is called with the class as the only argument and must be decorated as a [classmethod\(\)](#):

```
@classmethod
def setUpClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 3.2.*

## tearDownClass()

A class method called after tests in an individual class have run. `tearDownClass` is called with the class as the only argument and must be decorated as a [classmethod\(\)](#):

```
@classmethod
def tearDownClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 3.2.*

`run(result=None)`

Run the test, collecting the result into the `TestResult` object passed as *result*. If *result* is omitted or `None`, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is returned to `run()`'s caller.

The same effect may be had by simply calling the `TestCase` instance.

*Changed in version 3.3:* Previous versions of `run` did not return the result. Neither did calling an instance.

`skipTest(reason)`

Calling this during a test method or `setUp()` skips the current test. See [Skipping tests and expected failures](#) for more information.

*New in version 3.1.*

`subTest(msg=None, **params)`

Return a context manager which executes the enclosed code block as a subtest. *msg* and *params* are optional, arbitrary values which are displayed whenever a subtest fails, allowing you to identify them clearly.

A test case can contain any number of subtest declarations, and they can be arbitrarily nested.

See [Distinguishing test iterations using subtests](#) for more information.

*New in version 3.4.*

`debug()`

Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the

caller, and can be used to support running tests under a debugger.

The `TestCase` class provides several assert methods to check for and report failures. The following table lists the most commonly used methods (see the tables below for more assert methods):

#### Methods that

<code>assertEqual(a, b)</code>
<code>assertNotEqual(a, b)</code>
<code>assertTrue(True)</code>
<code>assertFalse(False)</code>
<code>assertIs(a, b)</code>
<code>assertIsNot(a, b)</code>
<code>assertIsNone(x)</code>
<code>assertIsNotNone(x)</code>
<code>assertIn(a, b)</code>
<code>assertNotIn(a, b)</code>
<code>assertRaises(a, b)</code>
<code>assertRaises(a, b)</code>

All the assert methods accept a *msg* argument that, if specified, is used as the error message on failure (see also `longMessage`). Note that the *msg* keyword argument can be passed to `assertRaises()`, `assertRaisesRegex()`, `assertWarns()`, `assertWarnsRegex()` only when they are used as a context manager.

`assertEqual(first, second, msg=None)`

Test that *first* and *second* are equal. If the values do not compare equal, the test will fail.

In addition, if *first* and *second* are the exact same type and one of list, tuple, dict, set, frozenset or str or any type that a subclass registers with `addTypeEqualityFunc()` the type-specific equality function will be called in order to generate a more useful default error message (see also the [list of type-specific methods](#)).

*Changed in version 3.1:* Added the automatic calling of type-specific equality function.

*Changed in version 3.2:* `assertMultiLineEqual()` added as the default type equality function for comparing strings.

`assertNotEqual(first, second, msg=None)`

Test that *first* and *second* are not equal. If the values do compare equal, the test will fail.

`assertTrue(expr, msg=None)`

`assertFalse(expr, msg=None)`

Test that *expr* is true (or false).

Note that this is equivalent to `bool(expr) is True` and not to `expr is True` (use `assertIs(expr, True)` for the latter). This method should also be avoided when more specific methods are available (e.g. `assertEqual(a, b)` instead of `assertTrue(a == b)`), because they provide a better error message in case of failure.

`assertIs(first, second, msg=None)`

`assertIsNot(first, second, msg=None)`

Test that *first* and *second* are (or are not) the same object.

*New in version 3.1.*

`assertIsNone(expr, msg=None)`

`assertIsNotNone(expr, msg=None)`

Test that *expr* is (or is not) `None`.

*New in version 3.1.*

`assertIn(member, container, msg=None)`

`assertNotIn(member, container, msg=None)`

Test that *member* is (or is not) in *container*.

*New in version 3.1.*

`assertIsInstance(obj, cls, msg=None)`

`assertNotIsInstance(obj, cls, msg=None)`

Test that *obj* is (or is not) an instance of *cls* (which can be a class or a tuple of classes, as supported by `isinstance()`). To check for the exact type, use `assertIs(type(obj), cls)`.

*New in version 3.2.*

It is also possible to check the production of exceptions, warnings, and log messages using the following methods:

#### Methods that

---

`assertRaises(exc, func, *args, **kwargs)` raises *exc*

---

`assertRaisesRegex(exc, func, *args, **kwargs, msg, regex)` raises *exc* and the message matches *regex*

---

`assertWarns(warns, func, *args, **kwargs)` raises *warns*

---

`assertWarnsRegex(warns, func, *args, **kwargs, msg, regex)` raises *warns* and the message matches *regex*

---

`assertLogBlock(logger, level, msg)` logs on *logger* with minimum *level*

---

`assertNoLogBlock(logger, level)` does not log on *logger* with minimum *level*

---

`assertRaises(exception, callable, *args, **kwargs)`

`assertRaises(exception, *, msg=None)`

Test that an exception is raised when *callable* is called with any positional or keyword arguments that are also passed to `assertRaises()`. The test passes if *exception* is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as *exception*.

If only the *exception* and possibly the *msg* arguments are

given, return a context manager so that the code under test can be written inline rather than as a function:

```
with self.assertRaises(SomeException):  
    do_something()
```

When used as a context manager, `assertRaises()` accepts the additional keyword argument *msg*.

The context manager will store the caught exception object in its **exception** attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```
with self.assertRaises(SomeException) as cm:  
    do_something()  
  
the_exception = cm.exception  
self.assertEqual(the_exception.error_code, 3)
```

*Changed in version 3.1:* Added the ability to use `assertRaises()` as a context manager.

*Changed in version 3.2:* Added the **exception** attribute.

*Changed in version 3.3:* Added the *msg* keyword argument when used as a context manager.

```
assertRaisesRegex(exception, regex, callable, *args, **kwargs)  
assertRaisesRegex(exception, regex, *, msg=None)
```

Like `assertRaises()` but also tests that *regex* matches on the string representation of the raised exception. *regex* may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`. Examples:

```
self.assertRaisesRegex(ValueError, "invalid lit  
int, 'XYZ')
```

or:

```
with self.assertRaisesRegex(ValueError, 'literal  
int('XYZ')
```

*New in version 3.1:* Added under the name `assertRaisesRegexp`.

*Changed in version 3.2:* Renamed to `assertRaisesRegex()`.

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.

```
assertWarns(warning, callable, *args, **kwargs)  
assertWarns(warning, *, msg=None)
```

Test that a warning is triggered when *callable* is called with any positional or keyword arguments that are also passed to `assertWarns()`. The test passes if *warning* is triggered and fails if it isn't. Any exception is an error. To catch any of a group of warnings, a tuple containing the warning classes may be passed as *warnings*.

If only the *warning* and possibly the *msg* arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```
with self.assertWarns(SomeWarning):  
    do_something()
```

When used as a context manager, `assertWarns()` accepts the additional keyword argument *msg*.

The context manager will store the caught warning object in its **warning** attribute, and the source line which triggered the warnings in the **filename** and **lineno** attributes. This can be useful if the intention is to perform additional checks on the warning caught:

```
with self.assertWarns(SomeWarning) as cm:  
    do_something()
```

```
self.assertIn('myfile.py', cm.filename)  
self.assertEqual(320, cm.lineno)
```

This method works regardless of the warning filters in place when it is called.

*New in version 3.2.*

*Changed in version 3.3:* Added the *msg* keyword argument when used as a context manager.

```
assertWarnsRegex(warning, regex, callable, *args, **kwargs)  
assertWarnsRegex(warning, regex, *, msg=None)
```

Like `assertWarns()` but also tests that *regex* matches on the message of the triggered warning. *regex* may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`.  
Example:

```
self.assertWarnsRegex(DeprecationWarning,  
                       r'legacy_function\(\) is  
                       legacy_function, 'XYZ')
```

or:

```
with self.assertWarnsRegex(RuntimeWarning, 'uns  
    frobnicate('/etc/passwd')
```

*New in version 3.2.*

*Changed in version 3.3:* Added the *msg* keyword argument when used as a context manager.

```
assertLogs(logger=None, level=None)
```

A context manager to test that at least one message is logged on the *logger* or one of its children, with at least the given *level*.

If given, *logger* should be a `logging.Logger` object or a `str` giving the name of a logger. The default is the root logger, which will catch all messages that were not blocked by a non-propagating descendent logger.

If given, *level* should be either a numeric logging level or its string equivalent (for example either `"ERROR"` or `logging.ERROR`). The default is `logging.INFO`.

The test passes if at least one message emitted inside the `with` block matches the *logger* and *level* conditions, otherwise it fails.

The object returned by the context manager is a recording helper which keeps tracks of the matching log messages. It has two attributes:

*records*

A list of `logging.LogRecord` objects of the matching log messages.

*output*

A list of `str` objects with the formatted output of matching messages.

Example:

```
with self.assertLogs('foo', level='INFO') as cm:
    logging.getLogger('foo').info('first message')
    logging.getLogger('foo.bar').error('second message')
self.assertEqual(cm.output, ['INFO:foo:first message',
                              'ERROR:foo.bar:second message'])
```

*New in version 3.4.*

`assertNoLogs(logger=None, level=None)`

A context manager to test that no messages are logged on the *logger* or one of its children, with at least the given *level*.

If given, *logger* should be a `logging.Logger` object or a `str` giving the name of a logger. The default is the root logger, which will catch all messages.

If given, *level* should be either a numeric logging level or its string equivalent (for example either `"ERROR"` or `logging.ERROR`). The default is `logging.INFO`.

Unlike `assertLogs()`, nothing will be returned by the context manager.

*New in version 3.10.*

There are also other methods used to perform more specific checks, such as:

#### Methods that

---

`assertAlmostEqual(a, b)`

---

`assertNotAlmostEqual(a, b)`

---

`assertGreater(a, b)`

---

`assertGreaterEqual(a, b)`

---

`assertLess(a, b)`

---

`assertLessEqual(a, b)`

---

`assertRegex(s, r)`

---

`assertNotRegex(s, r)`

---

`assertEqual(a, b)`  
and `b` have the same elements in the same order,  
regardless of their order.

`assertAlmostEqual(first, second, places=7, msg=None, delta=None)`

`assertNotAlmostEqual(first, second, places=7, msg=None, delta=None)`

Test that *first* and *second* are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal *places* (default 7), and comparing to zero. Note that these methods round the values to the given number of *decimal places* (i.e. like the `round()` function) and not *significant digits*.

If *delta* is supplied instead of *places* then the difference between *first* and *second* must be less or equal to (or greater than) *delta*.

Supplying both *delta* and *places* raises a **`TypeError`**.

*Changed in version 3.2:* **`assertAlmostEqual()`** automatically considers almost equal objects that compare equal. **`assertNotAlmostEqual()`** automatically fails if the objects compare equal. Added the *delta* keyword argument.

```
assertGreater(first, second, msg=None)
assertGreaterEqual(first, second, msg=None)
assertLess(first, second, msg=None)
assertLessEqual(first, second, msg=None)
```

Test that *first* is respectively  $>$ ,  $>=$ ,  $<$  or  $<=$  than *second* depending on the method name. If not, the test will fail:

```
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater than 4
```

*New in version 3.1.*

```
assertRegex(text, regex, msg=None)
assertNotRegex(text, regex, msg=None)
```

Test that a *regex* search matches (or does not match) *text*. In case of failure, the error message will include the pattern and the *text* (or the pattern and the part of *text* that unexpectedly matched). *regex* may be a regular expression object or a string containing a regular expression suitable for use by **`re.search()`**.

*New in version 3.1:* Added under the name **`assertRegexMatches`**.

*Changed in version 3.2:* The method **`assertRegexMatches()`** has been renamed to

`assertRegex()`.

New in version 3.2: `assertNotRegex()`.

`assertCountEqual(first, second, msg=None)`

Test that sequence *first* contains the same elements as *second*, regardless of their order. When they don't, an error message listing the differences between the sequences will be generated.

Duplicate elements are *not* ignored when comparing *first* and *second*. It verifies whether each element has the same count in both sequences. Equivalent to:  
`assertEqual(Counter(list(first)), Counter(list(second)))` but works with sequences of unhashable objects as well.

New in version 3.2.

The `assertEqual()` method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it's also possible to register new methods using `addTypeEqualityFunc()`:

`addTypeEqualityFunc(typeobj, function)`

Registers a type-specific method called by `assertEqual()` to check if two objects of exactly the same *typeobj* (not subclasses) compare equal. *function* must take two positional arguments and a third `msg=None` keyword argument just as `assertEqual()` does. It must raise `self.failureException(msg)` when inequality between the first two parameters is detected – possibly providing useful information and explaining the inequalities in details in the error message.

New in version 3.1.

The list of type-specific methods automatically used by

`assertEqual()` are summarized in the following table. Note that it's usually not necessary to invoke these methods directly.

### Method compare

Strings	<code>assertMultiLineEqual(a, b)</code>
Sequences	<code>assertSequenceEqual(a, b)</code>
Lists	<code>assertListEqual(a, b)</code>
Tuples	<code>assertTupleEqual(a, b)</code>
Sets or frozensets	<code>assertSetEqual(a, b)</code>
Dicts	<code>assertDictEqual(a, b)</code>

`assertMultiLineEqual(first, second, msg=None)`

Test that the multiline string *first* is equal to the string *second*. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with `assertEqual()`.

*New in version 3.1.*

`assertSequenceEqual(first, second, msg=None, seq_type=None)`

Tests that two sequences are equal. If a *seq\_type* is supplied, both *first* and *second* must be instances of *seq\_type* or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.

This method is not called directly by `assertEqual()`, but it's used to implement `assertListEqual()` and `assertTupleEqual()`.

*New in version 3.1.*

`assertListEqual(first, second, msg=None)`

`assertTupleEqual(first, second, msg=None)`

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the

parameters are of the wrong type. These methods are used by default when comparing lists or tuples with `assertEqual()`.

*New in version 3.1.*

`assertSetEqual(first, second, msg=None)`

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with `assertEqual()`.

Fails if either of *first* or *second* does not have a `set.difference()` method.

*New in version 3.1.*

`assertDictEqual(first, second, msg=None)`

Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to `assertEqual()`.

*New in version 3.1.*

Finally the `TestCase` provides the following methods and attributes:

`fail(msg=None)`

Signals a test failure unconditionally, with *msg* or `None` for the error message.

`failureException`

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to “play fair” with the framework. The initial value of this attribute is `AssertionError`.

## longMessage

This class attribute determines what happens when a custom failure message is passed as the `msg` argument to an `assertXXX` call that fails. `True` is the default value. In this case, the custom message is appended to the end of the standard failure message. When set to `False`, the custom message replaces the standard message.

The class setting can be overridden in individual test methods by assigning an instance attribute, `self.longMessage`, to `True` or `False` before calling the assert methods.

The class setting gets reset before each test call.

*New in version 3.1.*

## maxDiff

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80\*8 characters. Assert methods affected by this attribute are `assertSequenceEqual()` (including all the sequence comparison methods that delegate to it), `assertDictEqual()` and `assertMultiLineEqual()`.

Setting `maxDiff` to `None` means that there is no maximum length of diffs.

*New in version 3.2.*

Testing frameworks can use the following methods to collect information on the test:

## countTestCases()

Return the number of tests represented by this test object. For `TestCase` instances, this will always be 1.

## defaultTestResult()

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the `run()` method).

For `TestCase` instances, this will always be an instance of `TestResult`; subclasses of `TestCase` should override this as necessary.

## id()

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

## shortDescription()

Returns a description of the test, or `None` if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or `None`.

*Changed in version 3.1:* In 3.1 this was changed to add the test name to the short description even in the presence of a docstring. This caused compatibility issues with unittest extensions and adding the test name was moved to the `TextTestResult` in Python 3.2.

## addCleanup(function, /, \*args, \*\*kwargs)

Add a function to be called after `tearDown()` to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addCleanup()` when they are added.

If `setUp()` fails, meaning that `tearDown()` is not called, then any cleanup functions added will still be called.

*New in version 3.1.*

`enterContext(cm)`

Enter the supplied `context manager`. If successful, also add its `__exit__()` method as a cleanup function by `addCleanup()` and return the result of the `__enter__()` method.

*New in version 3.11.*

`doCleanups()`

This method is called unconditionally after `tearDown()`, or after `setUp()` if `setUp()` raises an exception.

It is responsible for calling all the cleanup functions added by `addCleanup()`. If you need cleanup functions to be called *prior* to `tearDown()` then you can call `doCleanups()` yourself.

`doCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

*New in version 3.1.*

*classmethod* `addClassCleanup(function, /, *args, **kwargs)`

Add a function to be called after `tearDownClass()` to cleanup resources used during the test class. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addClassCleanup()` when they are added.

If `setUpClass()` fails, meaning that `tearDownClass()` is not called, then any cleanup functions added will still be called.

*New in version 3.8.*

*classmethod* enterClassContext(*cm*)

Enter the supplied [context manager](#). If successful, also add its `__exit__()` method as a cleanup function by `addClassCleanup()` and return the result of the `__enter__()` method.

*New in version 3.11.*

*classmethod* doClassCleanups()

This method is called unconditionally after `tearDownClass()`, or after `setUpClass()` if `setUpClass()` raises an exception.

It is responsible for calling all the cleanup functions added by `addClassCleanup()`. If you need cleanup functions to be called *prior* to `tearDownClass()` then you can call `doClassCleanups()` yourself.

`doClassCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

*New in version 3.8.*

*class* unittest.IsolatedAsyncioTestCase(*methodName* = 'runTest')

This class provides an API similar to [TestCase](#) and also accepts coroutines as test functions.

*New in version 3.8.*

*coroutine* asyncSetUp()

Method called to prepare the test fixture. This is called after `setUp()`. This is called immediately before calling the test method; other than [AssertionError](#) or [SkipTest](#), any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

*coroutine* asyncTearDown()

Method called immediately after the test method has been called and the result recorded. This is called before `tearDown()`. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than `AssertionError` or `SkipTest`, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the `asyncSetUp()` succeeds, regardless of the outcome of the test method. The default implementation does nothing.

`addAsyncCleanup(function, /, *args, **kwargs)`

This method accepts a coroutine that can be used as a cleanup function.

*coroutine* `enterAsyncContext(cm)`

Enter the supplied [asynchronous context manager](#). If successful, also add its `__aexit__()` method as a cleanup function by `addAsyncCleanup()` and return the result of the `__aenter__()` method.

*New in version 3.11.*

`run(result=None)`

Sets up a new event loop to run the test, collecting the result into the `TestResult` object passed as *result*. If *result* is omitted or `None`, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is returned to `run()`'s caller. At the end of the test all the tasks in the event loop are cancelled.

An example illustrating the order:

```
from unittest import IsolatedAsyncioTestCase
```

```
events = []
```

```
class Test(IsolatedAsyncioTestCase):
```

```
    def setUp(self):  
        events.append("setUp")
```

```
    async def asyncSetUp(self):  
        self._async_connection = await AsyncConnect  
        events.append("asyncSetUp")
```

```
    async def test_response(self):  
        events.append("test_response")  
        response = await self._async_connection.get  
        self.assertEqual(response.status_code, 200)  
        self.addAsyncCleanup(self.on_cleanup)
```

```
    def tearDown(self):  
        events.append("tearDown")
```

```
    async def asyncTearDown(self):  
        await self._async_connection.close()  
        events.append("asyncTearDown")
```

```
    async def on_cleanup(self):  
        events.append("cleanup")
```

```
if __name__ == "__main__":  
    unittest.main()
```

After running the test, events would contain ["setUp", "asyncSetUp", "test\_response", "asyncTearDown", "tearDown", "cleanup"].

*class unittest.FunctionTestCase(testFunc, setUp=None,*

*tearDown = None, description = None)*

This class implements the portion of the **TestCase** interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a **unittest**-based test framework.

## Grouping tests

*class unittest.TestSuite(tests = ())*

This class represents an aggregation of individual test cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a **TestSuite** instance is the same as iterating over the suite, running each test individually.

If *tests* is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

**TestSuite** objects behave much like **TestCase** objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to **TestSuite** instances:

*addTest(test)*

Add a **TestCase** or **TestSuite** to the suite.

*addTests(tests)*

Add all the tests from an iterable of **TestCase** and **TestSuite** instances to this test suite.

This is equivalent to iterating over *tests*, calling **addTest()** for each element.

**TestSuite** shares the following methods with **TestCase**:

**run(result)**

Run the tests associated with this suite, collecting the result into the test result object passed as *result*. Note that unlike **TestCase.run()**, **TestSuite.run()** requires the result object to be passed in.

**debug()**

Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

**countTestCases()**

Return the number of tests represented by this test object, including all individual tests and sub-suites.

**\_\_iter\_\_()**

Tests grouped by a **TestSuite** are always accessed by iteration. Subclasses can lazily provide tests by overriding **\_\_iter\_\_()**. Note that this method may be called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned by repeated iterations before **TestSuite.run()** must be the same for each call iteration. After **TestSuite.run()**, callers should not rely on the tests returned by this method unless the caller uses a subclass that overrides **TestSuite.\_removeTestAtIndex()** to preserve test references.

*Changed in version 3.2:* In earlier versions the **TestSuite** accessed tests directly rather than through iteration, so overriding **\_\_iter\_\_()** wasn't sufficient for providing tests.

*Changed in version 3.4:* In earlier versions the

**TestSuite** held references to each **TestCase** after **TestSuite.run()**. Subclasses can restore that behavior by overriding **TestSuite.\_removeTestAtIndex()**.

In the typical usage of a **TestSuite** object, the **run()** method is invoked by a **TestRunner** rather than by the end-user test harness.

## Loading and running tests

*class* unittest.TestLoader

The **TestLoader** class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the **unittest** module provides an instance that can be shared as **unittest.defaultTestLoader**. Using a subclass or instance, however, allows customization of some configurable properties.

**TestLoader** objects have the following attributes:

errors

A list of the non-fatal errors encountered while loading tests. Not reset by the loader at any point. Fatal errors are signalled by the relevant method raising an exception to the caller. Non-fatal errors are also indicated by a synthetic test that will raise the original error when run.

*New in version 3.5.*

**TestLoader** objects have the following methods:

loadTestsFromTestCase(*testCaseClass*)

Return a suite of all test cases contained in the **TestCase**-derived **testCaseClass**.

A test case instance is created for each method named

by `getTestCaseNames()`. By default these are the method names beginning with `test`. If `getTestCaseNames()` returns no methods, but the `runTest()` method is implemented, a single test case is created for that method instead.

`loadTestsFromModule(module, *, pattern=None)`

Return a suite of all test cases contained in the given module. This method searches *module* for classes derived from `TestCase` and creates an instance of the class for each test method defined for the class.

### Note

While using a hierarchy of `TestCase`-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

If a module provides a `load_tests` function it will be called to load the tests. This allows modules to customize test loading. This is the [load\\_tests protocol](#). The *pattern* argument is passed as the third argument to `load_tests`.

*Changed in version 3.2:* Support for `load_tests` added.

*Changed in version 3.5:* Support for a keyword-only argument *pattern* has been added.

*Changed in version 3.12:* The undocumented and unofficial *use\_load\_tests* parameter has been removed.

`loadTestsFromName(name, module=None)`

Return a suite of all test cases given a string specifier.

The specifier *name* is a “dotted name” that may resolve either to a module, a test case class, a test method within a test case class, a **TestSuite** instance, or a callable object which returns a **TestCase** or **TestSuite** instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as “a test method within a test case class”, rather than “a callable object”.

For example, if you have a module **SampleTests** containing a **TestCase**-derived class **SampleTestCase** with three test methods (**test\_one()**, **test\_two()**, and **test\_three()**), the specifier `'SampleTests.SampleTestCase'` would cause this method to return a suite which will run all three test methods. Using the specifier `'SampleTests.SampleTestCase.test_two'` would cause it to return a test suite which will run only the **test\_two()** test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves *name* relative to the given *module*.

*Changed in version 3.5:* If an **ImportError** or **AttributeError** occurs while traversing *name* then a synthetic test that raises that error when run will be returned. These errors are included in the errors accumulated by `self.errors`.

**loadTestsFromNames**(*names*, *module* = *None*)

Similar to **loadTestsFromName()**, but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

**getTestCaseNames**(*testCaseClass*)

Return a sorted sequence of method names found

within *testCaseClass*; this should be a subclass of **TestCase**.

`discover(start_dir, pattern='test*.py', top_level_dir=None)`

Find all the test modules by recursing into subdirectories from the specified start directory, and return a `TestSuite` object containing them. Only test files that match *pattern* will be loaded. (Using shell style pattern matching.) Only module names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue. If the import failure is due to **SkipTest** being raised, it will be recorded as a skip instead of an error.

If a package (a directory containing a file named `__init__.py`) is found, the package will be checked for a `load_tests` function. If this exists then it will be called `package.load_tests(loader, tests, pattern)`. Test discovery takes care to ensure that a package is only checked for tests once during an invocation, even if the `load_tests` function itself calls `loader.discover`.

If `load_tests` exists then discovery does *not* recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. *top\_level\_dir* is stored so `load_tests` does not need to pass this argument in to

```
loader.discover().
```

`start_dir` can be a dotted module name as well as a directory.

*New in version 3.2.*

*Changed in version 3.4:* Modules that raise `SkipTest` on import are recorded as skips, not errors.

*Changed in version 3.4:* `start_dir` can be a `namespace packages`.

*Changed in version 3.4:* Paths are sorted before being imported so that execution order is the same even if the underlying file system's ordering is not dependent on file name.

*Changed in version 3.5:* Found packages are now checked for `load_tests` regardless of whether their path matches *pattern*, because it is impossible for a package name to match the default pattern.

*Changed in version 3.11:* `start_dir` can not be a `namespace packages`. It has been broken since Python 3.7 and Python 3.11 officially remove it.

The following attributes of a `TestLoader` can be configured either by subclassing or assignment on an instance:

`testMethodPrefix`

String giving the prefix of method names which will be interpreted as test methods. The default value is `'test'`.

This affects `getTestCaseNames()` and all the `loadTestsFrom*` methods.

`sortTestMethodsUsing`

Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the

**loadTestsFrom\* ()** methods.

#### suiteClass

Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the **TestSuite** class.

This affects all the **loadTestsFrom\* ()** methods.

#### testNamePatterns

List of Unix shell-style wildcard test name patterns that test methods have to match to be included in test suites (see `-k` option).

If this attribute is not `None` (the default), all test methods to be included in test suites must match one of the patterns in this list. Note that matches are always performed using **fnmatch.fnmatchcase ()**, so unlike patterns passed to the `-k` option, simple substring patterns will have to be converted using `*` wildcards.

This affects all the **loadTestsFrom\* ()** methods.

*New in version 3.7.*

#### class unittest.TestResult

This class is used to compile information about which tests have succeeded and which have failed.

A **TestResult** object stores the results of a set of tests. The **TestCase** and **TestSuite** classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of **unittest** may want access to the **TestResult** object generated by running a set of tests for reporting purposes; a **TestResult** instance is returned by the **TestRunner.run ()** method for this purpose.

**TestResult** instances have the following attributes that will be of interest when inspecting the results of running a set of tests:

#### errors

A list containing 2-tuples of **TestCase** instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

#### failures

A list containing 2-tuples of **TestCase** instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the **TestCase.assert\*()** methods.

#### skipped

A list containing 2-tuples of **TestCase** instances and strings holding the reason for skipping the test.

*New in version 3.1.*

#### expectedFailures

A list containing 2-tuples of **TestCase** instances and strings holding formatted tracebacks. Each tuple represents an expected failure or error of the test case.

#### unexpectedSuccesses

A list containing **TestCase** instances that were marked as expected failures, but succeeded.

#### collectedDurations

A list containing 2-tuples of test case names and floats representing the elapsed time of each test which was run.

*New in version 3.12.*

#### shouldStop

Set to `True` when the execution of tests should stop by `stop()`.

`testsRun`

The total number of tests run so far.

`buffer`

If set to `true`, `sys.stdout` and `sys.stderr` will be buffered in between `startTest()` and `stopTest()` being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

*New in version 3.2.*

`failfast`

If set to `true` `stop()` will be called on the first failure or error, halting the test run.

*New in version 3.2.*

`tb_locals`

If set to `true` then local variables will be shown in tracebacks.

*New in version 3.5.*

`wasSuccessful()`

Return `True` if all tests run so far have passed, otherwise returns `False`.

*Changed in version 3.4:* Returns `False` if there were any `unexpectedSuccesses` from tests marked with the `expectedFailure()` decorator.

`stop()`

This method can be called to signal that the set of tests

being run should be aborted by setting the `shouldStop` attribute to `True`. **TestRunner** objects should respect this flag and return without running any additional tests.

For example, this feature is used by the **TextTestRunner** class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide **TestRunner** implementations can use this in a similar manner.

The following methods of the **TestResult** class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

`startTest(test)`

Called when the test case *test* is about to be run.

`stopTest(test)`

Called after the test case *test* has been executed, regardless of the outcome.

`startTestRun()`

Called once before any tests are executed.

*New in version 3.1.*

`stopTestRun()`

Called once after all tests are executed.

*New in version 3.1.*

`addError(test, err)`

Called when the test case *test* raises an unexpected exception. *err* is a tuple of the form returned by `sys.exc_info()`: (type, value, traceback).

The default implementation appends a tuple `(test, formatted_err)` to the instance's **errors** attribute, where *formatted\_err* is a formatted traceback derived from *err*.

### `addFailure(test, err)`

Called when the test case *test* signals a failure. *err* is a tuple of the form returned by `sys.exc_info()`:  
(type, value, traceback).

The default implementation appends a tuple `(test, formatted_err)` to the instance's **failures** attribute, where *formatted\_err* is a formatted traceback derived from *err*.

### `addSuccess(test)`

Called when the test case *test* succeeds.

The default implementation does nothing.

### `addSkip(test, reason)`

Called when the test case *test* is skipped. *reason* is the reason the test gave for skipping.

The default implementation appends a tuple `(test, reason)` to the instance's **skipped** attribute.

### `addExpectedFailure(test, err)`

Called when the test case *test* fails or errors, but was marked with the **expectedFailure()** decorator.

The default implementation appends a tuple `(test, formatted_err)` to the instance's **expectedFailures** attribute, where *formatted\_err* is a formatted traceback derived from *err*.

### `addUnexpectedSuccess(test)`

Called when the test case *test* was marked with the

**expectedFailure()** decorator, but succeeded.

The default implementation appends the test to the instance's **unexpectedSuccesses** attribute.

**addSubTest(*test*, *subtest*, *outcome*)**

Called when a subtest finishes. *test* is the test case corresponding to the test method. *subtest* is a custom **TestCase** instance describing the subtest.

If *outcome* is **None**, the subtest succeeded. Otherwise, it failed with an exception where *outcome* is a tuple of the form returned by **sys.exc\_info()**: (type, value, traceback).

The default implementation does nothing when the outcome is a success, and records subtest failures as normal failures.

*New in version 3.4.*

**addDuration(*test*, *elapsed*)**

Called when the test case finishes. *elapsed* is the time represented in seconds, and it includes the execution of cleanup functions.

*New in version 3.12.*

**class unittest.TextTestResult(*stream*, *descriptions*, *verbosity*, \*, *durations* = None)**

A concrete implementation of **TestResult** used by the **TextTestRunner**. Subclasses should accept **\*\*kwargs** to ensure compatibility as the interface changes.

*New in version 3.2.*

*New in version 3.12:* Added *durations* keyword argument.

**unittest.defaultTestLoader**

Instance of the `TestLoader` class intended to be shared. If no customization of the `TestLoader` is needed, this instance can be used instead of repeatedly creating new instances.

```
class unittest.TextTestRunner(stream=None, descriptions=True,
    verbosity=1, failfast=False, buffer=False, resultclass=None,
    warnings=None, *, tb_locals=False, durations=None)
```

A basic test runner implementation that outputs results to a stream. If *stream* is `None`, the default, `sys.stderr` is used as the output stream. This class has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations. Such implementations should accept `**kwargs` as the interface to construct runners changes when features are added to unittest.

By default this runner shows `DeprecationWarning`, `PendingDeprecationWarning`, `ResourceWarning` and `ImportWarning` even if they are ignored by default. This behavior can be overridden using Python's `-Wd` or `-Wa` options (see [Warning control](#)) and leaving *warnings* to `None`.

*Changed in version 3.2:* Added the *warnings* parameter.

*Changed in version 3.2:* The default stream is set to `sys.stderr` at instantiation time rather than import time.

*Changed in version 3.5:* Added the *tb\_locals* parameter.

*Changed in version 3.12:* Added the *durations* parameter.

`_makeResult()`

This method returns the instance of `TestResult` used by `run()`. It is not intended to be called directly, but can be overridden in subclasses to provide a custom `TestResult`.

`_makeResult()` instantiates the class or callable passed in the `TextTestRunner` constructor as the *resultclass* argument. It defaults to

**TextTestResult** if no `resultclass` is provided. The result class is instantiated with the following arguments:

```
stream, descriptions, verbosity
```

**run(*test*)**

This method is the main public interface to the `TextTestRunner`. This method takes a **TestSuite** or **TestCase** instance. A **TestResult** is created by calling **\_makeResult()** and the test(s) are run and the results printed to stdout.

```
unittest.main(module='_main_', defaultTest=None, argv=None,
testRunner=None, testLoader=unittest.defaultTestLoader, exit=True,
verbosity=1, failfast=None, catchbreak=None, buffer=None,
warnings=None)
```

A command-line program that loads a set of tests from *module* and runs them; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:

```
if __name__ == '__main__':
    unittest.main()
```

You can run tests with more detailed information by passing in the verbosity argument:

```
if __name__ == '__main__':
    unittest.main(verbosity=2)
```

The *defaultTest* argument is either the name of a single test or an iterable of test names to run if no test names are specified via *argv*. If not specified or `None` and no test names are provided via *argv*, all tests found in *module* are run.

The *argv* argument can be a list of options passed to the program, with the first element being the program name. If not specified or `None`, the values of **sys.argv** are used.

The *testRunner* argument can either be a test runner class or an already created instance of it. By default `main` calls `sys.exit()` with an exit code indicating success (0) or failure (1) of the tests run. An exit code of 5 indicates that no tests were run.

The *testLoader* argument has to be a `TestLoader` instance, and defaults to `defaultTestLoader`.

`main` supports being used from the interactive interpreter by passing in the argument `exit=False`. This displays the result on standard output without calling `sys.exit()`:

```
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The *failfast*, *catchbreak* and *buffer* parameters have the same effect as the same-name [command-line options](#).

The *warnings* argument specifies the [warning filter](#) that should be used while running the tests. If it's not specified, it will remain `None` if a `-w` option is passed to `python` (see [Warning control](#)), otherwise it will be set to `'default'`.

Calling `main` actually returns an instance of the `TestProgram` class. This stores the result of the tests run as the `result` attribute.

*Changed in version 3.1:* The *exit* parameter was added.

*Changed in version 3.2:* The *verbosity*, *failfast*, *catchbreak*, *buffer* and *warnings* parameters were added.

*Changed in version 3.4:* The *defaultTest* parameter was changed to also accept an iterable of test names.

## load\_tests Protocol

*New in version 3.2.*

Modules or packages can customize how tests are loaded from them

during normal test runs or test discovery by implementing a function called `load_tests`.

If a test module defines `load_tests` it will be called by `TestLoader.loadTestsFromModule()` with the following arguments:

```
load_tests(loader, standard_tests, pattern)
```

where *pattern* is passed straight through from `loadTestsFromModule`. It defaults to `None`.

It should return a `TestSuite`.

*loader* is the instance of `TestLoader` doing the loading. *standard\_tests* are the tests that would be loaded by default from the module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical `load_tests` function that loads tests from a specific set of `TestCase` classes may look like:

```
test_cases = (TestCase1, TestCase2, TestCase3)

def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        tests = loader.loadTestsFromTestCase(test_class)
        suite.addTests(tests)
    return suite
```

If discovery is started in a directory containing a package, either from the command line or by calling `TestLoader.discover()`, then the package `__init__.py` will be checked for `load_tests`. If that function does not exist, discovery will recurse into the package as though it were just another directory. Otherwise, discovery of the package's tests will be left up to `load_tests` which is called with the following arguments:

```
load_tests(loader, standard_tests, pattern)
```

This should return a **TestSuite** representing all the tests from the package. (`standard_tests` will only contain tests collected from `__init__.py`.)

Because the pattern is passed into `load_tests` the package is free to continue (and potentially modify) test discovery. A ‘do nothing’ `load_tests` function for a test package would look like:

```
def load_tests(loader, standard_tests, pattern):
    # top level directory cached on loader instance
    this_dir = os.path.dirname(__file__)
    package_tests = loader.discover(start_dir=this_dir,
    standard_tests.addTests(package_tests)
    return standard_tests
```

*Changed in version 3.5:* Discovery no longer checks package names for matching *pattern* due to the impossibility of package names matching the default pattern.

## Class and Module Fixtures

Class and module level fixtures are implemented in **TestSuite**. When the test suite encounters a test from a new class then **`tearDownClass()`** from the previous class (if there is one) is called, followed by **`setUpClass()`** from the new class.

Similarly if a test is from a different module from the previous test then `tearDownModule` from the previous module is run, followed by `setUpModule` from the new module.

After all the tests have run the final `tearDownClass` and `tearDownModule` are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to `setUpClass` / `setUpModule` (etc) being called

exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A `BaseTestSuite` still exists for frameworks that don't want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no corresponding test instance an `_ErrorHandler` object (that has the same interface as a `TestCase`) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn't matter, but if you are a framework author it may be relevant.

## setUpClass and tearDownClass

These must be implemented as class methods:

```
import unittest

class Test(unittest.TestCase):
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObject()

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the `setUpClass` and `tearDownClass` on base classes called then you must call up to them yourself. The implementations in `TestCase` are empty.

If an exception is raised during a `setUpClass` then the tests in the class are not run and the `tearDownClass` is not run. Skipped classes will not have `setUpClass` or `tearDownClass` run. If the exception is a `SkipTest` exception then the class will be reported

as having been skipped instead of as an error.

## setUpModule and tearDownModule

These should be implemented as functions:

```
def setUpModule():
    createConnection()

def tearDownModule():
    closeConnection()
```

If an exception is raised in a `setUpModule` then none of the tests in the module will be run and the `tearDownModule` will not be run. If the exception is a `SkipTest` exception then the module will be reported as having been skipped instead of as an error.

To add cleanup code that must be run even in the case of an exception, use `addModuleCleanup`:

`unittest.addModuleCleanup(function, /, *args, **kwargs)`

Add a function to be called after `tearDownModule()` to cleanup resources used during the test class. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addModuleCleanup()` when they are added.

If `setUpModule()` fails, meaning that `tearDownModule()` is not called, then any cleanup functions added will still be called.

*New in version 3.8.*

`classmethod unittest.enterModuleContext(cm)`

Enter the supplied `context manager`. If successful, also add its `__exit__()` method as a cleanup function by `addModuleCleanup()` and return the result of the `__enter__()` method.

*New in version 3.11.*

`unittest.doModuleCleanups()`

This function is called unconditionally after `tearDownModule()`, or after `setUpModule()` if `setUpModule()` raises an exception.

It is responsible for calling all the cleanup functions added by `addModuleCleanup()`. If you need cleanup functions to be called *prior* to `tearDownModule()` then you can call `doModuleCleanups()` yourself.

`doModuleCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

*New in version 3.8.*

## Signal Handling

*New in version 3.2.*

The `-c/--catch` command-line option to `unittest`, along with the `catchbreak` parameter to `unittest.main()`, provide more friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a `KeyboardInterrupt` in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own `signal.SIGINT` handler. If the `unittest` handler is called but *isn't* the installed `signal.SIGINT` handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need `unittest` control-c handling disabled the `removeHandler()` decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

`unittest.installHandler()`

Install the control-c handler. When a `signal.SIGINT` is received (usually in response to the user pressing control-c) all registered results have `stop()` called.

`unittest.registerResult(result)`

Register a `TestResult` object for control-c handling. Registering a result stores a weak reference to it, so it doesn't prevent the result from being garbage collected.

Registering a `TestResult` object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

`unittest.removeResult(result)`

Remove a registered result. Once a result has been removed then `stop()` will no longer be called on that result object in response to a control-c.

`unittest.removeHandler(function=None)`

When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler while the test is being executed:

```
@unittest.removeHandler
def test_signal_handling(self):
    ...
```

# unittest.mock — mock object library

*New in version 3.3.*

**Source code:** [Lib/unittest/mock.py](https://github.com/python/cpython/tree/3.12/Lib/unittest/mock.py) [https://github.com/python/cpython/tree/3.12/Lib/unittest/mock.py]

---

**unittest.mock** is a library for testing in Python. It allows you to replace parts of your system under test with mock objects and make assertions about how they have been used.

**unittest.mock** provides a core **Mock** class removing the need to create a host of stubs throughout your test suite. After performing an action, you can make assertions about which methods / attributes were used and arguments they were called with. You can also specify return values and set needed attributes in the normal way.

Additionally, mock provides a **patch()** decorator that handles patching module and class level attributes within the scope of a test, along with **sentinel** for creating unique objects. See the [quick guide](#) for some examples of how to use **Mock**, **MagicMock** and **patch()**.

Mock is designed for use with **unittest** and is based on the ‘action -> assertion’ pattern instead of ‘record -> replay’ used by many mocking frameworks.

There is a backport of **unittest.mock** for earlier versions of Python, available as [mock on PyPI](https://pypi.org/project/mock) [https://pypi.org/project/mock].

## Quick Guide

**Mock** and **MagicMock** objects create all attributes and methods as

you access them and store details of how they have been used. You can configure them, to specify return values or limit what attributes are available, and then make assertions about how they have been used:

```
>>> from unittest.mock import MagicMock
>>> thing = ProductionClass()
>>> thing.method = MagicMock(return_value=3)
>>> thing.method(3, 4, 5, key='value')
3
>>> thing.method.assert_called_with(3, 4, 5, key='value')
```

**side\_effect** allows you to perform side effects, including raising an exception when a mock is called:

```
>>> from unittest.mock import Mock
>>> mock = Mock(side_effect=KeyError('foo'))
>>> mock()
Traceback (most recent call last):
...
KeyError: 'foo'

>>> values = {'a': 1, 'b': 2, 'c': 3}
>>> def side_effect(arg):
...     return values[arg]
...
>>> mock.side_effect = side_effect
>>> mock('a'), mock('b'), mock('c')
(1, 2, 3)
>>> mock.side_effect = [5, 4, 3, 2, 1]
>>> mock(), mock(), mock()
(5, 4, 3)
```

Mock has many other ways you can configure it and control its behaviour. For example the *spec* argument configures the mock to take its specification from another object. Attempting to access attributes or methods on the mock that don't exist on the spec will fail with an **AttributeError**.

The **patch()** decorator / context manager makes it easy to mock

classes or objects in a module under test. The object you specify will be replaced with a mock (or other object) during the test and restored when the test ends:

```
>>> from unittest.mock import patch
>>> @patch('module.ClassName2')
... @patch('module.ClassName1')
... def test(MockClass1, MockClass2):
...     module.ClassName1()
...     module.ClassName2()
...     assert MockClass1 is module.ClassName1
...     assert MockClass2 is module.ClassName2
...     assert MockClass1.called
...     assert MockClass2.called
...
>>> test()
```

## Note

When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal *Python* order that decorators are applied). This means from the bottom up, so in the example above the mock for `module.ClassName1` is passed in first.

With `patch()` it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read [where to patch](#).

As well as a decorator `patch()` can be used as a context manager in a `with` statement:

```
>>> with patch.object(ProductionClass, 'method', return_
...     thing = ProductionClass()
...     thing.method(1, 2, 3)
...
>>> mock_method.assert_called_once_with(1, 2, 3)
```

There is also `patch.dict()` for setting values in a dictionary just

during a scope and restoring the dictionary to its original state when the test ends:

```
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True):
...     assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == original
```

Mock supports the mocking of Python [magic methods](#). The easiest way of using magic methods is with the [MagicMock](#) class. It allows you to do things like:

```
>>> mock = MagicMock()
>>> mock.__str__.return_value = 'foobarbaz'
>>> str(mock)
'foobarbaz'
>>> mock.__str__.assert_called_with()
```

Mock allows you to assign functions (or other Mock instances) to magic methods and they will be called appropriately. The [MagicMock](#) class is just a Mock variant that has all of the magic methods pre-created for you (well, all the useful ones anyway).

The following is an example of using magic methods with the ordinary Mock class:

```
>>> mock = Mock()
>>> mock.__str__ = Mock(return_value='whewheewheew')
>>> str(mock)
'whewheewheew'
```

For ensuring that the mock objects in your tests have the same api as the objects they are replacing, you can use [auto-speccing](#). Auto-speccing can be done through the *autospec* argument to patch, or the [create\\_autospec\(\)](#) function. Auto-speccing creates mock objects that have the same attributes and methods as the objects they are replacing, and any functions and methods (including constructors) have the same call signature as the real object.

This ensures that your mocks will fail in the same way as your production code if they are used incorrectly:

```
>>> from unittest.mock import create_autospec
>>> def function(a, b, c):
...     pass
...
>>> mock_function = create_autospec(function, return_value=1)
>>> mock_function(1, 2, 3)
'fishy'
>>> mock_function.assert_called_once_with(1, 2, 3)
>>> mock_function('wrong arguments')
Traceback (most recent call last):
...
TypeError: <lambda>() takes exactly 3 arguments (1 given)
```

`create_autospec()` can also be used on classes, where it copies the signature of the `__init__` method, and on callable objects where it copies the signature of the `__call__` method.

## The Mock Class

**Mock** is a flexible mock object intended to replace the use of stubs and test doubles throughout your code. Mocks are callable and create attributes as new mocks when you access them [1](#). Accessing the same attribute will always return the same mock. Mocks record how you use them, allowing you to make assertions about what your code has done to them.

**MagicMock** is a subclass of **Mock** with all the magic methods pre-created and ready to use. There are also non-callable variants, useful when you are mocking out objects that aren't callable: **NonCallableMock** and **NonCallableMagicMock**

The `patch()` decorators makes it easy to temporarily replace classes in a particular module with a **Mock** object. By default `patch()` will create a **MagicMock** for you. You can specify an alternative class of **Mock** using the `new_callable` argument to `patch()`.

```
class unittest.mock.Mock(spec=None, side_effect=None,
return_value=DEFAULT, wraps=None, name=None, spec_set=None,
unsafe=False, **kwargs)
```

Create a new **Mock** object. **Mock** takes several optional arguments that specify the behaviour of the Mock object:

- **spec**: This can be either a list of strings or an existing object (a class or instance) that acts as the specification for the mock object. If you pass in an object then a list of strings is formed by calling `dir` on the object (excluding unsupported magic attributes and methods). Accessing any attribute not in this list will raise an **AttributeError**.

If **spec** is an object (rather than a list of strings) then **\_\_class\_\_** returns the class of the spec object. This allows mocks to pass **isinstance()** tests.

- **spec\_set**: A stricter variant of **spec**. If used, attempting to set or get an attribute on the mock that isn't on the object passed as **spec\_set** will raise an **AttributeError**.
- **side\_effect**: A function to be called whenever the Mock is called. See the **side\_effect** attribute. Useful for raising exceptions or dynamically changing return values. The function is called with the same arguments as the mock, and unless it returns **DEFAULT**, the return value of this function is used as the return value.

Alternatively **side\_effect** can be an exception class or instance. In this case the exception will be raised when the mock is called.

If **side\_effect** is an iterable then each call to the mock will return the next value from the iterable.

A **side\_effect** can be cleared by setting it to `None`.

- **return\_value**: The value returned when the mock is called. By default this is a new Mock (created on first

access). See the `return_value` attribute.

- *unsafe*: By default, accessing any attribute whose name starts with *assert*, *assert*, *assert*, *assert* or *assert* will raise an `AttributeError`. Passing `unsafe=True` will allow access to these attributes.

*New in version 3.5.*

- *wraps*: Item for the mock object to wrap. If *wraps* is not `None` then calling the Mock will pass the call through to the wrapped object (returning the real result). Attribute access on the mock will return a Mock object that wraps the corresponding attribute of the wrapped object (so attempting to access an attribute that doesn't exist will raise an `AttributeError`).

If the mock has an explicit *return\_value* set then calls are not passed to the wrapped object and the *return\_value* is returned instead.

- *name*: If the mock has a name then it will be used in the repr of the mock. This can be useful for debugging. The name is propagated to child mocks.

Mocks can also be called with arbitrary keyword arguments. These will be used to set attributes on the mock after it is created. See the `configure_mock()` method for details.

`assert_called()`

Assert that the mock was called at least once.

```
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called()
```

*New in version 3.6.*

`assert_called_once()`

Assert that the mock was called exactly once.

```
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='... '>
>>> mock.method.assert_called_once()
>>> mock.method()
<Mock name='mock.method()' id='... '>
>>> mock.method.assert_called_once()
Traceback (most recent call last):
...
AssertionError: Expected 'method' to have been
```

*New in version 3.6.*

`assert_called_with(*args, **kwargs)`

This method is a convenient way of asserting that the last call has been made in a particular way:

```
>>> mock = Mock()
>>> mock.method(1, 2, 3, test='wow')
<Mock name='mock.method()' id='... '>
>>> mock.method.assert_called_with(1, 2, 3, test='wow')
```

`assert_called_once_with(*args, **kwargs)`

Assert that the mock was called exactly once and that call was with the specified arguments.

```
>>> mock = Mock(return_value=None)
>>> mock('foo', bar='baz')
>>> mock.assert_called_once_with('foo', bar='baz')
>>> mock('other', bar='values')
>>> mock.assert_called_once_with('other', bar='values')
Traceback (most recent call last):
...
AssertionError: Expected 'mock' to be called once with arguments ('other', 'values')
```

`assert_any_call(*args, **kwargs)`

assert the mock has been called with the specified arguments.

The assert passes if the mock has *ever* been called, unlike `assert_called_with()` and `assert_called_once_with()` that only pass if the call is the most recent one, and in the case of `assert_called_once_with()` it must also be the only call.

```
>>> mock = Mock(return_value=None)
>>> mock(1, 2, arg='thing')
>>> mock('some', 'thing', 'else')
>>> mock.assert_any_call(1, 2, arg='thing')
```

`assert_has_calls(calls, any_order=False)`

assert the mock has been called with the specified calls. The `mock_calls` list is checked for the calls.

If `any_order` is false then the calls must be sequential. There can be extra calls before or after the specified calls.

If `any_order` is true then the calls can be in any order, but they must all appear in `mock_calls`.

```
>>> mock = Mock(return_value=None)
>>> mock(1)
>>> mock(2)
>>> mock(3)
>>> mock(4)
>>> calls = [call(2), call(3)]
>>> mock.assert_has_calls(calls)
>>> calls = [call(4), call(2), call(3)]
>>> mock.assert_has_calls(calls, any_order=True)
```

`assert_not_called()`

Assert the mock was never called.

```
>>> m = Mock()
>>> m.hello.assert_not_called()
>>> obj = m.hello()
>>> m.hello.assert_not_called()
Traceback (most recent call last):
...
AssertionError: Expected 'hello' to not have been called
```

*New in version 3.5.*

`reset_mock(*, return_value=False, side_effect=False)`

The `reset_mock` method resets all the call attributes on a mock object:

```
>>> mock = Mock(return_value=None)
>>> mock('hello')
>>> mock.called
True
>>> mock.reset_mock()
>>> mock.called
False
```

*Changed in version 3.6:* Added two keyword-only arguments to the `reset_mock` function.

This can be useful where you want to make a series of assertions that reuse the same object. Note that `reset_mock()` *doesn't* clear the return value, `side_effect` or any child attributes you have set using normal assignment by default. In case you want to reset `return_value` or `side_effect`, then pass the corresponding parameter as `True`. Child mocks and the return value mock (if any) are reset as well.

### Note

`return_value`, and `side_effect` are keyword-only arguments.

`mock_add_spec(spec, spec_set=False)`

Add a spec to a mock. *spec* can either be an object or a list of strings. Only attributes on the *spec* can be fetched as attributes from the mock.

If *spec\_set* is true then only attributes on the spec can be set.

`attach_mock(mock, attribute)`

Attach a mock as an attribute of this one, replacing its name and parent. Calls to the attached mock will be recorded in the `method_calls` and `mock_calls` attributes of this one.

`configure_mock(**kwargs)`

Set attributes on the mock through keyword arguments.

Attributes plus return values and side effects can be set on child mocks using standard dot notation and unpacking a dictionary in the method call:

```
>>> mock = Mock()
>>> attrs = {'method.return_value': 3, 'other.s
>>> mock.configure_mock(**attrs)
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
...
KeyError
```

The same thing can be achieved in the constructor call to mocks:

```
>>> attrs = {'method.return_value': 3, 'other.s
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
```

```
3
>>> mock.other()
Traceback (most recent call last):
...
KeyError
```

`configure_mock()` exists to make it easier to do configuration after the mock has been created.

## `_dir_()`

**Mock** objects limit the results of `dir(some_mock)` to useful results. For mocks with a *spec* this includes all the permitted attributes for the mock.

See [FILTER\\_DIR](#) for what this filtering does, and how to switch it off.

## `_get_child_mock(**kw)`

Create the child mocks for attributes and return value. By default child mocks will be the same type as the parent. Subclasses of **Mock** may want to override this to customize the way child mocks are made.

For non-callable mocks the callable variant will be used (rather than any custom subclass).

## `called`

A boolean representing whether or not the mock object has been called:

```
>>> mock = Mock(return_value=None)
>>> mock.called
False
>>> mock()
>>> mock.called
True
```

## `call_count`

An integer telling you how many times the mock object has been called:

```
>>> mock = Mock(return_value=None)
>>> mock.call_count
0
>>> mock()
>>> mock()
>>> mock.call_count
2
```

### `return_value`

Set this to configure the value returned by calling the mock:

```
>>> mock = Mock()
>>> mock.return_value = 'fish'
>>> mock()
'fish'
```

The default return value is a mock object and you can configure it in the normal way:

```
>>> mock = Mock()
>>> mock.return_value.attribute = sentinel.Attribute
>>> mock.return_value()
<Mock name='mock()' id='...'>
>>> mock.return_value.assert_called_with()
```

**`return_value`** can also be set in the constructor:

```
>>> mock = Mock(return_value=3)
>>> mock.return_value
3
>>> mock()
3
```

### `side_effect`

This can either be a function to be called when the

mock is called, an iterable or an exception (class or instance) to be raised.

If you pass in a function it will be called with same arguments as the mock and unless the function returns the **DEFAULT** singleton the call to the mock will then return whatever the function returns. If the function returns **DEFAULT** then the mock will return its normal value (from the **return\_value**).

If you pass in an iterable, it is used to retrieve an iterator which must yield a value on every call. This value can either be an exception instance to be raised, or a value to be returned from the call to the mock (**DEFAULT** handling is identical to the function case).

An example of a mock that raises an exception (to test exception handling of an API):

```
>>> mock = Mock()
>>> mock.side_effect = Exception('Boom!')
>>> mock()
Traceback (most recent call last):
...
Exception: Boom!
```

Using **side\_effect** to return a sequence of values:

```
>>> mock = Mock()
>>> mock.side_effect = [3, 2, 1]
>>> mock(), mock(), mock()
(3, 2, 1)
```

Using a callable:

```
>>> mock = Mock(return_value=3)
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> mock.side_effect = side_effect
>>> mock()
```

`side_effect` can be set in the constructor. Here's an example that adds one to the value the mock is called with and returns it:

```
>>> side_effect = lambda value: value + 1
>>> mock = Mock(side_effect=side_effect)
>>> mock(3)
4
>>> mock(-8)
-7
```

Setting `side_effect` to `None` clears it:

```
>>> m = Mock(side_effect=KeyError, return_value=1)
>>> m()
Traceback (most recent call last):
...
KeyError
>>> m.side_effect = None
>>> m()
3
```

## call\_args

This is either `None` (if the mock hasn't been called), or the arguments that the mock was last called with. This will be in the form of a tuple: the first member, which can also be accessed through the `args` property, is any ordered arguments the mock was called with (or an empty tuple) and the second member, which can also be accessed through the `kwargs` property, is any keyword arguments (or an empty dictionary).

```
>>> mock = Mock(return_value=None)
>>> print(mock.call_args)
None
>>> mock()
>>> mock.call_args
call()
```

```

>>> mock.call_args == ()
True
>>> mock(3, 4)
>>> mock.call_args
call(3, 4)
>>> mock.call_args == ((3, 4),)
True
>>> mock.call_args.args
(3, 4)
>>> mock.call_args.kwargs
{}
>>> mock(3, 4, 5, key='fish', next='w00t!')
>>> mock.call_args
call(3, 4, 5, key='fish', next='w00t!')
>>> mock.call_args.args
(3, 4, 5)
>>> mock.call_args.kwargs
{'key': 'fish', 'next': 'w00t!'}

```

**call\_args**, along with members of the lists **call\_args\_list**, **method\_calls** and **mock\_calls** are **call** objects. These are tuples, so they can be unpacked to get at the individual arguments and make more complex assertions. See [calls as tuples](#).

*Changed in version 3.8:* Added `args` and `kwargs` properties.

## call\_args\_list

This is a list of all the calls made to the mock object in sequence (so the length of the list is the number of times it has been called). Before any calls have been made it is an empty list. The **call** object can be used for conveniently constructing lists of calls to compare with **call\_args\_list**.

```

>>> mock = Mock(return_value=None)
>>> mock()

```

```
>>> mock(3, 4)
>>> mock(key='fish', next='w00t!')
>>> mock.call_args_list
[call(), call(3, 4), call(key='fish', next='w00t!')]
>>> expected = [(), ((3, 4),), ({'key': 'fish', 'next': 'w00t!'},)]
>>> mock.call_args_list == expected
True
```

Members of `call_args_list` are `call` objects. These can be unpacked as tuples to get at the individual arguments. See [calls as tuples](#).

## method\_calls

As well as tracking calls to themselves, mocks also track calls to methods and attributes, and *their* methods and attributes:

```
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.property.method.attribute()
<Mock name='mock.property.method.attribute()' id='...'>
>>> mock.method_calls
[call.method(), call.property.method.attribute()]
```

Members of `method_calls` are `call` objects. These can be unpacked as tuples to get at the individual arguments. See [calls as tuples](#).

## mock\_calls

`mock_calls` records *all* calls to the mock object, its methods, magic methods *and* return value mocks.

```
>>> mock = MagicMock()
>>> result = mock(1, 2, 3)
>>> mock.first(a=3)
<MagicMock name='mock.first()' id='...'>
>>> mock.second()
<MagicMock name='mock.second()' id='...'>
```

```
>>> int(mock)
1
>>> result(1)
<MagicMock name='mock()' id='...'>
>>> expected = [call(1, 2, 3), call.first(a=3),
... call.__int__(), call()(1)]
>>> mock.mock_calls == expected
True
```

Members of `mock_calls` are `call` objects. These can be unpacked as tuples to get at the individual arguments. See [calls as tuples](#).

### Note

The way `mock_calls` are recorded means that where nested calls are made, the parameters of ancestor calls are not recorded and so will always compare equal:

```
>>> mock = MagicMock()
>>> mock.top(a=3).bottom()
<MagicMock name='mock.top().bottom()' id='...'>
>>> mock.mock_calls
[call.top(a=3), call.top().bottom()]
>>> mock.mock_calls[-1] == call.top(a=-1).bottom()
True
```

### `__class__`

Normally the `__class__` attribute of an object will return its type. For a mock object with a `spec`, `__class__` returns the spec class instead. This allows mock objects to pass `isinstance()` tests for the object they are replacing / masquerading as:

```
>>> mock = Mock(spec=3)
>>> isinstance(mock, int)
True
```

`__class__` is assignable to, this allows a mock to pass an `isinstance()` check without forcing you to use a `spec`:

```
>>> mock = Mock()
>>> mock.__class__ = dict
>>> isinstance(mock, dict)
True
```

`class unittest.mock.NonCallableMock(spec=None, wraps=None, name=None, spec_set=None, **kwargs)`

A non-callable version of `Mock`. The constructor parameters have the same meaning of `Mock`, with the exception of `return_value` and `side_effect` which have no meaning on a non-callable mock.

Mock objects that use a class or an instance as a `spec` or `spec_set` are able to pass `isinstance()` tests:

```
>>> mock = Mock(spec=SomeClass)
>>> isinstance(mock, SomeClass)
True
>>> mock = Mock(spec_set=SomeClass())
>>> isinstance(mock, SomeClass)
True
```

The `Mock` classes have support for mocking magic methods. See [magic methods](#) for the full details.

The mock classes and the `patch()` decorators all take arbitrary keyword arguments for configuration. For the `patch()` decorators the keywords are passed to the constructor of the mock being created. The keyword arguments are for configuring attributes of the mock:

```
>>> m = MagicMock(attribute=3, other='fish')
>>> m.attribute
3
>>> m.other
```

```
'fish'
```

The return value and side effect of child mocks can be set in the same way, using dotted notation. As you can't use dotted names directly in a call you have to create a dictionary and unpack it using `**`:

```
>>> attrs = {'method.return_value': 3, 'other.side_effect': 3}
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
...
KeyError
```

A callable mock which was created with a *spec* (or a *spec\_set*) will introspect the specification object's signature when matching calls to the mock. Therefore, it can match the actual call's arguments regardless of whether they were passed positionally or by name:

```
>>> def f(a, b, c): pass
...
>>> mock = Mock(spec=f)
>>> mock(1, 2, c=3)
<Mock name='mock()' id='140161580456576'>
>>> mock.assert_called_with(1, 2, 3)
>>> mock.assert_called_with(a=1, b=2, c=3)
```

This applies to `assert_called_with()`, `assert_called_once_with()`, `assert_has_calls()` and `assert_any_call()`. When *Autospeccing*, it will also apply to method calls on the mock object.

*Changed in version 3.4:* Added signature introspection on specced and autospecced mock objects.

```
class unittest.mock.PropertyMock(*args, **kwargs)
```

A mock intended to be used as a property, or other descriptor, on a class. **PropertyMock** provides `__get__()` and `__set__()` methods so you can specify a return value when it is fetched.

Fetching a **PropertyMock** instance from an object calls the mock, with no args. Setting it calls the mock with the value being set.

```
>>> class Foo:
...     @property
...     def foo(self):
...         return 'something'
...     @foo.setter
...     def foo(self, value):
...         pass
...
>>> with patch('__main__.Foo.foo', new_callable=PropertyMock):
...     mock_foo.return_value = 'mockity-mock'
...     this_foo = Foo()
...     print(this_foo.foo)
...     this_foo.foo = 6
...
mockity-mock
>>> mock_foo.mock_calls
[call(), call(6)]
```

Because of the way mock attributes are stored you can't directly attach a **PropertyMock** to a mock object. Instead you can attach it to the mock type object:

```
>>> m = MagicMock()
>>> p = PropertyMock(return_value=3)
>>> type(m).foo = p
>>> m.foo
3
>>> p.assert_called_once_with()
```

*class unittest.mock.AsyncMock(spec=None, side\_effect=None,*

*return\_value = DEFAULT, wraps = None, name = None, spec\_set = None, unsafe = False, \*\*kwargs)*

An asynchronous version of **MagicMock**. The **AsyncMock** object will behave so the object is recognized as an async function, and the result of a call is an awaitable.

```
>>> mock = AsyncMock()
>>> asyncio.iscoroutinefunction(mock)
True
>>> inspect.isawaitable(mock())
True
```

The result of `mock()` is an async function which will have the outcome of `side_effect` or `return_value` after it has been awaited:

- if `side_effect` is a function, the async function will return the result of that function,
- if `side_effect` is an exception, the async function will raise the exception,
- if `side_effect` is an iterable, the async function will return the next value of the iterable, however, if the sequence of result is exhausted, `StopAsyncIteration` is raised immediately,
- if `side_effect` is not defined, the async function will return the value defined by `return_value`, hence, by default, the async function returns a new **AsyncMock** object.

Setting the *spec* of a **Mock** or **MagicMock** to an async function will result in a coroutine object being returned after calling.

```
>>> async def async_func(): pass
...
>>> mock = MagicMock(async_func)
>>> mock
<MagicMock spec='function' id='...'>
>>> mock()
<coroutine object AsyncMockMixin._mock_call at ...>
```

Setting the *spec* of a **Mock**, **MagicMock**, or **AsyncMock** to a class with asynchronous and synchronous functions will automatically detect the synchronous functions and set them as **MagicMock** (if the parent mock is **AsyncMock** or **MagicMock**) or **Mock** (if the parent mock is **Mock**). All asynchronous functions will be **AsyncMock**.

```
>>> class ExampleClass:
...     def sync_foo():
...         pass
...     async def async_foo():
...         pass
...
>>> a_mock = AsyncMock(ExampleClass)
>>> a_mock.sync_foo
<MagicMock name='mock.sync_foo' id='...'>
>>> a_mock.async_foo
<AsyncMock name='mock.async_foo' id='...'>
>>> mock = Mock(ExampleClass)
>>> mock.sync_foo
<Mock name='mock.sync_foo' id='...'>
>>> mock.async_foo
<AsyncMock name='mock.async_foo' id='...'>
```

*New in version 3.8.*

**assert\_awaited()**

Assert that the mock was awaited at least once. Note that this is separate from the object having been called, the `await` keyword must be used:

```
>>> mock = AsyncMock()
>>> async def main(coroutine_mock):
...     await coroutine_mock
...
>>> coroutine_mock = mock()
>>> mock.called
True
>>> mock.assert_awaited()
```

```
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awaited
>>> asyncio.run(main(coroutine_mock))
>>> mock.assert_awaited()
```

### `assert_awaited_once()`

Assert that the mock was awaited exactly once.

```
>>> mock = AsyncMock()
>>> async def main():
...     await mock()
...
>>> asyncio.run(main())
>>> mock.assert_awaited_once()
>>> asyncio.run(main())
>>> mock.method.assert_awaited_once()
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awaited once
```

### `assert_awaited_with(*args, **kwargs)`

Assert that the last await was with the specified arguments.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_with('foo', bar='bar')
>>> mock.assert_awaited_with('other')
Traceback (most recent call last):
...
AssertionError: expected call not found.
Expected: mock('other')
Actual: mock('foo', bar='bar')
```

### `assert_awaited_once_with(*args, **kwargs)`

Assert that the mock was awaited exactly once and with the specified arguments.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_once_with('foo', bar='bar')
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_once_with('foo', bar='bar')
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awaited once with the specified arguments
```

### `assert_any_await(*args, **kwargs)`

Assert the mock has ever been awaited with the specified arguments.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> asyncio.run(main('hello'))
>>> mock.assert_any_await('foo', bar='bar')
>>> mock.assert_any_await('other')
Traceback (most recent call last):
...
AssertionError: mock('other') await not found
```

### `assert_has_awaits(calls, any_order=False)`

Assert the mock has been awaited with the specified calls. The `await_args_list` list is checked for the awaits.

If `any_order` is false then the awaits must be sequential.

There can be extra calls before or after the specified awaits.

If *any\_order* is true then the awaits can be in any order, but they must all appear in `await_args_list`.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> calls = [call("foo"), call("bar")]
>>> mock.assert_has_awaits(calls)
Traceback (most recent call last):
...
AssertionError: Awaits not found.
Expected: [call('foo'), call('bar')]
Actual: []
>>> asyncio.run(main('foo'))
>>> asyncio.run(main('bar'))
>>> mock.assert_has_awaits(calls)
```

### `assert_not_awaited()`

Assert that the mock was never awaited.

```
>>> mock = AsyncMock()
>>> mock.assert_not_awaited()
```

### `reset_mock(*args, **kwargs)`

See `Mock.reset_mock()`. Also sets `await_count` to 0, `await_args` to None, and clears the `await_args_list`.

### `await_count`

An integer keeping track of how many times the mock object has been awaited.

```
>>> mock = AsyncMock()
>>> async def main():
```

```

...     await mock()
...
>>> asyncio.run(main())
>>> mock.await_count
1
>>> asyncio.run(main())
>>> mock.await_count
2

```

### await\_args

This is either `None` (if the mock hasn't been awaited), or the arguments that the mock was last awaited with. Functions the same as [Mock.call\\_args](#).

```

>>> mock = AsyncMock()
>>> async def main(*args):
...     await mock(*args)
...
>>> mock.await_args
>>> asyncio.run(main('foo'))
>>> mock.await_args
call('foo')
>>> asyncio.run(main('bar'))
>>> mock.await_args
call('bar')

```

### await\_args\_list

This is a list of all the awaits made to the mock object in sequence (so the length of the list is the number of times it has been awaited). Before any awaits have been made it is an empty list.

```

>>> mock = AsyncMock()
>>> async def main(*args):
...     await mock(*args)
...
>>> mock.await_args_list
[]

```

```
>>> asyncio.run(main('foo'))
>>> mock.await_args_list
[call('foo')]
>>> asyncio.run(main('bar'))
>>> mock.await_args_list
[call('foo'), call('bar')]
```

## Calling

Mock objects are callable. The call will return the value set as the **return\_value** attribute. The default return value is a new Mock object; it is created the first time the return value is accessed (either explicitly or by calling the Mock) - but it is stored and the same one returned each time.

Calls made to the object will be recorded in the attributes like **call\_args** and **call\_args\_list**.

If **side\_effect** is set then it will be called after the call has been recorded, so if **side\_effect** raises an exception the call is still recorded.

The simplest way to make a mock raise an exception when called is to make **side\_effect** an exception class or instance:

```
>>> m = MagicMock(side_effect=IndexError)
>>> m(1, 2, 3)
Traceback (most recent call last):
...
IndexError
>>> m.mock_calls
[call(1, 2, 3)]
>>> m.side_effect = KeyError('Bang!')
>>> m('two', 'three', 'four')
Traceback (most recent call last):
...
KeyError: 'Bang!'
>>> m.mock_calls
[call(1, 2, 3), call('two', 'three', 'four')]
```

If **side\_effect** is a function then whatever that function returns is what calls to the mock return. The **side\_effect** function is called with the same arguments as the mock. This allows you to vary the return value of the call dynamically, based on the input:

```
>>> def side_effect(value):
...     return value + 1
...
>>> m = MagicMock(side_effect=side_effect)
>>> m(1)
2
>>> m(2)
3
>>> m.mock_calls
[call(1), call(2)]
```

If you want the mock to still return the default return value (a new mock), or any set return value, then there are two ways of doing this. Either return **mock.return\_value** from inside **side\_effect**, or return **DEFAULT**:

```
>>> m = MagicMock()
>>> def side_effect(*args, **kwargs):
...     return m.return_value
...
>>> m.side_effect = side_effect
>>> m.return_value = 3
>>> m()
3
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> m.side_effect = side_effect
>>> m()
3
```

To remove a **side\_effect**, and return to the default behaviour, set the **side\_effect** to **None**:

```
>>> m = MagicMock(return_value=6)
```

```

>>> def side_effect(*args, **kwargs):
...     return 3
...
>>> m.side_effect = side_effect
>>> m()
3
>>> m.side_effect = None
>>> m()
6

```

The **side\_effect** can also be any iterable object. Repeated calls to the mock will return values from the iterable (until the iterable is exhausted and a **StopIteration** is raised):

```

>>> m = MagicMock(side_effect=[1, 2, 3])
>>> m()
1
>>> m()
2
>>> m()
3
>>> m()
Traceback (most recent call last):
...
StopIteration

```

If any members of the iterable are exceptions they will be raised instead of returned:

```

>>> iterable = (33, ValueError, 66)
>>> m = MagicMock(side_effect=iterable)
>>> m()
33
>>> m()
Traceback (most recent call last):
...
ValueError
>>> m()
66

```

## Deleting Attributes

Mock objects create attributes on demand. This allows them to pretend to be objects of any type.

You may want a mock object to return `False` to a `hasattr()` call, or raise an `AttributeError` when an attribute is fetched. You can do this by providing an object as a `spec` for a mock, but that isn't always convenient.

You “block” attributes by deleting them. Once deleted, accessing an attribute will raise an `AttributeError`.

```
>>> mock = MagicMock()
>>> hasattr(mock, 'm')
True
>>> del mock.m
>>> hasattr(mock, 'm')
False
>>> del mock.f
>>> mock.f
Traceback (most recent call last):
...
AttributeError: f
```

## Mock names and the name attribute

Since “name” is an argument to the `Mock` constructor, if you want your mock object to have a “name” attribute you can't just pass it in at creation time. There are two alternatives. One option is to use `configure_mock()`:

```
>>> mock = MagicMock()
>>> mock.configure_mock(name='my_name')
>>> mock.name
'my_name'
```

A simpler option is to simply set the “name” attribute after mock creation:

```
>>> mock = MagicMock()
>>> mock.name = "foo"
```

## Attaching Mocks as Attributes

When you attach a mock as an attribute of another mock (or as the return value) it becomes a “child” of that mock. Calls to the child are recorded in the `method_calls` and `mock_calls` attributes of the parent. This is useful for configuring child mocks and then attaching them to the parent, or for attaching mocks to a parent that records all calls to the children and allows you to make assertions about the order of calls between mocks:

```
>>> parent = MagicMock()
>>> child1 = MagicMock(return_value=None)
>>> child2 = MagicMock(return_value=None)
>>> parent.child1 = child1
>>> parent.child2 = child2
>>> child1(1)
>>> child2(2)
>>> parent.mock_calls
[call.child1(1), call.child2(2)]
```

The exception to this is if the mock has a name. This allows you to prevent the “parenting” if for some reason you don’t want it to happen.

```
>>> mock = MagicMock()
>>> not_a_child = MagicMock(name='not-a-child')
>>> mock.attribute = not_a_child
>>> mock.attribute()
<MagicMock name='not-a-child()' id='... '>
>>> mock.mock_calls
[]
```

Mocks created for you by `patch()` are automatically given names. To attach mocks that have names to a parent you use the `attach_mock()` method:

```
>>> thing1 = object()
```

```
>>> thing2 = object()
>>> parent = MagicMock()
>>> with patch('__main__.thing1', return_value=None) as
...     with patch('__main__.thing2', return_value=None)
...         parent.attach_mock(child1, 'child1')
...         parent.attach_mock(child2, 'child2')
...         child1('one')
...         child2('two')
...
>>> parent.mock_calls
[call.child1('one'), call.child2('two')]
```

1

The only exceptions are magic methods and attributes (those that have leading and trailing double underscores). Mock doesn't create these but instead raises an [AttributeError](#). This is because the interpreter will often implicitly request these methods, and gets *very* confused to get a new Mock object when it expects a magic method. If you need magic method support see [magic methods](#).

## The patchers

The patch decorators are used for patching objects only within the scope of the function they decorate. They automatically handle the unpatching for you, even if exceptions are raised. All of these functions can also be used in with statements or as class decorators.

### patch

#### Note

The key is to do the patching in the right namespace. See the section [where to patch](#).

```
unittest.mock.patch(target, new=DEFAULT, spec=None,
create=False, spec_set=None, autospec=None, new_callable=None,
**kwargs)
```

`patch()` acts as a function decorator, class decorator or a context manager. Inside the body of the function or with statement, the *target* is patched with a *new* object. When the function/with statement exits the patch is undone.

If *new* is omitted, then the target is replaced with an **AsyncMock** if the patched object is an async function or a **MagicMock** otherwise. If `patch()` is used as a decorator and *new* is omitted, the created mock is passed in as an extra argument to the decorated function. If `patch()` is used as a context manager the created mock is returned by the context manager.

*target* should be a string in the form `'package.module.ClassName'`. The *target* is imported and the specified object replaced with the *new* object, so the *target* must be importable from the environment you are calling `patch()` from. The target is imported when the decorated function is executed, not at decoration time.

The *spec* and *spec\_set* keyword arguments are passed to the **MagicMock** if patch is creating one for you.

In addition you can pass `spec=True` or `spec_set=True`, which causes patch to pass in the object being mocked as the *spec/spec\_set* object.

*new\_callable* allows you to specify a different class, or callable object, that will be called to create the *new* object. By default **AsyncMock** is used for async functions and **MagicMock** for the rest.

A more powerful form of *spec* is *autospec*. If you set `autospec=True` then the mock will be created with a *spec* from the object being replaced. All attributes of the mock will also have the *spec* of the corresponding attribute of the object being replaced. Methods and functions being mocked will have their arguments checked and will raise a **TypeError** if they are called with the wrong signature. For mocks replacing a class, their return value (the ‘instance’) will have the same *spec* as the class. See the `create_autospec()` function

and [Autospeccing](#).

Instead of `autospec=True` you can pass `autospec=some_object` to use an arbitrary object as the spec instead of the one being replaced.

By default `patch()` will fail to replace attributes that don't exist. If you pass in `create=True`, and the attribute doesn't exist, patch will create the attribute for you when the patched function is called, and delete it again after the patched function has exited. This is useful for writing tests against attributes that your production code creates at runtime. It is off by default because it can be dangerous. With it switched on you can write passing tests against APIs that don't actually exist!

### Note

*Changed in version 3.5:* If you are patching builtins in a module then you don't need to pass `create=True`, it will be added by default.

Patch can be used as a **TestCase** class decorator. It works by decorating each test method in the class. This reduces the boilerplate code when your test methods share a common patchings set. `patch()` finds tests by looking for method names that start with `patch.TEST_PREFIX`. By default this is `'test '`, which matches the way [unittest](#) finds tests. You can specify an alternative prefix by setting `patch.TEST_PREFIX`.

Patch can be used as a context manager, with the `with` statement. Here the patching applies to the indented block after the `with` statement. If you use `“as”` then the patched object will be bound to the name after the `“as”`; very useful if `patch()` is creating a mock object for you.

`patch()` takes arbitrary keyword arguments. These will be passed to [AsyncMock](#) if the patched object is asynchronous, to [MagicMock](#) otherwise or to `new_callable` if specified.

`patch.dict(...)`, `patch.multiple(...)` and `patch.object(...)` are available for alternate use-cases.

**`patch()`** as function decorator, creating the mock for you and passing it into the decorated function:

```
>>> @patch('__main__.SomeClass')
... def function(normal_argument, mock_class):
...     print(mock_class is SomeClass)
...
>>> function(None)
True
```

Patching a class replaces the class with a **MagicMock** instance. If the class is instantiated in the code under test then it will be the **return\_value** of the mock that will be used.

If the class is instantiated multiple times you could use **side\_effect** to return a new mock each time. Alternatively you can set the *return\_value* to be anything you want.

To configure return values on methods of *instances* on the patched class you must do this on the **return\_value**. For example:

```
>>> class Class:
...     def method(self):
...         pass
...
>>> with patch('__main__.Class') as MockClass:
...     instance = MockClass.return_value
...     instance.method.return_value = 'foo'
...     assert Class() is instance
...     assert Class().method() == 'foo'
... 
```

If you use *spec* or *spec.set* and **`patch()`** is replacing a *class*, then the return value of the created mock will have the same spec.

```
>>> Original = Class
>>> patcher = patch('__main__.Class', spec=True)
```

```
>>> MockClass = patcher.start()
>>> instance = MockClass()
>>> assert isinstance(instance, Original)
>>> patcher.stop()
```

The *new\_callable* argument is useful where you want to use an alternative class to the default **MagicMock** for the created mock. For example, if you wanted a **NonCallableMock** to be used:

```
>>> thing = object()
>>> with patch('__main__.thing', new_callable=NonCallableMock):
...     assert thing is mock_thing
...     thing()
...
Traceback (most recent call last):
...
TypeError: 'NonCallableMock' object is not callable
```

Another use case might be to replace an object with an **io.StringIO** instance:

```
>>> from io import StringIO
>>> def foo():
...     print('Something')
...
>>> @patch('sys.stdout', new_callable=StringIO)
... def test(mock_stdout):
...     foo()
...     assert mock_stdout.getvalue() == 'Something\n'
...
>>> test()
```

When **patch()** is creating a mock for you, it is common that the first thing you need to do is to configure the mock. Some of that configuration can be done in the call to patch. Any arbitrary keywords you pass into the call will be used to set attributes on the created mock:

```
>>> patcher = patch('__main__.thing', first='one', second='two')
>>> mock_thing = patcher.start()
```

```
>>> mock_thing.first
'one'
>>> mock_thing.second
'two'
```

As well as attributes on the created mock attributes, like the **return\_value** and **side\_effect**, of child mocks can also be configured. These aren't syntactically valid to pass in directly as keyword arguments, but a dictionary with these as keys can still be expanded into a **patch()** call using **\*\***:

```
>>> config = {'method.return_value': 3, 'other.side_effect': 42}
>>> patcher = patch('__main__.thing', **config)
>>> mock_thing = patcher.start()
>>> mock_thing.method()
3
>>> mock_thing.other()
Traceback (most recent call last):
...
KeyError
```

By default, attempting to patch a function in a module (or a method or an attribute in a class) that does not exist will fail with **AttributeError**:

```
>>> @patch('sys.non_existing_attribute', 42)
... def test():
...     assert sys.non_existing_attribute == 42
...
>>> test()
Traceback (most recent call last):
...
AttributeError: <module 'sys' (built-in)> does not have
```

but adding **create=True** in the call to **patch()** will make the previous example work as expected:

```
>>> @patch('sys.non_existing_attribute', 42, create=True)
... def test(mock_stdout):
...     assert sys.non_existing_attribute == 42
```

```
...
>>> test()
```

Changed in version 3.8: `patch()` now returns an `AsyncMock` if the target is an async function.

## patch.object

`patch.object(target, attribute, new=DEFAULT, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)`

patch the named member (*attribute*) on an object (*target*) with a mock object.

`patch.object()` can be used as a decorator, class decorator or a context manager. Arguments *new*, *spec*, *create*, *spec\_set*, *autospec* and *new\_callable* have the same meaning as for `patch()`. Like `patch()`, `patch.object()` takes arbitrary keyword arguments for configuring the mock object it creates.

When used as a class decorator `patch.object()` honours `patch.TEST_PREFIX` for choosing which methods to wrap.

You can either call `patch.object()` with three arguments or two arguments. The three argument form takes the object to be patched, the attribute name and the object to replace the attribute with.

When calling with the two argument form you omit the replacement object, and a mock is created for you and passed in as an extra argument to the decorated function:

```
>>> @patch.object(SomeClass, 'class_method')
... def test(mock_method):
...     SomeClass.class_method(3)
...     mock_method.assert_called_with(3)
...
>>> test()
```

*spec*, *create* and the other arguments to `patch.object()` have the

same meaning as they do for `patch()`.

## **patch.dict**

`patch.dict(in_dict, values=(), clear=False, **kwargs)`

Patch a dictionary, or dictionary like object, and restore the dictionary to its original state after the test.

*in\_dict* can be a dictionary or a mapping like container. If it is a mapping then it must at least support getting, setting and deleting items plus iterating over keys.

*in\_dict* can also be a string specifying the name of the dictionary, which will then be fetched by importing it.

*values* can be a dictionary of values to set in the dictionary. *values* can also be an iterable of (key, value) pairs.

If *clear* is true then the dictionary will be cleared before the new values are set.

`patch.dict()` can also be called with arbitrary keyword arguments to set values in the dictionary.

*Changed in version 3.8:* `patch.dict()` now returns the patched dictionary when used as a context manager.

`patch.dict()` can be used as a context manager, decorator or class decorator:

```
>>> foo = {}
>>> @patch.dict(foo, {'newkey': 'newvalue'})
... def test():
...     assert foo == {'newkey': 'newvalue'}
...
>>> test()
>>> assert foo == {}
```

When used as a class decorator `patch.dict()` honours `patch.TEST_PREFIX` (default to 'test') for choosing which

methods to wrap:

```
>>> import os
>>> import unittest
>>> from unittest.mock import patch
>>> @patch.dict('os.environ', {'newkey': 'newvalue'})
... class TestSample(unittest.TestCase):
...     def test_sample(self):
...         self.assertEqual(os.environ['newkey'], 'newvalue')
```

If you want to use a different prefix for your test, you can inform the patchers of the different prefix by setting `patch.TEST_PREFIX`. For more details about how to change the value of see [TEST\\_PREFIX](#).

**`patch.dict()`** can be used to add members to a dictionary, or simply let a test change a dictionary, and ensure the dictionary is restored when the test ends.

```
>>> foo = {}
>>> with patch.dict(foo, {'newkey': 'newvalue'}) as patched_foo:
...     assert foo == {'newkey': 'newvalue'}
...     assert patched_foo == {'newkey': 'newvalue'}
...     # You can add, update or delete keys of foo (or patched_foo)
...     patched_foo['spam'] = 'eggs'
...
>>> assert foo == {}
>>> assert patched_foo == {}

>>> import os
>>> with patch.dict('os.environ', {'newkey': 'newvalue'}) as patched_os_environ:
...     print(os.environ['newkey'])
...
newvalue
>>> assert 'newkey' not in os.environ
```

Keywords can be used in the **`patch.dict()`** call to set values in the dictionary:

```
>>> mymodule = MagicMock()
```

```
>>> mymodule.function.return_value = 'fish'
>>> with patch.dict('sys.modules', mymodule=mymodule):
...     import mymodule
...     mymodule.function('some', 'args')
...
'fish'
```

**patch.dict()** can be used with dictionary like objects that aren't actually dictionaries. At the very minimum they must support item getting, setting, deleting and either iteration or membership test. This corresponds to the magic methods **\_\_getitem\_\_()**, **\_\_setitem\_\_()**, **\_\_delitem\_\_()** and either **\_\_iter\_\_()** or **\_\_contains\_\_()**.

```
>>> class Container:
...     def __init__(self):
...         self.values = {}
...     def __getitem__(self, name):
...         return self.values[name]
...     def __setitem__(self, name, value):
...         self.values[name] = value
...     def __delitem__(self, name):
...         del self.values[name]
...     def __iter__(self):
...         return iter(self.values)
...
>>> thing = Container()
>>> thing['one'] = 1
>>> with patch.dict(thing, one=2, two=3):
...     assert thing['one'] == 2
...     assert thing['two'] == 3
...
>>> assert thing['one'] == 1
>>> assert list(thing) == ['one']
```

## patch.multiple

**patch.multiple(target, spec=None, create=False, spec\_set=None, autospec=None, new\_callable=None, \*\*kwargs)**

Perform multiple patches in a single call. It takes the object to be patched (either as an object or a string to fetch the object by importing) and keyword arguments for the patches:

```
with patch.multiple(settings, FIRST_PATCH='one', SECOND_PATCH='two',
    ...
```

Use **DEFAULT** as the value if you want `patch.multiple()` to create mocks for you. In this case the created mocks are passed into a decorated function by keyword, and a dictionary is returned when `patch.multiple()` is used as a context manager.

`patch.multiple()` can be used as a decorator, class decorator or a context manager. The arguments *spec*, *spec\_set*, *create*, *autospec* and *new\_callable* have the same meaning as for `patch()`. These arguments will be applied to *all* patches done by `patch.multiple()`.

When used as a class decorator `patch.multiple()` honours `patch.TEST_PREFIX` for choosing which methods to wrap.

If you want `patch.multiple()` to create mocks for you, then you can use **DEFAULT** as the value. If you use `patch.multiple()` as a decorator then the created mocks are passed into the decorated function by keyword.

```
>>> thing = object()
>>> other = object()

>>> @patch.multiple('__main__', thing=DEFAULT, other=DEFAULT)
... def test_function(thing, other):
...     assert isinstance(thing, MagicMock)
...     assert isinstance(other, MagicMock)
...
>>> test_function()
```

`patch.multiple()` can be nested with other `patch` decorators, but put arguments passed by keyword *after* any of the standard

arguments created by `patch()`:

```
>>> @patch('sys.exit')
... @patch.multiple('__main__', thing=DEFAULT, other=DEF
... def test_function(mock_exit, other, thing):
...     assert 'other' in repr(other)
...     assert 'thing' in repr(thing)
...     assert 'exit' in repr(mock_exit)
...
>>> test_function()
```

If `patch.multiple()` is used as a context manager, the value returned by the context manager is a dictionary where created mocks are keyed by name:

```
>>> with patch.multiple('__main__', thing=DEFAULT, other
...     assert 'other' in repr(values['other'])
...     assert 'thing' in repr(values['thing'])
...     assert values['thing'] is thing
...     assert values['other'] is other
...
```

## patch methods: start and stop

All the patchers have `start()` and `stop()` methods. These make it simpler to do patching in `setUp` methods or where you want to do multiple patches without nesting decorators or with statements.

To use them call `patch()`, `patch.object()` or `patch.dict()` as normal and keep a reference to the returned patcher object. You can then call `start()` to put the patch in place and `stop()` to undo it.

If you are using `patch()` to create a mock for you then it will be returned by the call to `patcher.start`.

```
>>> patcher = patch('package.module.ClassName')
>>> from package import module
>>> original = module.ClassName
>>> new_mock = patcher.start()
```

```
>>> assert module.ClassName is not original
>>> assert module.ClassName is new_mock
>>> patcher.stop()
>>> assert module.ClassName is original
>>> assert module.ClassName is not new_mock
```

A typical use case for this might be for doing multiple patches in the `setUp` method of a **TestCase**:

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         self.patcher1 = patch('package.module.Class1')
...         self.patcher2 = patch('package.module.Class2')
...         self.MockClass1 = self.patcher1.start()
...         self.MockClass2 = self.patcher2.start()
...
...     def tearDown(self):
...         self.patcher1.stop()
...         self.patcher2.stop()
...
...     def test_something(self):
...         assert package.module.Class1 is self.MockClass1
...         assert package.module.Class2 is self.MockClass2
...
>>> MyTest('test_something').run()
```

## Caution

If you use this technique you must ensure that the patching is “undone” by calling `stop`. This can be fiddlier than you might think, because if an exception is raised in the `setUp` then `tearDown` is not called.

**`unittest.TestCase.addCleanup()`** makes this easier:

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         patcher = patch('package.module.Class')
...         self.MockClass = patcher.start()
...         self.addCleanup(patcher.stop)
```

```
...
...     def test_something(self):
...         assert package.module.Class is self.MockClass
...
```

As an added bonus you no longer need to keep a reference to the patcher object.

It is also possible to stop all patches which have been started by using `patch.stopall()`.

`patch.stopall()`

Stop all active patches. Only stops patches started with `start`.

## patch builtins

You can patch any builtins within a module. The following example patches builtin `ord()`:

```
>>> @patch('__main__.ord')
... def test(mock_ord):
...     mock_ord.return_value = 101
...     print(ord('c'))
...
>>> test()
101
```

## TEST\_PREFIX

All of the patchers can be used as class decorators. When used in this way they wrap every test method on the class. The patchers recognise methods that start with `'test'` as being test methods. This is the same way that the `unittest.TestLoader` finds test methods by default.

It is possible that you want to use a different prefix for your tests. You can inform the patchers of the different prefix by setting `patch.TEST_PREFIX`:

```

>>> patch.TEST_PREFIX = 'foo'
>>> value = 3
>>>
>>> @patch('__main__.value', 'not three')
... class Thing:
...     def foo_one(self):
...         print(value)
...     def foo_two(self):
...         print(value)
...
>>>
>>> Thing().foo_one()
not three
>>> Thing().foo_two()
not three
>>> value
3

```

## Nesting Patch Decorators

If you want to perform multiple patches then you can simply stack up the decorators.

You can stack up multiple patch decorators using this pattern:

```

>>> @patch.object(SomeClass, 'class_method')
... @patch.object(SomeClass, 'static_method')
... def test(mock1, mock2):
...     assert SomeClass.static_method is mock1
...     assert SomeClass.class_method is mock2
...     SomeClass.static_method('foo')
...     SomeClass.class_method('bar')
...     return mock1, mock2
...
>>> mock1, mock2 = test()
>>> mock1.assert_called_once_with('foo')
>>> mock2.assert_called_once_with('bar')

```

Note that the decorators are applied from the bottom upwards. This

is the standard way that Python applies decorators. The order of the created mocks passed into your test function matches this order.

## Where to patch

`patch()` works by (temporarily) changing the object that a *name* points to with another one. There can be many names pointing to any individual object, so for patching to work you must ensure that you patch the name used by the system under test.

The basic principle is that you patch where an object is *looked up*, which is not necessarily the same place as where it is defined. A couple of examples will help to clarify this.

Imagine we have a project that we want to test with the following structure:

```
a.py
    -> Defines SomeClass
```

```
b.py
    -> from a import SomeClass
    -> some_function instantiates SomeClass
```

Now we want to test `some_function` but we want to mock out `SomeClass` using `patch()`. The problem is that when we import module `b`, which we will have to do then it imports `SomeClass` from module `a`. If we use `patch()` to mock out `a.SomeClass` then it will have no effect on our test; module `b` already has a reference to the *real* `SomeClass` and it looks like our patching had no effect.

The key is to patch out `SomeClass` where it is used (or where it is looked up). In this case `some_function` will actually look up `SomeClass` in module `b`, where we have imported it. The patching should look like:

```
@patch('b.SomeClass')
```

However, consider the alternative scenario where instead of `from a import SomeClass` module `b` does `import a` and

`some_function` uses `a.SomeClass`. Both of these import forms are common. In this case the class we want to patch is being looked up in the module and so we have to patch `a.SomeClass` instead:

```
@patch('a.SomeClass')
```

## Patching Descriptors and Proxy Objects

Both [patch](#) and [patch.object](#) correctly patch and restore descriptors: class methods, static methods and properties. You should patch these on the *class* rather than an instance. They also work with *some* objects that proxy attribute access, like the [django settings object](#) [[https://web.archive.org/web/20200603181648/http://www.voidspace.org.uk/python/weblog/arch\\_d7\\_2010\\_12\\_04.shtml#e1198](https://web.archive.org/web/20200603181648/http://www.voidspace.org.uk/python/weblog/arch_d7_2010_12_04.shtml#e1198)].

## MagicMock and magic method support

### Mocking Magic Methods

[Mock](#) supports mocking the Python protocol methods, also known as “magic methods”. This allows mock objects to replace containers or other objects that implement Python protocols.

Because magic methods are looked up differently from normal methods [2](#), this support has been specially implemented. This means that only specific magic methods are supported. The supported list includes *almost* all of them. If there are any missing that you need please let us know.

You mock magic methods by setting the method you are interested in to a function or a mock instance. If you are using a function then it *must* take `self` as the first argument [3](#).

```
>>> def __str__(self):
...     return 'fooble'
...
>>> mock = Mock()
>>> mock.__str__ = __str__
>>> str(mock)
'fooble'
```

```
>>> mock = Mock()
>>> mock.__str__ = Mock()
>>> mock.__str__.return_value = 'fooble'
>>> str(mock)
'fooble'

>>> mock = Mock()
>>> mock.__iter__ = Mock(return_value=iter([]))
>>> list(mock)
[]
```

One use case for this is for mocking objects used as context managers in a **with** statement:

```
>>> mock = Mock()
>>> mock.__enter__ = Mock(return_value='foo')
>>> mock.__exit__ = Mock(return_value=False)
>>> with mock as m:
...     assert m == 'foo'
...
>>> mock.__enter__.assert_called_with()
>>> mock.__exit__.assert_called_with(None, None, None)
```

Calls to magic methods do not appear in **method\_calls**, but they are recorded in **mock\_calls**.

## Note

If you use the *spec* keyword argument to create a mock then attempting to set a magic method that isn't in the spec will raise an **AttributeError**.

The full list of supported magic methods is:

- `__hash__`, `__sizeof__`, `__repr__` and `__str__`
- `__dir__`, `__format__` and `__subclasses__`
- `__round__`, `__floor__`, `__trunc__` and `__ceil__`
- Comparisons: `__lt__`, `__gt__`, `__le__`, `__ge__`, `__eq__` and `__ne__`
- Container methods: `__getitem__`, `__setitem__`,

- `__delitem__`, `__contains__`, `__len__`, `__iter__`, `__reversed__` and `__missing__`
- Context manager: `__enter__`, `__exit__`, `__aenter__` and `__aexit__`
- Unary numeric methods: `__neg__`, `__pos__` and `__invert__`
- The numeric methods (including right hand and in-place variants): `__add__`, `__sub__`, `__mul__`, `__matmul__`, `__truediv__`, `__floordiv__`, `__mod__`, `__divmod__`, `__lshift__`, `__rshift__`, `__and__`, `__xor__`, `__or__`, and `__pow__`
- Numeric conversion methods: `__complex__`, `__int__`, `__float__` and `__index__`
- Descriptor methods: `__get__`, `__set__` and `__delete__`
- Pickling: `__reduce__`, `__reduce_ex__`, `__getinitargs__`, `__getnewargs__`, `__getstate__` and `__setstate__`
- File system path representation: `__fspath__`
- Asynchronous iteration methods: `__aiter__` and `__anext__`

*Changed in version 3.8:* Added support for `os.PathLike.__fspath__()`.

*Changed in version 3.8:* Added support for `__aenter__`, `__aexit__`, `__aiter__` and `__anext__`.

The following methods exist but are *not* supported as they are either in use by mock, can't be set dynamically, or can cause problems:

- `__getattr__`, `__setattr__`, `__init__` and `__new__`
- `__prepare__`, `__instancecheck__`, `__subclasscheck__`, `__del__`

## Magic Mock

There are two MagicMock variants: **MagicMock** and **NonCallableMagicMock**.

```
class unittest.mock.MagicMock(*args, **kw)
```

`MagicMock` is a subclass of `Mock` with default implementations of most of the magic methods. You can use `MagicMock` without having to configure the magic methods yourself.

The constructor parameters have the same meaning as for `Mock`.

If you use the `spec` or `spec_set` arguments then *only* magic methods that exist in the spec will be created.

```
class unittest.mock.NonCallableMagicMock(*args, **kw)
```

A non-callable version of `MagicMock`.

The constructor parameters have the same meaning as for `MagicMock`, with the exception of `return_value` and `side_effect` which have no meaning on a non-callable mock.

The magic methods are setup with `MagicMock` objects, so you can configure them and use them in the usual way:

```
>>> mock = MagicMock()
>>> mock[3] = 'fish'
>>> mock.__setitem__.assert_called_with(3, 'fish')
>>> mock.__getitem__.return_value = 'result'
>>> mock[2]
'result'
```

By default many of the protocol methods are required to return objects of a specific type. These methods are preconfigured with a default return value, so that they can be used without you having to do anything if you aren't interested in the return value. You can still *set* the return value manually if you want to change the default.

Methods and their defaults:

- `__lt__`: `NotImplemented`
- `__gt__`: `NotImplemented`
- `__le__`: `NotImplemented`
- `__ge__`: `NotImplemented`

- `__int__`: 1
- `__contains__`: False
- `__len__`: 0
- `__iter__`: `iter([])`
- `__exit__`: False
- `__aexit__`: False
- `__complex__`: `1j`
- `__float__`: `1.0`
- `__bool__`: True
- `__index__`: 1
- `__hash__`: default hash for the mock
- `__str__`: default str for the mock
- `__sizeof__`: default sizeof for the mock

For example:

```
>>> mock = MagicMock()
>>> int(mock)
1
>>> len(mock)
0
>>> list(mock)
[]
>>> object() in mock
False
```

The two equality methods, `__eq__()` and `__ne__()`, are special. They do the default equality comparison on identity, using the [side\\_effect](#) attribute, unless you change their return value to return something else:

```
>>> MagicMock() == 3
False
>>> MagicMock() != 3
True
>>> mock = MagicMock()
>>> mock.__eq__.return_value = True
>>> mock == 3
True
```

The return value of **MagicMock.\_\_iter\_\_()** can be any iterable object and isn't required to be an iterator:

```
>>> mock = MagicMock()
>>> mock.__iter__.return_value = ['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
```

If the return value *is* an iterator, then iterating over it once will consume it and subsequent iterations will result in an empty list:

```
>>> mock.__iter__.return_value = iter(['a', 'b', 'c'])
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
[]
```

MagicMock has all of the supported magic methods configured except for some of the obscure and obsolete ones. You can still set these up if you want.

Magic methods that are supported but not setup by default in MagicMock are:

- `__subclasses__`
- `__dir__`
- `__format__`
- `__get__`, `__set__` and `__delete__`
- `__reversed__` and `__missing__`
- `__reduce__`, `__reduce_ex__`, `__getinitargs__`, `__getnewargs__`, `__getstate__` and `__setstate__`
- `__getformat__`

## 2

Magic methods *should* be looked up on the class rather than the instance. Different versions of Python are inconsistent about applying this rule. The supported protocol methods should work with all supported versions of Python.

The function is basically hooked up to the class, but each `Mock` instance is kept isolated from the others.

## Helpers

### sentinel

`unittest.mock.sentinel`

The `sentinel` object provides a convenient way of providing unique objects for your tests.

Attributes are created on demand when you access them by name. Accessing the same attribute will always return the same object. The objects returned have a sensible `repr` so that test failure messages are readable.

*Changed in version 3.7:* The `sentinel` attributes now preserve their identity when they are **copied** or **pickled**.

Sometimes when testing you need to test that a specific object is passed as an argument to another method, or returned. It can be common to create named sentinel objects to test this. `sentinel` provides a convenient way of creating and testing the identity of objects like this.

In this example we monkey patch `method` to return `sentinel.some_object`:

```
>>> real = ProductionClass()
>>> real.method = Mock(name="method")
>>> real.method.return_value = sentinel.some_object
>>> result = real.method()
>>> assert result is sentinel.some_object
>>> result
sentinel.some_object
```

### DEFAULT

## unittest.mock.DEFAULT

The **DEFAULT** object is a pre-created sentinel (actually `sentinel.DEFAULT`). It can be used by **side\_effect** functions to indicate that the normal return value should be used.

## call

### unittest.mock.call(\*args, \*\*kwargs)

**call()** is a helper object for making simpler assertions, for comparing with **call\_args**, **call\_args\_list**, **mock\_calls** and **method\_calls**. **call()** can also be used with **assert\_has\_calls()**.

```
>>> m = MagicMock(return_value=None)
>>> m(1, 2, a='foo', b='bar')
>>> m()
>>> m.call_args_list == [call(1, 2, a='foo', b='bar')
True
```

### call.call\_list()

For a call object that represents multiple calls, **call\_list()** returns a list of all the intermediate calls as well as the final call.

**call\_list** is particularly useful for making assertions on “chained calls”. A chained call is multiple calls on a single line of code. This results in multiple entries in **mock\_calls** on a mock. Manually constructing the sequence of calls can be tedious.

**call\_list()** can construct the sequence of calls from the same chained call:

```
>>> m = MagicMock()
>>> m(1).method(arg='foo').other('bar')(2.0)
<MagicMock name='mock().method().other()' id='...'>
>>> kall = call(1).method(arg='foo').other('bar')(2.0)
>>> kall.call_list()
```

```
[call(1),
 call().method(arg='foo'),
 call().method().other('bar'),
 call().method().other()(2.0)]
>>> m.mock_calls == kall.call_list()
True
```

A `call` object is either a tuple of (positional args, keyword args) or (name, positional args, keyword args) depending on how it was constructed. When you construct them yourself this isn't particularly interesting, but the `call` objects that are in the `Mock.call_args`, `Mock.call_args_list` and `Mock.mock_calls` attributes can be introspected to get at the individual arguments they contain.

The `call` objects in `Mock.call_args` and `Mock.call_args_list` are two-tuples of (positional args, keyword args) whereas the `call` objects in `Mock.mock_calls`, along with ones you construct yourself, are three-tuples of (name, positional args, keyword args).

You can use their “tupleness” to pull out the individual arguments for more complex introspection and assertions. The positional arguments are a tuple (an empty tuple if there are no positional arguments) and the keyword arguments are a dictionary:

```
>>> m = MagicMock(return_value=None)
>>> m(1, 2, 3, arg='one', arg2='two')
>>> kall = m.call_args
>>> kall.args
(1, 2, 3)
>>> kall.kwargs
{'arg': 'one', 'arg2': 'two'}
>>> kall.args is kall[0]
True
>>> kall.kwargs is kall[1]
True

>>> m = MagicMock()
>>> m.foo(4, 5, 6, arg='two', arg2='three')
```

```

<MagicMock name='mock.foo()' id='... '>
>>> kall = m.mock_calls[0]
>>> name, args, kwargs = kall
>>> name
'foo'
>>> args
(4, 5, 6)
>>> kwargs
{'arg': 'two', 'arg2': 'three'}
>>> name is m.mock_calls[0][0]
True

```

## create\_autospec

`unittest.mock.create_autospec(spec, spec_set=False, instance=False, **kwargs)`

Create a mock object using another object as a spec. Attributes on the mock will use the corresponding attribute on the *spec* object as their spec.

Functions or methods being mocked will have their arguments checked to ensure that they are called with the correct signature.

If *spec\_set* is `True` then attempting to set attributes that don't exist on the spec object will raise an `AttributeError`.

If a class is used as a spec then the return value of the mock (the instance of the class) will have the same spec. You can use a class as the spec for an instance object by passing *instance=True*. The returned mock will only be callable if instances of the mock are callable.

`create_autospec()` also takes arbitrary keyword arguments that are passed to the constructor of the created mock.

See [Autospeccing](#) for examples of how to use auto-speccing with `create_autospec()` and the *autospec* argument to `patch()`.

Changed in version 3.8: `create_autospec()` now returns an `AsyncMock` if the target is an async function.

## ANY

`unittest.mock.ANY`

Sometimes you may need to make assertions about *some* of the arguments in a call to mock, but either not care about some of the arguments or want to pull them individually out of `call_args` and make more complex assertions on them.

To ignore certain arguments you can pass in objects that compare equal to *everything*. Calls to `assert_called_with()` and `assert_called_once_with()` will then succeed no matter what was passed in.

```
>>> mock = Mock(return_value=None)
>>> mock('foo', bar=object())
>>> mock.assert_called_once_with('foo', bar=ANY)
```

**ANY** can also be used in comparisons with call lists like `mock_calls`:

```
>>> m = MagicMock(return_value=None)
>>> m(1)
>>> m(1, 2)
>>> m(object())
>>> m.mock_calls == [call(1), call(1, 2), ANY]
True
```

## FILTER\_DIR

`unittest.mock.FILTER_DIR`

**FILTER\_DIR** is a module level variable that controls the way mock objects respond to `dir()`. The default is `True`, which uses the filtering described below, to only show useful members. If you dislike this filtering, or need to switch it off for diagnostic purposes, then set `mock.FILTER_DIR = False`.

With filtering on, `dir(some_mock)` shows only useful attributes and will include any dynamically created attributes that wouldn't normally be shown. If the mock was created with a *spec* (or *autospec* of course) then all the attributes from the original are shown, even if they haven't been accessed yet:

```
>>> dir(Mock())
['assert_any_call',
 'assert_called',
 'assert_called_once',
 'assert_called_once_with',
 'assert_called_with',
 'assert_has_calls',
 'assert_not_called',
 'attach_mock',
 ...
>>> from urllib import request
>>> dir(Mock(spec=request))
['AbstractBasicAuthHandler',
 'AbstractDigestAuthHandler',
 'AbstractHTTPHandler',
 'BaseHandler',
 ...]
```

Many of the not-very-useful (private to **Mock** rather than the thing being mocked) underscore and double underscore prefixed attributes have been filtered from the result of calling `dir()` on a **Mock**. If you dislike this behaviour you can switch it off by setting the module level switch **`FILTER_DIR`**:

```
>>> from unittest import mock
>>> mock.FILTER_DIR = False
>>> dir(mock.Mock())
['_NonCallableMock__get_return_value',
 '_NonCallableMock__get_side_effect',
 '_NonCallableMock__return_value_doc',
 '_NonCallableMock__set_return_value',
 '_NonCallableMock__set_side_effect',
 '__call__',
```

```
'__class__',  
...
```

Alternatively you can just use `vars(my_mock)` (instance members) and `dir(type(my_mock))` (type members) to bypass the filtering irrespective of `mock.FILTER_DIR`.

## mock\_open

`unittest.mock.mock_open(mock=None, read_data=None)`

A helper function to create a mock to replace the use of `open()`. It works for `open()` called directly or used as a context manager.

The *mock* argument is the mock object to configure. If `None` (the default) then a `MagicMock` will be created for you, with the API limited to methods or attributes available on standard file handles.

*read\_data* is a string for the `read()`, `readline()`, and `readlines()` methods of the file handle to return. Calls to those methods will take data from *read\_data* until it is depleted. The mock of these methods is pretty simplistic: every time the *mock* is called, the *read\_data* is rewound to the start. If you need more control over the data that you are feeding to the tested code you will need to customize this mock for yourself. When that is insufficient, one of the in-memory filesystem packages on [PyPI](https://pypi.org) [https://pypi.org] can offer a realistic filesystem for testing.

*Changed in version 3.4:* Added `readline()` and `readlines()` support. The mock of `read()` changed to consume *read\_data* rather than returning it on each call.

*Changed in version 3.5:* *read\_data* is now reset on each call to the *mock*.

*Changed in version 3.8:* Added `__iter__()` to implementation so that iteration (such as in for loops) correctly consumes *read\_data*.

Using `open()` as a context manager is a great way to ensure your file handles are closed properly and is becoming common:

```
with open('/some/path', 'w') as f:
    f.write('something')
```

The issue is that even if you mock out the call to `open()` it is the *returned object* that is used as a context manager (and has `__enter__()` and `__exit__()` called).

Mocking context managers with a `MagicMock` is common enough and fiddly enough that a helper function is useful.

```
>>> m = mock_open()
>>> with patch('__main__.open', m):
...     with open('foo', 'w') as h:
...         h.write('some stuff')
...
>>> m.mock_calls
[call('foo', 'w'),
 call().__enter__(),
 call().write('some stuff'),
 call().__exit__(None, None, None)]
>>> m.assert_called_once_with('foo', 'w')
>>> handle = m()
>>> handle.write.assert_called_once_with('some stuff')
```

And for reading files:

```
>>> with patch('__main__.open', mock_open(read_data='bibble')):
...     with open('foo') as h:
...         result = h.read()
...
>>> m.assert_called_once_with('foo')
>>> assert result == 'bibble'
```

## Autospeccing

Autospeccing is based on the existing `spec` feature of mock. It limits the api of mocks to the api of an original object (the spec),

but it is recursive (implemented lazily) so that attributes of mocks only have the same api as the attributes of the spec. In addition mocked functions / methods have the same call signature as the original so they raise a `TypeError` if they are called incorrectly.

Before I explain how auto-specing works, here's why it is needed.

`Mock` is a very powerful and flexible object, but it suffers from two flaws when used to mock out objects from a system under test. One of these flaws is specific to the `Mock` api and the other is a more general problem with using mock objects.

First the problem specific to `Mock`. `Mock` has two assert methods that are extremely handy: `assert_called_with()` and `assert_called_once_with()`.

```
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
Traceback (most recent call last):
```

```
...
```

```
AssertionError: Expected 'mock' to be called once. Called
```

Because mocks auto-create attributes on demand, and allow you to call them with arbitrary arguments, if you misspell one of these assert methods then your assertion is gone:

```
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assret_called_once_with(4, 5, 6)  # Intentional
```

Your tests can pass silently and incorrectly because of the typo.

The second issue is more general to mocking. If you refactor some of your code, rename members and so on, any tests for code that is still using the *old api* but uses mocks instead of the real objects will still pass. This means your tests can all pass even though your code is broken.

Note that this is another reason why you need integration tests as well as unit tests. Testing everything in isolation is all fine and dandy, but if you don't test how your units are “wired together” there is still lots of room for bugs that tests might have caught.

**mock** already provides a feature to help with this, called **specing**. If you use a class or instance as the **spec** for a mock then you can only access attributes on the mock that exist on the real class:

```
>>> from urllib import request
>>> mock = Mock(spec=request.Request)
>>> mock.assert_called_with # Intentional typo!
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'assert_called_with'
```

The spec only applies to the mock itself, so we still have the same issue with any methods on the mock:

```
>>> mock.has_data()
<mock.Mock object at 0x...>
>>> mock.has_data.assert_called_with() # Intentional typo!
```

Auto-specing solves this problem. You can either pass `autospec=True` to `patch()` / `patch.object()` or use the `create_autospec()` function to create a mock with a spec. If you use the `autospec=True` argument to `patch()` then the object that is being replaced will be used as the spec object. Because the specing is done “lazily” (the spec is created as attributes on the mock are accessed) you can use it with very complex or deeply nested objects (like modules that import modules that import modules) without a big performance hit.

Here's an example of it in use:

```
>>> from urllib import request
>>> patcher = patch('__main__.request', autospec=True)
>>> mock_request = patcher.start()
>>> request is mock_request
True
```

```
>>> mock_request.Request
<MagicMock name='request.Request' spec='Request' id='...>
```

You can see that **request.Request** has a spec.

**request.Request** takes two arguments in the constructor (one of which is *self*). Here's what happens if we try to call it incorrectly:

```
>>> req = request.Request()
Traceback (most recent call last):
...
TypeError: <lambda>() takes at least 2 arguments (1 given)
```

The spec also applies to instantiated classes (i.e. the return value of specced mocks):

```
>>> req = request.Request('foo')
>>> req
<NonCallableMagicMock name='request.Request()' spec='Request' id='...>
```

**Request** objects are not callable, so the return value of instantiating our mocked out **request.Request** is a non-callable mock. With the spec in place any typos in our asserts will raise the correct error:

```
>>> req.add_header('spam', 'eggs')
<MagicMock name='request.Request().add_header()' id='...>
>>> req.add_header.assert_called_with # Intentional typo
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'assert_called_with'
>>> req.add_header.assert_called_with('spam', 'eggs')
```

In many cases you will just be able to add `autospec=True` to your existing `patch()` calls and then be protected against bugs due to typos and api changes.

As well as using *autospec* through `patch()` there is a `create_autospec()` for creating autospecced mocks directly:

```
>>> from urllib import request
>>> mock_request = create_autospec(request)
```

```
>>> mock_request.Request('foo', 'bar')
<NonCallableMagicMock name='mock.Request()' spec='Request'>
```

This isn't without caveats and limitations however, which is why it is not the default behaviour. In order to know what attributes are available on the spec object, *autospec* has to introspect (access attributes) the spec. As you traverse attributes on the mock a corresponding traversal of the original object is happening under the hood. If any of your specced objects have properties or descriptors that can trigger code execution then you may not be able to use *autospec*. On the other hand it is much better to design your objects so that introspection is safe [4](#).

A more serious problem is that it is common for instance attributes to be created in the `__init__()` method and not to exist on the class at all. *autospec* can't know about any dynamically created attributes and restricts the api to visible attributes.

```
>>> class Something:
...     def __init__(self):
...         self.a = 33
...
>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'
```

There are a few different ways of resolving this problem. The easiest, but not necessarily the least annoying, way is to simply set the required attributes on the mock after creation. Just because *autospec* doesn't allow you to fetch attributes that don't exist on the spec it doesn't prevent you setting them:

```
>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a = 33
... 
```

There is a more aggressive version of both *spec* and *autospec* that *does* prevent you setting non-existent attributes. This is useful if you want to ensure your code only *sets* valid attributes too, but obviously it prevents this particular scenario:

```
>>> with patch('__main__.Something', autospec=True, spec=Something):
...     thing = Something()
...     thing.a = 33
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'
```

Probably the best way of solving the problem is to add class attributes as default values for instance members initialised in `__init__()`. Note that if you are only setting default attributes in `__init__()` then providing them via class attributes (shared between instances of course) is faster too. e.g.

```
class Something:
    a = 33
```

This brings up another issue. It is relatively common to provide a default value of `None` for members that will later be an object of a different type. `None` would be useless as a spec because it wouldn't let you access *any* attributes or methods on it. As `None` is *never* going to be useful as a spec, and probably indicates a member that will normally of some other type, *autospec* doesn't use a spec for members that are set to `None`. These will just be ordinary mocks (well - *MagicMocks*):

```
>>> class Something:
...     member = None
...
>>> mock = create_autospec(Something)
>>> mock.member.foo.bar.baz()
<MagicMock name='mock.member.foo.bar.baz()' id='...'>
```

If modifying your production classes to add defaults isn't to your liking then there are more options. One of these is simply to use an

instance as the spec rather than the class. The other is to create a subclass of the production class and add the defaults to the subclass without affecting the production class. Both of these require you to use an alternative object as the spec. Thankfully `patch()` supports this - you can simply pass the alternative object as the *autospec* argument:

```
>>> class Something:
...     def __init__(self):
...         self.a = 33
...
>>> class SomethingForTest(Something):
...     a = 33
...
>>> p = patch('__main__.Something', autospec=SomethingForTest)
>>> mock = p.start()
>>> mock.a
<NonCallableMagicMock name='Something.a' spec='int' id='...>
```

#### 4

This only applies to classes or already instantiated objects. Calling a mocked class to create a mock instance *does not* create a real instance. It is only attribute lookups - along with calls to `dir()` - that are done.

## Sealing mocks

`unittest.mock.seal(mock)`

Seal will disable the automatic creation of mocks when accessing an attribute of the mock being sealed or any of its attributes that are already mocks recursively.

If a mock instance with a name or a spec is assigned to an attribute it won't be considered in the sealing chain. This allows one to prevent seal from fixing part of the mock object.

```
>>> mock = Mock()
>>> mock.submock.attribute1 = 2
```

```
>>> mock.not_submock = mock.Mock(name="sample_name")
>>> seal(mock)
>>> mock.new_attribute # This will raise AttributeError
>>> mock.submock.attribute2 # This will raise AttributeError
>>> mock.not_submock.attribute2 # This won't raise an error
```

*New in version 3.7.*

*New in version 3.3.*

## Using Mock

### Mock Patching Methods

Common uses for `Mock` objects include:

- Patching methods
- Recording method calls on objects

You might want to replace a method on an object to check that it is called with the correct arguments by another part of the system:

```
>>> real = SomeClass()
>>> real.method = MagicMock(name='method')
>>> real.method(3, 4, 5, key='value')
<MagicMock name='method()' id='...'>
```

Once our mock has been used (`real.method` in this example) it has methods and attributes that allow you to make assertions about how it has been used.

#### Note

In most of these examples the `Mock` and `MagicMock` classes are interchangeable. As the `MagicMock` is the more capable class it makes a sensible one to use by default.

Once the mock has been called its `called` attribute is set to `True`. More importantly we can use the `assert_called_with()` or

`assert_called_once_with()` method to check that it was called with the correct arguments.

This example tests that calling `ProductionClass().method` results in a call to the `something` method:

```
>>> class ProductionClass:
...     def method(self):
...         self.something(1, 2, 3)
...     def something(self, a, b, c):
...         pass
...
>>> real = ProductionClass()
>>> real.something = MagicMock()
>>> real.method()
>>> real.something.assert_called_once_with(1, 2, 3)
```

## Mock for Method Calls on an Object

In the last example we patched a method directly on an object to check that it was called correctly. Another common use case is to pass an object into a method (or some part of the system under test) and then check that it is used in the correct way.

The simple `ProductionClass` below has a `closer` method. If it is called with an object then it calls `close` on it.

```
>>> class ProductionClass:
...     def closer(self, something):
...         something.close()
...
>>>
```

So to test it we need to pass in an object with a `close` method and check that it was called correctly.

```
>>> real = ProductionClass()
>>> mock = Mock()
>>> real.closer(mock)
>>> mock.close.assert_called_with()
```

We don't have to do any work to provide the 'close' method on our mock. Accessing close creates it. So, if 'close' hasn't already been called then accessing it in the test will create it, but `assert_called_with()` will raise a failure exception.

## Mocking Classes

A common use case is to mock out classes instantiated by your code under test. When you patch a class, then that class is replaced with a mock. Instances are created by *calling the class*. This means you access the "mock instance" by looking at the return value of the mocked class.

In the example below we have a function `some_function` that instantiates `Foo` and calls a method on it. The call to `patch()` replaces the class `Foo` with a mock. The `Foo` instance is the result of calling the mock, so it is configured by modifying the mock `return_value`.

```
>>> def some_function():
...     instance = module.Foo()
...     return instance.method()
...
>>> with patch('module.Foo') as mock:
...     instance = mock.return_value
...     instance.method.return_value = 'the result'
...     result = some_function()
...     assert result == 'the result'
```

## Naming your mocks

It can be useful to give your mocks a name. The name is shown in the repr of the mock and can be helpful when the mock appears in test failure messages. The name is also propagated to attributes or methods of the mock:

```
>>> mock = MagicMock(name='foo')
>>> mock
<MagicMock name='foo' id='...'>
>>> mock.method
```

```
<MagicMock name='foo.method' id='... '>
```

## Tracking all Calls

Often you want to track more than a single call to a method. The `mock_calls` attribute records all calls to child attributes of the mock - and also to their children.

```
>>> mock = MagicMock()
>>> mock.method()
<MagicMock name='mock.method()' id='... '>
>>> mock.attribute.method(10, x=53)
<MagicMock name='mock.attribute.method()' id='... '>
>>> mock.mock_calls
[call.method(), call.attribute.method(10, x=53)]
```

If you make an assertion about `mock_calls` and any unexpected methods have been called, then the assertion will fail. This is useful because as well as asserting that the calls you expected have been made, you are also checking that they were made in the right order and with no additional calls:

You use the `call` object to construct lists for comparing with `mock_calls`:

```
>>> expected = [call.method(), call.attribute.method(10,
>>> mock.mock_calls == expected
True
```

However, parameters to calls that return mocks are not recorded, which means it is not possible to track nested calls where the parameters used to create ancestors are important:

```
>>> m = Mock()
>>> m.factory(important=True).deliver()
<Mock name='mock.factory().deliver()' id='... '>
>>> m.mock_calls[-1] == call.factory(important=False).de
True
```

## Setting Return Values and Attributes

Setting the return values on a mock object is trivially easy:

```
>>> mock = Mock()
>>> mock.return_value = 3
>>> mock()
3
```

Of course you can do the same for methods on the mock:

```
>>> mock = Mock()
>>> mock.method.return_value = 3
>>> mock.method()
3
```

The return value can also be set in the constructor:

```
>>> mock = Mock(return_value=3)
>>> mock()
3
```

If you need an attribute setting on your mock, just do it:

```
>>> mock = Mock()
>>> mock.x = 3
>>> mock.x
3
```

Sometimes you want to mock up a more complex situation, like for example `mock.connection.cursor().execute("SELECT 1")`. If we wanted this call to return a list, then we have to configure the result of the nested call.

We can use `call` to construct the set of calls in a “chained call” like this for easy assertion afterwards:

```
>>> mock = Mock()
>>> cursor = mock.connection.cursor.return_value
>>> cursor.execute.return_value = ['foo']
>>> mock.connection.cursor().execute("SELECT 1")
['foo']
>>> expected = call.connection.cursor().execute("SELECT
```

```
>>> mock.mock_calls
[call.connection.cursor(), call.connection.cursor().execu
>>> mock.mock_calls == expected
True
```

It is the call to `.call_list()` that turns our call object into a list of calls representing the chained calls.

## Raising exceptions with mocks

A useful attribute is `side_effect`. If you set this to an exception class or instance then the exception will be raised when the mock is called.

```
>>> mock = Mock(side_effect=Exception('Boom!'))
>>> mock()
Traceback (most recent call last):
...
Exception: Boom!
```

## Side effect functions and iterables

`side_effect` can also be set to a function or an iterable. The use case for `side_effect` as an iterable is where your mock is going to be called several times, and you want each call to return a different value. When you set `side_effect` to an iterable every call to the mock returns the next value from the iterable:

```
>>> mock = MagicMock(side_effect=[4, 5, 6])
>>> mock()
4
>>> mock()
5
>>> mock()
6
```

For more advanced use cases, like dynamically varying the return values depending on what the mock is called with, `side_effect` can be a function. The function will be called with the same arguments as the mock. Whatever the function returns is what the

call returns:

```
>>> vals = {(1, 2): 1, (2, 3): 2}
>>> def side_effect(*args):
...     return vals[args]
...
>>> mock = MagicMock(side_effect=side_effect)
>>> mock(1, 2)
1
>>> mock(2, 3)
2
```

## Mocking asynchronous iterators

Since Python 3.8, `AsyncMock` and `MagicMock` have support to mock [Asynchronous Iterators](#) through `__aiter__`. The `return_value` attribute of `__aiter__` can be used to set the return values to be used for iteration.

```
>>> mock = MagicMock() # AsyncMock also works here
>>> mock.__aiter__.return_value = [1, 2, 3]
>>> async def main():
...     return [i async for i in mock]
...
>>> asyncio.run(main())
[1, 2, 3]
```

## Mocking asynchronous context manager

Since Python 3.8, `AsyncMock` and `MagicMock` have support to mock [Asynchronous Context Managers](#) through `__aenter__` and `__aexit__`. By default, `__aenter__` and `__aexit__` are `AsyncMock` instances that return an async function.

```
>>> class AsyncContextManager:
...     async def __aenter__(self):
...         return self
...     async def __aexit__(self, exc_type, exc, tb):
...         pass
```

```

...
>>> mock_instance = MagicMock(AsyncContextManager()) #
>>> async def main():
...     async with mock_instance as result:
...         pass
...
>>> asyncio.run(main())
>>> mock_instance.__aenter__.assert_awaited_once()
>>> mock_instance.__aexit__.assert_awaited_once()

```

## Creating a Mock from an Existing Object

One problem with over use of mocking is that it couples your tests to the implementation of your mocks rather than your real code. Suppose you have a class that implements `some_method`. In a test for another class, you provide a mock of this object that *also* provides `some_method`. If later you refactor the first class, so that it no longer has `some_method` - then your tests will continue to pass even though your code is now broken!

**Mock** allows you to provide an object as a specification for the mock, using the *spec* keyword argument. Accessing methods / attributes on the mock that don't exist on your specification object will immediately raise an attribute error. If you change the implementation of your specification, then tests that use that class will start failing immediately without you having to instantiate the class in those tests.

```

>>> mock = Mock(spec=SomeClass)
>>> mock.old_method()
Traceback (most recent call last):
...
AttributeError: object has no attribute 'old_method'

```

Using a specification also enables a smarter matching of calls made to the mock, regardless of whether some parameters were passed as positional or named arguments:

```

>>> def f(a, b, c): pass
...

```

```
>>> mock = Mock(spec=f)
>>> mock(1, 2, 3)
<Mock name='mock()' id='140161580456576'>
>>> mock.assert_called_with(a=1, b=2, c=3)
```

If you want this smarter matching to also work with method calls on the mock, you can use [auto-speccing](#).

If you want a stronger form of specification that prevents the setting of arbitrary attributes as well as the getting of them then you can use *spec\_set* instead of *spec*.

## Using *side\_effect* to return per file content

[mock\\_open\(\)](#) is used to patch [open\(\)](#) method. [side\\_effect](#) can be used to return a new Mock object per call. This can be used to return different contents per file stored in a dictionary:

```
DEFAULT = "default"
data_dict = {"file1": "data1",
             "file2": "data2"}

def open_side_effect(name):
    return mock_open(read_data=data_dict.get(name, DEFAULT))

with patch("builtins.open", side_effect=open_side_effect):
    with open("file1") as file1:
        assert file1.read() == "data1"

    with open("file2") as file2:
        assert file2.read() == "data2"

    with open("file3") as file2:
        assert file2.read() == "default"
```

## Patch Decorators

### Note

With `patch()` it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read [where to patch](#).

A common need in tests is to patch a class attribute or a module attribute, for example patching a builtin or patching a class in a module to test that it is instantiated. Modules and classes are effectively global, so patching on them has to be undone after the test or the patch will persist into other tests and cause hard to diagnose problems.

mock provides three convenient decorators for this: `patch()`, `patch.object()` and `patch.dict()`. `patch` takes a single string, of the form `package.module.Class.attribute` to specify the attribute you are patching. It also optionally takes a value that you want the attribute (or class or whatever) to be replaced with. 'patch.object' takes an object and the name of the attribute you would like patched, plus optionally the value to patch it with.

`patch.object`:

```
>>> original = SomeClass.attribute
>>> @patch.object(SomeClass, 'attribute', sentinel.attribute)
... def test():
...     assert SomeClass.attribute == sentinel.attribute
...
>>> test()
>>> assert SomeClass.attribute == original

>>> @patch('package.module.attribute', sentinel.attribute)
... def test():
...     from package.module import attribute
...     assert attribute is sentinel.attribute
...
>>> test()
```

If you are patching a module (including `builtins`) then use `patch()` instead of `patch.object()`:

```
>>> mock = MagicMock(return_value=sentinel.file_handle)
>>> with patch('builtins.open', mock):
...     handle = open('filename', 'r')
...
>>> mock.assert_called_with('filename', 'r')
>>> assert handle == sentinel.file_handle, "incorrect file handle"
```

The module name can be ‘dotted’, in the form `package.module` if needed:

```
>>> @patch('package.module.ClassName.attribute', sentinel.value)
... def test():
...     from package.module import ClassName
...     assert ClassName.attribute == sentinel.value
...
>>> test()
```

A nice pattern is to actually decorate test methods themselves:

```
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'attribute', sentinel.value)
...     def test_something(self):
...         self.assertEqual(SomeClass.attribute, sentinel.value)
...
>>> original = SomeClass.attribute
>>> MyTest('test_something').test_something()
>>> assert SomeClass.attribute == original
```

If you want to patch with a Mock, you can use `patch()` with only one argument (or `patch.object()` with two arguments). The mock will be created for you and passed into the test function / method:

```
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'static_method')
...     def test_something(self, mock_method):
...         SomeClass.static_method()
...         mock_method.assert_called_with()
...
>>> MyTest('test_something').test_something()
```

You can stack up multiple patch decorators using this pattern:

```
>>> class MyTest(unittest.TestCase):
...     @patch('package.module.ClassName1')
...     @patch('package.module.ClassName2')
...     def test_something(self, MockClass2, MockClass1):
...         self.assertIs(package.module.ClassName1, MockClass1)
...         self.assertIs(package.module.ClassName2, MockClass2)
...
>>> MyTest('test_something').test_something()
```

When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal *Python* order that decorators are applied). This means from the bottom up, so in the example above the mock for `test_module.ClassName2` is passed in first.

There is also `patch.dict()` for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True):
...     assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == original
```

`patch`, `patch.object` and `patch.dict` can all be used as context managers.

Where you use `patch()` to create a mock for you, you can get a reference to the mock using the “as” form of the with statement:

```
>>> class ProductionClass:
...     def method(self):
...         pass
...
>>> with patch.object(ProductionClass, 'method') as mock_method:
...     mock_method.return_value = None
```

```
...     real = ProductionClass()
...     real.method(1, 2, 3)
...
>>> mock_method.assert_called_with(1, 2, 3)
```

As an alternative patch, `patch.object` and `patch.dict` can be used as class decorators. When used in this way it is the same as applying the decorator individually to every method whose name starts with “test”.

## Further Examples

Here are some more examples for some slightly more advanced scenarios.

### Mocking chained calls

Mocking chained calls is actually straightforward with `mock` once you understand the `return_value` attribute. When a mock is called for the first time, or you fetch its `return_value` before it has been called, a new `Mock` is created.

This means that you can see how the object returned from a call to a mocked object has been used by interrogating the `return_value` mock:

```
>>> mock = Mock()
>>> mock().foo(a=2, b=3)
<Mock name='mock().foo()' id='...'>
>>> mock.return_value.foo.assert_called_with(a=2, b=3)
```

From here it is a simple step to configure and then make assertions about chained calls. Of course another alternative is writing your code in a more testable way in the first place...

So, suppose we have some code that looks a little bit like this:

```
>>> class Something:
...     def __init__(self):
...         self.backend = BackendProvider()
```

```
...     def method(self):
...         response = self.backend.get_endpoint('foobar')
...         # more code
```

Assuming that `BackendProvider` is already well tested, how do we test `method()`? Specifically, we want to test that the code section `# more code` uses the response object in the correct way.

As this chain of calls is made from an instance attribute we can monkey patch the `backend` attribute on a `Something` instance. In this particular case we are only interested in the return value from the final call to `start_call` so we don't have much configuration to do. Let's assume the object it returns is 'file-like', so we'll ensure that our response object uses the builtin `open()` as its spec.

To do this we create a mock instance as our mock backend and create a mock response object for it. To set the response as the return value for that final `start_call` we could do this:

```
mock_backend.get_endpoint.return_value.create_call.return_value = open('foo')
```

We can do that in a slightly nicer way using the `configure_mock()` method to directly set the return value for us:

```
>>> something = Something()
>>> mock_response = Mock(spec=open)
>>> mock_backend = Mock()
>>> config = {'get_endpoint.return_value.create_call.return_value': mock_response}
>>> mock_backend.configure_mock(**config)
```

With these we monkey patch the “mock backend” in place and can make the real call:

```
>>> something.backend = mock_backend
>>> something.method()
```

Using `mock_calls` we can check the chained call with a single assert. A chained call is several calls in one line of code, so there will be several entries in `mock_calls`. We can use `call.call_list()` to create this list of calls for us:

```
>>> chained = call.get_endpoint('foobar').create_call('s
>>> call_list = chained.call_list()
>>> assert mock_backend.mock_calls == call_list
```

## Partial mocking

In some tests I wanted to mock out a call to `datetime.date.today()` to return a known date, but I didn't want to prevent the code under test from creating new date objects. Unfortunately `datetime.date` is written in C, and so I couldn't just monkey-patch out the static `datetime.date.today()` method.

I found a simple way of doing this that involved effectively wrapping the date class with a mock, but passing through calls to the constructor to the real class (and returning real instances).

The `patch decorator` is used here to mock out the `date` class in the module under test. The `side_effect` attribute on the mock date class is then set to a lambda function that returns a real date. When the mock date class is called a real date will be constructed and returned by `side_effect`.

```
>>> from datetime import date
>>> with patch('mymodule.date') as mock_date:
...     mock_date.today.return_value = date(2010, 10, 8)
...     mock_date.side_effect = lambda *args, **kw: date
...
...     assert mymodule.date.today() == date(2010, 10, 8)
...     assert mymodule.date(2009, 6, 8) == date(2009, 6
```

Note that we don't patch `datetime.date` globally, we patch `date` in the module that *uses* it. See [where to patch](#).

When `date.today()` is called a known date is returned, but calls to the `date(...)` constructor still return normal dates. Without this you can find yourself having to calculate an expected result using exactly the same algorithm as the code under test, which is a classic testing anti-pattern.

Calls to the date constructor are recorded in the `mock_date` attributes (`call_count` and `friends`) which may also be useful for your tests.

An alternative way of dealing with mocking dates, or other builtin classes, is discussed in [this blog entry](https://williambert.online/2011/07/how-to-unit-testing-in-django-with-mocking-and-patching/) [https://williambert.online/2011/07/how-to-unit-testing-in-django-with-mocking-and-patching/].

## Mocking a Generator Method

A Python generator is a function or method that uses the `yield` statement to return a series of values when iterated over [1](#).

A generator method / function is called to return the generator object. It is the generator object that is then iterated over. The protocol method for iteration is `__iter__()`, so we can mock this using a [MagicMock](#).

Here's an example class with an “iter” method implemented as a generator:

```
>>> class Foo:
...     def iter(self):
...         for i in [1, 2, 3]:
...             yield i
...
>>> foo = Foo()
>>> list(foo.iter())
[1, 2, 3]
```

How would we mock this class, and in particular its “iter” method?

To configure the values returned from the iteration (implicit in the call to `list`), we need to configure the object returned by the call to `foo.iter()`.

```
>>> mock_foo = MagicMock()
>>> mock_foo.iter.return_value = iter([1, 2, 3])
>>> list(mock_foo.iter())
[1, 2, 3]
```

There are also generator expressions and more [advanced uses](http://www.dabeaz.com/coroutines/index.html) [http://www.dabeaz.com/coroutines/index.html] of generators, but we aren't concerned about them here. A very good introduction to generators and how powerful they are is: [Generator Tricks for Systems Programmers](http://www.dabeaz.com/generators/) [http://www.dabeaz.com/generators/].

## Applying the same patch to every test method

If you want several patches in place for multiple test methods the obvious way is to apply the patch decorators to every method. This can feel like unnecessary repetition. Instead, you can use `patch()` (in all its various forms) as a class decorator. This applies the patches to all test methods on the class. A test method is identified by methods whose names start with `test`:

```
>>> @patch('mymodule.SomeClass')
... class MyTest(unittest.TestCase):
...
...     def test_one(self, MockSomeClass):
...         self.assertIs(mymodule.SomeClass, MockSomeClass)
...
...     def test_two(self, MockSomeClass):
...         self.assertIs(mymodule.SomeClass, MockSomeClass)
...
...     def not_a_test(self):
...         return 'something'
...
>>> MyTest('test_one').test_one()
>>> MyTest('test_two').test_two()
>>> MyTest('test_two').not_a_test()
'something'
```

An alternative way of managing patches is to use the [patch methods: start and stop](#). These allow you to move the patching into your `setUp` and `tearDown` methods.

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
```

```

...         self.patcher = patch('mymodule.foo')
...         self.mock_foo = self.patcher.start()
...
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
...
...     def tearDown(self):
...         self.patcher.stop()
...
>>> MyTest('test_foo').run()

```

If you use this technique you must ensure that the patching is “undone” by calling `stop`. This can be fiddlier than you might think, because if an exception is raised in the `setUp` then `tearDown` is not called. `unittest.TestCase.addCleanup()` makes this easier:

```

>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         patcher = patch('mymodule.foo')
...         self.addCleanup(patcher.stop)
...         self.mock_foo = patcher.start()
...
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
...
>>> MyTest('test_foo').run()

```

## Mocking Unbound Methods

Whilst writing tests today I needed to patch an *unbound method* (patching the method on the class rather than on the instance). I needed `self` to be passed in as the first argument because I want to make asserts about which objects were calling this particular method. The issue is that you can’t patch with a mock for this, because if you replace an unbound method with a mock it doesn’t become a bound method when fetched from the instance, and so it doesn’t get `self` passed in. The workaround is to patch the unbound method with a real function instead. The `patch()` decorator

makes it so simple to patch out methods with a mock that having to create a real function becomes a nuisance.

If you pass `autospec=True` to patch then it does the patching with a *real* function object. This function object has the same signature as the one it is replacing, but delegates to a mock under the hood. You still get your mock auto-created in exactly the same way as before. What it means though, is that if you use it to patch out an unbound method on a class the mocked function will be turned into a bound method if it is fetched from an instance. It will have `self` passed in as the first argument, which is exactly what I wanted:

```
>>> class Foo:
...     def foo(self):
...         pass
...
>>> with patch.object(Foo, 'foo', autospec=True) as mock_foo:
...     mock_foo.return_value = 'foo'
...     foo = Foo()
...     foo.foo()
...
'foo'
>>> mock_foo.assert_called_once_with(foo)
```

If we don't use `autospec=True` then the unbound method is patched out with a `Mock` instance instead, and isn't called with `self`.

## Checking multiple calls with mock

`mock` has a nice API for making assertions about how your mock objects are used.

```
>>> mock = Mock()
>>> mock.foo_bar.return_value = None
>>> mock.foo_bar('baz', spam='eggs')
>>> mock.foo_bar.assert_called_with('baz', spam='eggs')
```

If your mock is only being called once you can use the

`assert_called_once_with()` method that also asserts that the `call_count` is one.

```
>>> mock.foo_bar.assert_called_once_with('baz', spam='eggs')
>>> mock.foo_bar()
>>> mock.foo_bar.assert_called_once_with('baz', spam='eggs')
Traceback (most recent call last):
...
AssertionError: Expected to be called once. Called 2 times
```

Both `assert_called_with` and `assert_called_once_with` make assertions about the *most recent* call. If your mock is going to be called several times, and you want to make assertions about *all* those calls you can use `call_args_list`:

```
>>> mock = Mock(return_value=None)
>>> mock(1, 2, 3)
>>> mock(4, 5, 6)
>>> mock()
>>> mock.call_args_list
[call(1, 2, 3), call(4, 5, 6), call()]
```

The `call` helper makes it easy to make assertions about these calls. You can build up a list of expected calls and compare it to `call_args_list`. This looks remarkably similar to the repr of the `call_args_list`:

```
>>> expected = [call(1, 2, 3), call(4, 5, 6), call()]
>>> mock.call_args_list == expected
True
```

## Coping with mutable arguments

Another situation is rare, but can bite you, is when your mock is called with mutable arguments. `call_args` and `call_args_list` store *references* to the arguments. If the arguments are mutated by the code under test then you can no longer make assertions about what the values were when the mock was called.

Here's some example code that shows the problem. Imagine the following functions defined in 'mymodule':

```
def frob(val):  
    pass  
  
def grob(val):  
    "First frob and then clear val"  
    frob(val)  
    val.clear()
```

When we try to test that `grob` calls `frob` with the correct argument look what happens:

```
>>> with patch('mymodule.frob') as mock_frob:  
...     val = {6}  
...     mymodule.grob(val)  
...  
>>> val  
set()  
>>> mock_frob.assert_called_with({6})  
Traceback (most recent call last):  
...  
AssertionError: Expected: (({6},),, {})  
Called with: ((set(),),, {})
```

One possibility would be for mock to copy the arguments you pass in. This could then cause problems if you do assertions that rely on object identity for equality.

Here's one solution that uses the [side\\_effect](#) functionality. If you provide a `side_effect` function for a mock then `side_effect` will be called with the same args as the mock. This gives us an opportunity to copy the arguments and store them for later assertions. In this example I'm using *another* mock to store the arguments so that I can use the mock methods for doing the assertion. Again a helper function sets this up for me.

```
>>> from copy import deepcopy  
>>> from unittest.mock import Mock, patch, DEFAULT
```

```

>>> def copy_call_args(mock):
...     new_mock = Mock()
...     def side_effect(*args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         new_mock(*args, **kwargs)
...         return DEFAULT
...     mock.side_effect = side_effect
...     return new_mock
...
>>> with patch('mymodule.frob') as mock_frob:
...     new_mock = copy_call_args(mock_frob)
...     val = {6}
...     mymodule.grob(val)
...
>>> new_mock.assert_called_with({6})
>>> new_mock.call_args
call({6})

```

`copy_call_args` is called with the mock that will be called. It returns a new mock that we do the assertion on. The `side_effect` function makes a copy of the args and calls our `new_mock` with the copy.

## Note

If your mock is only going to be used once there is an easier way of checking arguments at the point they are called. You can simply do the checking inside a `side_effect` function.

```

>>> def side_effect(arg):
...     assert arg == {6}
...
>>> mock = Mock(side_effect=side_effect)
>>> mock({6})
>>> mock(set())
Traceback (most recent call last):
...
AssertionError

```

An alternative approach is to create a subclass of **Mock** or **MagicMock** that copies (using **copy.deepcopy()**) the arguments. Here's an example implementation:

```
>>> from copy import deepcopy
>>> class CopyingMock(MagicMock):
...     def __call__(self, /, *args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         return super().__call__(*args, **kwargs)
...
>>> c = CopyingMock(return_value=None)
>>> arg = set()
>>> c(arg)
>>> arg.add(1)
>>> c.assert_called_with(set())
>>> c.assert_called_with(arg)
Traceback (most recent call last):
...
AssertionError: Expected call: mock({1})
Actual call: mock(set())
>>> c.foo
<CopyingMock name='mock.foo' id='... '>
```

When you subclass **Mock** or **MagicMock** all dynamically created attributes, and the **return\_value** will use your subclass automatically. That means all children of a **CopyingMock** will also have the type **CopyingMock**.

## Nesting Patches

Using **patch** as a context manager is nice, but if you do multiple patches you can end up with nested with statements indenting further and further to the right:

```
>>> class MyTest(unittest.TestCase):
...
...     def test_foo(self):
...         with patch('mymodule.Foo') as mock_foo:
```

```

...         with patch('mymodule.Bar') as mock_bar:
...             with patch('mymodule.Spam') as mock_spam:
...                 assert mymodule.Foo is mock_foo
...                 assert mymodule.Bar is mock_bar
...                 assert mymodule.Spam is mock_spam
...
>>> original = mymodule.Foo
>>> MyTest('test_foo').test_foo()
>>> assert mymodule.Foo is original

```

With `unittest` cleanup functions and the [patch methods: start and stop](#) we can achieve the same effect without the nested indentation. A simple helper method, `create_patch`, puts the patch in place and returns the created mock for us:

```

>>> class MyTest(unittest.TestCase):
...
...     def create_patch(self, name):
...         patcher = patch(name)
...         thing = patcher.start()
...         self.addCleanup(patcher.stop)
...         return thing
...
...     def test_foo(self):
...         mock_foo = self.create_patch('mymodule.Foo')
...         mock_bar = self.create_patch('mymodule.Bar')
...         mock_spam = self.create_patch('mymodule.Spam')
...
...         assert mymodule.Foo is mock_foo
...         assert mymodule.Bar is mock_bar
...         assert mymodule.Spam is mock_spam
...
>>> original = mymodule.Foo
>>> MyTest('test_foo').run()
>>> assert mymodule.Foo is original

```

## Mocking a dictionary with MagicMock

You may want to mock a dictionary, or other container object,

recording all access to it whilst having it still behave like a dictionary.

We can do this with `MagicMock`, which will behave like a dictionary, and using `side_effect` to delegate dictionary access to a real underlying dictionary that is under our control.

When the `__getitem__()` and `__setitem__()` methods of our `MagicMock` are called (normal dictionary access) then `side_effect` is called with the key (and in the case of `__setitem__` the value too). We can also control what is returned.

After the `MagicMock` has been used we can use attributes like `call_args_list` to assert about how the dictionary was used:

```
>>> my_dict = {'a': 1, 'b': 2, 'c': 3}
>>> def getitem(name):
...     return my_dict[name]
...
>>> def setitem(name, val):
...     my_dict[name] = val
...
>>> mock = MagicMock()
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

## Note

An alternative to using `MagicMock` is to use `Mock` and *only* provide the magic methods you specifically want:

```
>>> mock = Mock()
>>> mock.__getitem__ = Mock(side_effect=getitem)
>>> mock.__setitem__ = Mock(side_effect=setitem)
```

A *third* option is to use `MagicMock` but passing in `dict` as the *spec* (or *spec\_set*) argument so that the `MagicMock` created only has dictionary magic methods available:

```
>>> mock = MagicMock(spec_set=dict)
```

```
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

With these side effect functions in place, the `mock` will behave like a normal dictionary but recording the access. It even raises a **KeyError** if you try to access a key that doesn't exist.

```
>>> mock['a']
1
>>> mock['c']
3
>>> mock['d']
Traceback (most recent call last):
...
KeyError: 'd'
>>> mock['b'] = 'fish'
>>> mock['d'] = 'eggs'
>>> mock['b']
'fish'
>>> mock['d']
'eggs'
```

After it has been used you can make assertions about the access using the normal mock methods and attributes:

```
>>> mock.__getitem__.call_args_list
[call('a'), call('c'), call('d'), call('b'), call('d')]
>>> mock.__setitem__.call_args_list
[call('b', 'fish'), call('d', 'eggs')]
>>> my_dict
{'a': 1, 'b': 'fish', 'c': 3, 'd': 'eggs'}
```

## Mock subclasses and their attributes

There are various reasons why you might want to subclass **Mock**. One reason might be to add helper methods. Here's a silly example:

```
>>> class MyMock(MagicMock):
...     def has_been_called(self):
```

```

...         return self.called
...
>>> mymock = MyMock(return_value=None)
>>> mymock
<MyMock id='...'>
>>> mymock.has_been_called()
False
>>> mymock()
>>> mymock.has_been_called()
True

```

The standard behaviour for `Mock` instances is that attributes and the return value mocks are of the same type as the mock they are accessed on. This ensures that `Mock` attributes are `Mocks` and `MagicMock` attributes are `MagicMocks` [2](#). So if you're subclassing to add helper methods then they'll also be available on the attributes and return value mock of instances of your subclass.

```

>>> mymock.foo
<MyMock name='mock.foo' id='...'>
>>> mymock.foo.has_been_called()
False
>>> mymock.foo()
<MyMock name='mock.foo()' id='...'>
>>> mymock.foo.has_been_called()
True

```

Sometimes this is inconvenient. For example, [one user](https://code.google.com/archive/p/mock/issues/105) [https://code.google.com/archive/p/mock/issues/105] is subclassing `mock` to create a [Twisted adaptor](https://twisted.org/documents/11.0.0/api/twisted.python.components.html) [https://twisted.org/documents/11.0.0/api/twisted.python.components.html]. Having this applied to attributes too actually causes errors.

`Mock` (in all its flavours) uses a method called `_get_child_mock` to create these “sub-mocks” for attributes and return values. You can prevent your subclass being used for attributes by overriding this method. The signature is that it takes arbitrary keyword arguments (`**kwargs`) which are then passed onto the mock constructor:

```
>>> class Subclass(MagicMock):
...     def _get_child_mock(self, /, **kwargs):
...         return MagicMock(**kwargs)
...
>>> mymock = Subclass()
>>> mymock.foo
<MagicMock name='mock.foo' id='...'>
>>> assert isinstance(mymock, Subclass)
>>> assert not isinstance(mymock.foo, Subclass)
>>> assert not isinstance(mymock(), Subclass)
```

## 2

An exception to this rule are the non-callable mocks. Attributes use the callable variant because otherwise non-callable mocks couldn't have callable methods.

## Mocking imports with patch.dict

One situation where mocking can be hard is where you have a local import inside a function. These are harder to mock because they aren't using an object from the module namespace that we can patch out.

Generally local imports are to be avoided. They are sometimes done to prevent circular dependencies, for which there is *usually* a much better way to solve the problem (refactor the code) or to prevent “up front costs” by delaying the import. This can also be solved in better ways than an unconditional local import (store the module as a class or module attribute and only do the import on first use).

That aside there is a way to use `mock` to affect the results of an import. Importing fetches an *object* from the `sys.modules` dictionary. Note that it fetches an *object*, which need not be a module. Importing a module for the first time results in a module object being put in `sys.modules`, so usually when you import something you get a module back. This need not be the case however.

This means you can use `patch.dict()` to temporarily put a mock in place in `sys.modules`. Any imports whilst this patch is active

will fetch the mock. When the patch is complete (the decorated function exits, the with statement body is complete or `patcher.stop()` is called) then whatever was there previously will be restored safely.

Here's an example that mocks out the 'fooble' module.

```
>>> import sys
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock}):
...     import fooble
...     fooble.blob()
...
<Mock name='mock.blob()' id='... '>
>>> assert 'fooble' not in sys.modules
>>> mock.blob.assert_called_once_with()
```

As you can see the `import fooble` succeeds, but on exit there is no 'fooble' left in `sys.modules`.

This also works for the `from module import name` form:

```
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock}):
...     from fooble import blob
...     blob.blip()
...
<Mock name='mock.blob.blip()' id='... '>
>>> mock.blob.blip.assert_called_once_with()
```

With slightly more work you can also mock package imports:

```
>>> mock = Mock()
>>> modules = {'package': mock, 'package.module': mock.m
>>> with patch.dict('sys.modules', modules):
...     from package.module import fooble
...     fooble()
...
<Mock name='mock.module.fooble()' id='... '>
>>> mock.module.fooble.assert_called_once_with()
```

## Tracking order of calls and less verbose call assertions

The `Mock` class allows you to track the *order* of method calls on your mock objects through the `method_calls` attribute. This doesn't allow you to track the order of calls between separate mock objects, however we can use `mock_calls` to achieve the same effect.

Because mocks track calls to child mocks in `mock_calls`, and accessing an arbitrary attribute of a mock creates a child mock, we can create our separate mocks from a parent one. Calls to those child mock will then all be recorded, in order, in the `mock_calls` of the parent:

```
>>> manager = Mock()
>>> mock_foo = manager.foo
>>> mock_bar = manager.bar

>>> mock_foo.something()
<Mock name='mock.foo.something()' id='... '>
>>> mock_bar.other.thing()
<Mock name='mock.bar.other.thing()' id='... '>

>>> manager.mock_calls
[call.foo.something(), call.bar.other.thing()]
```

We can then assert about the calls, including the order, by comparing with the `mock_calls` attribute on the manager mock:

```
>>> expected_calls = [call.foo.something(), call.bar.other.thing()]
>>> manager.mock_calls == expected_calls
True
```

If `patch` is creating, and putting in place, your mocks then you can attach them to a manager mock using the `attach_mock()` method. After attaching calls will be recorded in `mock_calls` of the manager.

```
>>> manager = MagicMock()
>>> with patch('mymodule.Class1') as MockClass1:
...     with patch('mymodule.Class2') as MockClass2:
```

```

...         manager.attach_mock(MockClass1, 'MockClass1')
...         manager.attach_mock(MockClass2, 'MockClass2')
...         MockClass1().foo()
...         MockClass2().bar()
<MagicMock name='mock.MockClass1().foo()' id='... '>
<MagicMock name='mock.MockClass2().bar()' id='... '>
>>> manager.mock_calls
[call.MockClass1(),
call.MockClass1().foo(),
call.MockClass2(),
call.MockClass2().bar()]

```

If many calls have been made, but you're only interested in a particular sequence of them then an alternative is to use the `assert_has_calls()` method. This takes a list of calls (constructed with the `call` object). If that sequence of calls are in `mock_calls` then the assert succeeds.

```

>>> m = MagicMock()
>>> m().foo().bar().baz()
<MagicMock name='mock().foo().bar().baz()' id='... '>
>>> m.one().two().three()
<MagicMock name='mock.one().two().three()' id='... '>
>>> calls = call.one().two().three().call_list()
>>> m.assert_has_calls(calls)

```

Even though the chained call `m.one().two().three()` aren't the only calls that have been made to the mock, the assert still succeeds.

Sometimes a mock may have several calls made to it, and you are only interested in asserting about *some* of those calls. You may not even care about the order. In this case you can pass `any_order=True` to `assert_has_calls`:

```

>>> m = MagicMock()
>>> m(1), m.two(2, 3), m.seven(7), m.fifty('50')
(...)
>>> calls = [call.fifty('50'), call(1), call.seven(7)]
>>> m.assert_has_calls(calls, any_order=True)

```

## More complex argument matching

Using the same basic concept as **ANY** we can implement matchers to do more complex assertions on objects used as arguments to mocks.

Suppose we expect some object to be passed to a mock that by default compares equal based on object identity (which is the Python default for user defined classes). To use `assert_called_with()` we would need to pass in the exact same object. If we are only interested in some of the attributes of this object then we can create a matcher that will check these attributes for us.

You can see in this example how a ‘standard’ call to `assert_called_with` isn’t sufficient:

```
>>> class Foo:
...     def __init__(self, a, b):
...         self.a, self.b = a, b
...
>>> mock = Mock(return_value=None)
>>> mock(Foo(1, 2))
>>> mock.assert_called_with(Foo(1, 2))
Traceback (most recent call last):
...
AssertionError: Expected: call(<__main__.Foo object at 0x...>)
Actual call: call(<__main__.Foo object at 0x...>)
```

A comparison function for our `Foo` class might look something like this:

```
>>> def compare(self, other):
...     if not type(self) == type(other):
...         return False
...     if self.a != other.a:
...         return False
...     if self.b != other.b:
...         return False
...     return True
```

```
...
```

And a matcher object that can use comparison functions like this for its equality operation would look something like this:

```
>>> class Matcher:
...     def __init__(self, compare, some_obj):
...         self.compare = compare
...         self.some_obj = some_obj
...     def __eq__(self, other):
...         return self.compare(self.some_obj, other)
... 
```

Putting all this together:

```
>>> match_foo = Matcher(compare, Foo(1, 2))
>>> mock.assert_called_with(match_foo)
```

The `Matcher` is instantiated with our `compare` function and the `Foo` object we want to compare against. In `assert_called_with` the `Matcher` equality method will be called, which compares the object the mock was called with against the one we created our matcher with. If they match then `assert_called_with` passes, and if they don't an **`AssertionError`** is raised:

```
>>> match_wrong = Matcher(compare, Foo(3, 4))
>>> mock.assert_called_with(match_wrong)
Traceback (most recent call last):
```

```
...
AssertionError: Expected: ((<Matcher object at 0x...>,),)
Called with: ((<Foo object at 0x...>,),, {})
```

With a bit of tweaking you could have the comparison function raise the **`AssertionError`** directly and provide a more useful failure message.

As of version 1.5, the Python testing library **`PyHamcrest`** [<https://pyhamcrest.readthedocs.io/>] provides similar functionality, that may be useful here, in the form of its equality matcher ([hamcrest.library.integration.match\\_equality](https://pyhamcrest.readthedocs.io/en/latest/reference.html#hamcrest.library.integration.match_equality) [[https://](https://pyhamcrest.readthedocs.io/en/latest/reference.html#hamcrest.library.integration.match_equality)

`pyhamcrest.readthedocs.io/en/release-1.8/integration/#module-hamcrest.library.integration.match_equality]]).`

# 2to3 — Automated Python 2 to 3 code translation

2to3 is a Python program that reads Python 2.x source code and applies a series of *fixers* to transform it into valid Python 3.x code. The standard library contains a rich set of fixers that will handle almost all code. 2to3 supporting library `lib2to3` is, however, a flexible and generic library, so it is possible to write your own fixers for 2to3.

*Deprecated since version 3.11, will be removed in version 3.13:* The `lib2to3` module was marked pending for deprecation in Python 3.9 (raising `PendingDeprecationWarning` on import) and fully deprecated in Python 3.11 (raising `DeprecationWarning`). The `2to3` tool is part of that. It will be removed in Python 3.13.

## Using 2to3

2to3 will usually be installed with the Python interpreter as a script. It is also located in the `Tools/scripts` directory of the Python root.

2to3's basic arguments are a list of files or directories to transform. The directories are recursively traversed for Python sources.

Here is a sample Python 2.x source file, `example.py`:

```
def greet(name):
    print "Hello, {0}!".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

It can be converted to Python 3.x code via 2to3 on the command line:

```
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (A backup of the original file is made unless `-n` is also given.) Writing the changes back is enabled with the `-w` flag:

```
$ 2to3 -w example.py
```

After transformation, `example.py` looks like this:

```
def greet(name):  
    print("Hello, {0}!".format(name))  
print("What's your name?")  
name = input()  
greet(name)
```

Comments and exact indentation are preserved throughout the translation process.

By default, 2to3 runs a set of [predefined fixers](#). The `-l` flag lists all available fixers. An explicit set of fixers to run can be given with `-f`. Likewise the `-x` explicitly disables a fixer. The following example runs only the `imports` and `has_key` fixers:

```
$ 2to3 -f imports -f has_key example.py
```

This command runs every fixer except the `apply` fixer:

```
$ 2to3 -x apply example.py
```

Some fixers are *explicit*, meaning they aren't run by default and must be listed on the command line to be run. Here, in addition to the default fixers, the `idioms` fixer is run:

```
$ 2to3 -f all -f idioms example.py
```

Notice how passing `all` enables all default fixers.

Sometimes 2to3 will find a place in your source code that needs to be changed, but 2to3 cannot fix automatically. In this case, 2to3 will print a warning beneath the diff for a file. You should address

the warning in order to have compliant 3.x code.

2to3 can also refactor doctests. To enable this mode, use the **-d** flag. Note that *only* doctests will be refactored. This also doesn't require the module to be valid Python. For example, doctest like examples in a reST document could also be refactored with this option.

The **-v** option enables output of more information on the translation process.

Since some print statements can be parsed as function calls or statements, 2to3 cannot always read files containing the print function. When 2to3 detects the presence of the `from __future__ import print_function` compiler directive, it modifies its internal grammar to interpret `print()` as a function. This change can also be enabled manually with the **-p** flag. Use **-p** to run fixers on code that already has had its print statements converted. Also **-e** can be used to make `exec()` a function.

The **-o** or **--output-dir** option allows specification of an alternate directory for processed output files to be written to. The **-n** flag is required when using this as backup files do not make sense when not overwriting the input files.

*New in version 3.2.3:* The **-o** option was added.

The **-W** or **--write-unchanged-files** flag tells 2to3 to always write output files even if no changes were required to the file. This is most useful with **-o** so that an entire Python source tree is copied with translation from one directory to another. This option implies the **-w** flag as it would not make sense otherwise.

*New in version 3.2.3:* The **-W** flag was added.

The **--add-suffix** option specifies a string to append to all output filenames. The **-n** flag is required when specifying this as backups are not necessary when writing to different filenames. Example:

```
$ 2to3 -n -W --add-suffix=3 example.py
```

Will cause a converted file named `example.py3` to be written.

*New in version 3.2.3:* The **`--add-suffix`** option was added.

To translate an entire project from one directory tree to another use:

```
$ 2to3 --output-dir=python3-version/mycode -W -n python2
```

## Fixers

Each step of transforming code is encapsulated in a fixer. The command `2to3 -l` lists them. As [documented above](#), each can be turned on and off individually. They are described here in more detail.

### apply

Removes usage of **`apply()`**. For example

`apply(function, *args, **kwargs)` is converted to `function(*args, **kwargs)`.

### asserts

Replaces deprecated [unittest](#) method names with the correct ones.

#### From

---

```
assertEqual(a, b)
```

---

```
assertEqual(a, b)
```

---

```
assertNotEqual(a, b)
```

---

```
assertNotEqual(a, b)
```

---

```
assertTrue(a)
```

---

```
assertTrue(a)
```

---

```
assertFalse(a)
```

```
assertAlmostEqual(a, b)
```

---

```
assertNotAlmostEqual(a, b)
```

---

```
assertNotAlmostEqual(a, b)
```

---

basestring

Converts `basestring` to `str`.

buffer

Converts `buffer` to `memoryview`. This fixer is optional because the `memoryview` API is similar but not exactly the same as that of `buffer`.

dict

Fixes dictionary iteration methods. `dict.iteritems()` is converted to `dict.items()`, `dict.iterkeys()` to `dict.keys()`, and `dict.itervalues()` to `dict.values()`. Similarly, `dict.viewitems()`, `dict.viewkeys()` and `dict.viewvalues()` are converted respectively to `dict.items()`, `dict.keys()` and `dict.values()`. It also wraps existing usages of `dict.items()`, `dict.keys()`, and `dict.values()` in a call to `list`.

except

Converts `except X, T` to `except X as T`.

exec

Converts the `exec` statement to the `exec()` function.

execfile

Removes usage of `execfile()`. The argument to `execfile()` is wrapped in calls to `open()`, `compile()`, and `exec()`.

exitfunc

Changes assignment of `sys.exitfunc` to use of the `atexit` module.

filter

Wraps `filter()` usage in a `list` call.

## funcattrs

Fixes function attributes that have been renamed. For example, `my_function.func_closure` is converted to `my_function.__closure__`.

## future

Removes from `__future__` import new\_feature statements.

## getcwdu

Renames `os.getcwdu()` to `os.getcwd()`.

## has\_key

Changes `dict.has_key(key)` to `key in dict`.

## idioms

This optional fixer performs several transformations that make Python code more idiomatic. Type comparisons like `type(x) is SomeClass` and `type(x) == SomeClass` are converted to `isinstance(x, SomeClass)`. `while 1` becomes `while True`. This fixer also tries to make use of `sorted()` in appropriate places. For example, this block

```
L = list(some_iterable)
L.sort()
```

is changed to

```
L = sorted(some_iterable)
```

## import

Detects sibling imports and converts them to relative imports.

## imports

Handles module renames in the standard library.

## imports2

Handles other modules renames in the standard library. It is

separate from the `imports` fixer only because of technical limitations.

## input

Converts `input(prompt)` to `eval(input(prompt))`.

## intern

Converts `intern()` to `sys.intern()`.

## isinstance

Fixes duplicate types in the second argument of `isinstance()`. For example, `isinstance(x, (int, int))` is converted to `isinstance(x, int)` and `isinstance(x, (int, float, int))` is converted to `isinstance(x, (int, float))`.

## itertools\_imports

Removes imports of `itertools.ifilter()`, `itertools.izip()`, and `itertools.imap()`. Imports of `itertools.ifilterfalse()` are also changed to `itertools.filterfalse()`.

## itertools

Changes usage of `itertools.ifilter()`, `itertools.izip()`, and `itertools.imap()` to their built-in equivalents. `itertools.ifilterfalse()` is changed to `itertools.filterfalse()`.

## long

Renames `long` to `int`.

## map

Wraps `map()` in a `list` call. It also changes `map(None, x)` to `list(x)`. Using `from future_builtins import map` disables this fixer.

## metaclass

Converts the old metaclass syntax (`__metaclass__ = Meta` in the class body) to the new (`class X(metaclass=Meta)`).

## methodattrs

Fixes old method attribute names. For example, `meth.im_func` is converted to `meth.__func__`.

## ne

Converts the old not-equal syntax, `<>`, to `!=`.

## next

Converts the use of iterator's `next()` methods to the `next()` function. It also renames `next()` methods to `__next__()`.

## nonzero

Renames definitions of methods called `__nonzero__()` to `__bool__()`.

## numliterals

Converts octal literals into the new syntax.

## operator

Converts calls to various functions in the `operator` module to other, but equivalent, function calls. When needed, the appropriate `import` statements are added, e.g. `import collections.abc`. The following mapping are made:

### From

---

<code>operator.attrgetter(attr)(obj)</code>
---------------------------------------------

---

<code>operator.sequenceInjuncts(obj)</code>
---------------------------------------------

---

<code>operator.SequenceType(obj).abc.Sequence</code>
------------------------------------------------------

---

<code>operator.MappingType(obj).abc.Mapping</code>
----------------------------------------------------

---

<code>operator.NumberType(obj).number</code>
----------------------------------------------

---

<code>operator.method(obj, n)</code>
--------------------------------------

---

<code>operator.inplace(obj, n)</code>
---------------------------------------

---

paren

Add extra parenthesis where they are required in list comprehensions. For example, `[x for x in 1, 2]` becomes `[x for x in (1, 2)]`.

print

Converts the `print` statement to the `print()` function.

raise

Converts `raise E, V` to `raise E(V)`, and `raise E, V, T` to `raise E(V).with_traceback(T)`. If `E` is a tuple, the translation will be incorrect because substituting tuples for exceptions has been removed in 3.0.

raw\_input

Converts `raw_input()` to `input()`.

reduce

Handles the move of `reduce()` to `functools.reduce()`.

reload

Converts `reload()` to `importlib.reload()`.

renames

Changes `sys.maxint` to `sys.maxsize`.

repr

Replaces backtick repr with the `repr()` function.

set\_literal

Replaces use of the `set` constructor with set literals. This fixer is optional.

standarderror

Renames `StandardError` to `Exception`.

## sys\_exc

Changes the deprecated `sys.exc_value`, `sys.exc_type`, `sys.exc_traceback` to use `sys.exc_info()`.

## throw

Fixes the API change in generator's `throw()` method.

## tuple\_params

Removes implicit tuple parameter unpacking. This fixer inserts temporary variables.

## types

Fixes code broken from the removal of some members in the `types` module.

## unicode

Renames `unicode` to `str`.

## urllib

Handles the rename of `urllib` and `urllib2` to the `urllib` package.

## ws\_comma

Removes excess whitespace from comma separated items. This fixer is optional.

## xrange

Renames `xrange()` to `range()` and wraps existing `range()` calls with `list`.

## xreadlines

Changes `for x in file.xreadlines()` to `for x in file`.

## zip

Wraps `zip()` usage in a `list` call. This is disabled when

```
from future_builtins import zip appears.
```

## lib2to3 — 2to3's library

**Source code:** [Lib/lib2to3/](https://github.com/python/cpython/tree/3.12/Lib/lib2to3/) [https://github.com/python/cpython/tree/3.12/Lib/lib2to3/]

---

*Deprecated since version 3.11, will be removed in version 3.13:* Python 3.9 switched to a PEG parser (see [PEP 617](https://peps.python.org/pep-0617/) [https://peps.python.org/pep-0617/]) while lib2to3 is using a less flexible LL(1) parser. Python 3.10 includes new language syntax that is not parsable by lib2to3's LL(1) parser (see [PEP 634](https://peps.python.org/pep-0634/) [https://peps.python.org/pep-0634/]). The lib2to3 module was marked pending for deprecation in Python 3.9 (raising [PendingDeprecationWarning](#) on import) and fully deprecated in Python 3.11 (raising [DeprecationWarning](#)). It will be removed from the standard library in Python 3.13. Consider third-party alternatives such as [LibCST](https://libcst.readthedocs.io/) [https://libcst.readthedocs.io/] or [parso](https://parso.readthedocs.io/) [https://parso.readthedocs.io/].

### Note

The [lib2to3](#) API should be considered unstable and may change drastically in the future.

# test — Regression tests package for Python

## Note

The `test` package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python’s standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

---

The `test` package contains all regression tests for Python as well as the modules `test.support` and `test.regrtest`. `test.support` is used to enhance your tests while `test.regrtest` drives the testing suite.

Each module in the `test` package whose name starts with `test_` is a testing suite for a specific module or feature. All new tests should be written using the `unittest` or `doctest` module. Some older tests are written using a “traditional” testing style that compares output printed to `sys.stdout`; this style of test is considered deprecated.

## See also

### Module `unittest`

Writing PyUnit regression tests.

### Module `doctest`

Tests embedded in documentation strings.

## Writing Unit Tests for the `test` package

It is preferred that tests that use the `unittest` module follow a few guidelines. One is to name the test module by starting it with `test_` and end it with the name of the module being tested. The test methods in the test module should start with `test_` and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as `# Tests function returns only True or False`) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```
import unittest
from test import support

class MyTestCase1(unittest.TestCase):

    # Only use setUp() and tearDown() if necessary

    def setUp(self):
        ... code to execute in preparation for tests ...

    def tearDown(self):
        ... code to execute to clean up after tests ...

    def test_feature_one(self):
        # Test feature one.
        ... testing code ...

    def test_feature_two(self):
        # Test feature two.
        ... testing code ...

    ... more test methods ...

class MyTestCase2(unittest.TestCase):
    ... same structure as MyTestCase1 ...
```

```
... more test classes ...  
  
if __name__ == '__main__':  
    unittest.main()
```

This code pattern allows the testing suite to be run by **test.regrtest**, on its own as a script that supports the **unittest** CLI, or via the `python -m unittest` CLI.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also “private” code.
- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.
- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.
- Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.
- Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.
- Make sure to clean up after your tests (such as close and remove all temporary files).
- If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.

- Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.
- Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

```
class TestFuncAcceptsSequencesMixin:
```

```
    func = mySuperWhammyFunction
```

```
    def test_func(self):
        self.func(self.arg)
```

```
class AcceptLists(TestFuncAcceptsSequencesMixin, unittest.TestCase):
    arg = [1, 2, 3]
```

```
class AcceptStrings(TestFuncAcceptsSequencesMixin, unittest.TestCase):
    arg = 'abc'
```

```
class AcceptTuples(TestFuncAcceptsSequencesMixin, unittest.TestCase):
    arg = (1, 2, 3)
```

When using this pattern, remember that all classes that inherit from `unittest.TestCase` are run as tests. The **Mixin** class in the example above does not have any data and so can't be run by itself, thus it does not inherit from `unittest.TestCase`.

See also

### Test Driven Development

A book by Kent Beck on writing tests before code.

## Running tests using the command-line

## interface

The `test` package can be run as a script to drive Python's regression test suite, thanks to the `-m` option: **`python -m test`**. Under the hood, it uses `test.regrtest`; the call **`python -m test.regrtest`** used in previous Python versions still works. Running the script by itself automatically starts running all regression tests in the `test` package. It does this by finding all modules in the package whose name starts with `test_`, importing them, and executing the function `test_main()` if present or loading the tests via `unittest.TestLoader.loadTestsFromModule` if `test_main` does not exist. The names of tests to execute may also be passed to the script. Specifying a single regression test (**`python -m test test_spam`**) will minimize output and only print whether the test passed or failed.

Running `test` directly allows what resources are available for tests to use to be set. You do this by using the `-u` command-line option. Specifying `all` as the value for the `-u` option enables all possible resources: **`python -m test -uall`**. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after `all`. The command **`python -m test -uall,-audio,-largefile`** will run `test` with all resources except the `audio` and `largefile` resources. For a list of all resources and more command-line options, run **`python -m test -h`**.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run **`make test`** at the top-level directory where Python was built. On Windows, executing `rt.bat` from your `PCbuild` directory will run all regression tests.

## `test.support` — Utilities for the Python test suite

The `test.support` module provides support for Python's

regression test suite.

## Note

`test.support` is not a public module. It is documented here to help Python developers write tests. The API of this module is subject to change without backwards compatibility concerns between releases.

This module defines the following exceptions:

*exception* `test.support.TestFailed`

Exception to be raised when a test fails. This is deprecated in favor of `unittest`-based tests and `unittest.TestCase`'s assertion methods.

*exception* `test.support.ResourceDenied`

Subclass of `unittest.SkipTest`. Raised when a resource (such as a network connection) is not available. Raised by the `requires()` function.

The `test.support` module defines the following constants:

`test.support.verbose`

`True` when verbose output is enabled. Should be checked when more detailed information is desired about a running test. `verbose` is set by `test.regrtest`.

`test.support.is_jython`

`True` if the running interpreter is Jython.

`test.support.is_android`

`True` if the system is Android.

`test.support.unix_shell`

Path for shell if not on Windows; otherwise `None`.

`test.support.LOOPBACK_TIMEOUT`

Timeout in seconds for tests using a network server listening on the network local loopback interface like `127.0.0.1`.

The timeout is long enough to prevent test failure: it takes into account that the client and the server can run in different threads or even different processes.

The timeout should be long enough for `connect()`, `recv()` and `send()` methods of `socket.socket`.

Its default value is 5 seconds.

See also `INTERNET_TIMEOUT`.

#### `test.support.INTERNET_TIMEOUT`

Timeout in seconds for network requests going to the internet.

The timeout is short enough to prevent a test to wait for too long if the internet request is blocked for whatever reason.

Usually, a timeout using `INTERNET_TIMEOUT` should not mark a test as failed, but skip the test instead: see `transient_internet()`.

Its default value is 1 minute.

See also `LOOPBACK_TIMEOUT`.

#### `test.support.SHORT_TIMEOUT`

Timeout in seconds to mark a test as failed if the test takes “too long”.

The timeout value depends on the `regtest --timeout` command line option.

If a test using `SHORT_TIMEOUT` starts to fail randomly on slow buildbots, use `LONG_TIMEOUT` instead.

Its default value is 30 seconds.

`test.support.LONG_TIMEOUT`

Timeout in seconds to detect when a test hangs.

It is long enough to reduce the risk of test failure on the slowest Python buildbots. It should not be used to mark a test as failed if the test takes “too long”. The timeout value depends on the `regtest --timeout` command line option.

Its default value is 5 minutes.

See also [LOOPBACK\\_TIMEOUT](#), [INTERNET\\_TIMEOUT](#) and [SHORT\\_TIMEOUT](#).

`test.support.PGO`

Set when tests can be skipped when they are not useful for PGO.

`test.support.PIPE_MAX_SIZE`

A constant that is likely larger than the underlying OS pipe buffer size, to make writes blocking.

`test.support.Py_DEBUG`

True if Python is built with the `Py_DEBUG` macro defined: if Python is [built in debug mode](#) (`./configure --with-pydebug`).

*New in version 3.12.*

`test.support.SOCK_MAX_SIZE`

A constant that is likely larger than the underlying OS socket buffer size, to make writes blocking.

`test.support.TEST_SUPPORT_DIR`

Set to the top level directory that contains [test.support](#).

`test.support.TEST_HOME_DIR`

Set to the top level directory for the test package.

`test.support.TEST_DATA_DIR`

Set to the `data` directory within the test package.

`test.support.MAX_Py_ssize_t`

Set to `sys.maxsize` for big memory tests.

`test.support.max_memuse`

Set by `set_memlimit()` as the memory limit for big memory tests. Limited by `MAX_Py_ssize_t`.

`test.support.real_max_memuse`

Set by `set_memlimit()` as the memory limit for big memory tests. Not limited by `MAX_Py_ssize_t`.

`test.support.MISSING_C_DOCSTRINGS`

Set to `True` if Python is built without docstrings (the `WITH_DOC_STRINGS` macro is not defined). See the `configure --without-doc-strings` option.

See also the `HAVE_DOCSTRINGS` variable.

`test.support.HAVE_DOCSTRINGS`

Set to `True` if function docstrings are available. See the `python -OO` option, which strips docstrings of functions implemented in Python.

See also the `MISSING_C_DOCSTRINGS` variable.

`test.support.TEST_HTTP_URL`

Define the URL of a dedicated HTTP server for the network tests.

`test.support.ALWAYS_EQ`

Object that is equal to anything. Used to test mixed type comparison.

`test.support.NEVER_EQ`

Object that is not equal to anything (even to `ALWAYS_EQ`).  
Used to test mixed type comparison.

`test.support.LARGEST`

Object that is greater than anything (except itself). Used to test mixed type comparison.

`test.support.SMALLEST`

Object that is less than anything (except itself). Used to test mixed type comparison.

The `test.support` module defines the following functions:

`test.support.busy_retry(timeout, err_msg=None, /, *, error=True)`

Run the loop body until `break` stops the loop.

After *timeout* seconds, raise an `AssertionError` if *error* is true, or just stop the loop if *error* is false.

Example:

```
for _ in support.busy_retry(support.SHORT_TIMEOUT):
    if check():
        break
```

Example of `error=False` usage:

```
for _ in support.busy_retry(support.SHORT_TIMEOUT,
    if check():
        break
else:
    raise RuntimeError('my custom error')
```

`test.support.sleeping_retry(timeout, err_msg=None, /, *,  
init_delay=0.010, max_delay=1.0, error=True)`

Wait strategy that applies exponential backoff.

Run the loop body until `break` stops the loop. Sleep at each loop iteration, but not at the first iteration. The sleep delay is

doubled at each iteration (up to *max\_delay* seconds).

See [busy\\_retry\(\)](#) documentation for the parameters usage.

Example raising an exception after `SHORT_TIMEOUT` seconds:

```
for _ in support.sleeping_retry(support.SHORT_TIMEOUT):
    if check():
        break
```

Example of `error=False` usage:

```
for _ in support.sleeping_retry(support.SHORT_TIMEOUT):
    if check():
        break
else:
    raise RuntimeError('my custom error')
```

`test.support.is_resource_enabled(resource)`

Return `True` if *resource* is enabled and available. The list of available resources is only set when `test.regrtest` is executing the tests.

`test.support.python_is_optimized()`

Return `True` if Python was not built with `-O0` or `-Og`.

`test.support.with_pymalloc()`

Return `_testcapi.WITH_PYMALLOC`.

`test.support.requires(resource, msg=None)`

Raise [ResourceDenied](#) if *resource* is not available. *msg* is the argument to [ResourceDenied](#) if it is raised. Always returns `True` if called by a function whose `__name__` is `'__main__'`. Used when tests are executed by `test.regrtest`.

`test.support.sortdict(dict)`

Return a repr of *dict* with keys sorted.

`test.support.findfile(filename, subdir=None)`

Return the path to the file named *filename*. If no match is found *filename* is returned. This does not equal a failure since it could be the path to the file.

Setting *subdir* indicates a relative path to use to find the file rather than looking directly in the path directories.

`test.support.match_test(test)`

Determine whether *test* matches the patterns set in `set_match_tests()`.

`test.support.set_match_tests(accept_patterns=None,  
ignore_patterns=None)`

Define match patterns on test filenames and test method names for filtering tests.

`test.support.run_unittest(*classes)`

Execute `unittest.TestCase` subclasses passed to the function. The function scans the classes for methods starting with the prefix `test_` and executes the tests individually.

It is also legal to pass strings as parameters; these should be keys in `sys.modules`. Each associated module will be scanned by `unittest.TestLoader.loadTestsFromModule()`. This is usually seen in the following `test_main()` function:

```
def test_main():  
    support.run_unittest(__name__)
```

This will run all tests defined in the named module.

`test.support.run_doctest(module, verbosity=None, optionflags=0)`

Run `doctest.testmod()` on the given *module*. Return (failure\_count, test\_count).

If *verbosity* is `None`, `doctest.testmod()` is run with verbosity set to `verbose`. Otherwise, it is run with verbosity set to `None`. *optionflags* is passed as `optionflags` to `doctest.testmod()`.

`test.support.get_pagesize()`

Get size of a page in bytes.

*New in version 3.12.*

`test.support.setswitchinterval(interval)`

Set the `sys.setswitchinterval()` to the given *interval*. Defines a minimum interval for Android systems to prevent the system from hanging.

`test.support.check_impl_detail(**guards)`

Use this check to guard CPython's implementation-specific tests or to run them only on the implementations guarded by the arguments. This function returns `True` or `False` depending on the host platform. Example usage:

```
check_impl_detail()           # Only on CPython
check_impl_detail(jython=True) # Only on Jython.
check_impl_detail(cpython=False) # Everywhere except Jython
```

`test.support.set_memlimit(limit)`

Set the values for `max_memuse` and `real_max_memuse` for big memory tests.

`test.support.record_original_stdout(stdout)`

Store the value from *stdout*. It is meant to hold the stdout at the time the regrtest began.

`test.support.get_original_stdout()`

Return the original stdout set by `record_original_stdout()` or `sys.stdout` if it's not set.

`test.support.args_from_interpreter_flags()`

Return a list of command line arguments reproducing the current settings in `sys.flags` and `sys.warnoptions`.

`test.support.optim_args_from_interpreter_flags()`

Return a list of command line arguments reproducing the current optimization settings in `sys.flags`.

`test.support.captured_stdin()`

`test.support.captured_stdout()`

`test.support.captured_stderr()`

A context managers that temporarily replaces the named stream with `io.StringIO` object.

Example use with output streams:

```
with captured_stdout() as stdout, captured_stderr():
    print("hello")
    print("error", file=sys.stderr)
assert stdout.getvalue() == "hello\n"
assert stderr.getvalue() == "error\n"
```

Example use with input stream:

```
with captured_stdin() as stdin:
    stdin.write('hello\n')
    stdin.seek(0)
    # call test code that consumes from sys.stdin
    captured = input()
self.assertEqual(captured, "hello")
```

`test.support.disable_faulthandler()`

A context manager that temporary disables `faulthandler`.

`test.support.gc_collect()`

Force as many objects as possible to be collected. This is needed because timely deallocation is not guaranteed by the garbage collector. This means that `__del__` methods may be called later than expected and weakrefs may remain alive for longer than expected.

`test.support.disable_gc()`

A context manager that disables the garbage collector on entry. On exit, the garbage collector is restored to its prior state.

`test.support.swap_attr(obj, attr, new_val)`

Context manager to swap out an attribute with a new object.

Usage:

```
with swap_attr(obj, "attr", 5):  
    ...
```

This will set `obj.attr` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `attr` doesn't exist on `obj`, it will be created and then deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the “as” clause, if there is one.

`test.support.swap_item(obj, attr, new_val)`

Context manager to swap out an item with a new object.

Usage:

```
with swap_item(obj, "item", 5):  
    ...
```

This will set `obj["item"]` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `item` doesn't exist on `obj`, it will be created and then

deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the “as” clause, if there is one.

`test.support.flush_std_streams()`

Call the `flush()` method on `sys.stdout` and then on `sys.stderr`. It can be used to make sure that the logs order is consistent before writing into `stderr`.

*New in version 3.11.*

`test.support.print_warning(msg)`

Print a warning into `sys.__stderr__`. Format the message as: `f"Warning -- {msg}"`. If `msg` is made of multiple lines, add `"Warning -- "` prefix to each line.

*New in version 3.9.*

`test.support.wait_process(pid, *, exitcode, timeout=None)`

Wait until process `pid` completes and check that the process exit code is `exitcode`.

Raise an `AssertionError` if the process exit code is not equal to `exitcode`.

If the process runs longer than `timeout` seconds (`SHORT_TIMEOUT` by default), kill the process and raise an `AssertionError`. The timeout feature is not available on Windows.

*New in version 3.9.*

`test.support.calcobjsize(fmt)`

Return the size of the `PyObject` whose structure members are defined by `fmt`. The returned value includes the size of the Python object header and alignment.

`test.support.calcvobysize(fmt)`

Return the size of the `PyVarObject` whose structure members are defined by *fmt*. The returned value includes the size of the Python object header and alignment.

`test.support.checksizeof(test, o, size)`

For testcase *test*, assert that the `sys.getsizeof` for *o* plus the GC header size equals *size*.

`@test.support.anticipate_failure(condition)`

A decorator to conditionally mark tests with `unittest.expectedFailure()`. Any use of this decorator should have an associated comment identifying the relevant tracker issue.

`test.support.system_must_validate_cert(f)`

A decorator that skips the decorated test on TLS certification validation failures.

`@test.support.run_with_locale(catstr, *locales)`

A decorator for running a function in a different locale, correctly resetting it after it has finished. *catstr* is the locale category as a string (for example "LC\_ALL"). The *locales* passed will be tried sequentially, and the first valid locale will be used.

`@test.support.run_with_tz(tz)`

A decorator for running a function in a specific timezone, correctly resetting it after it has finished.

`@test.support.requires_freebsd_version(*min_version)`

Decorator for the minimum version when running test on FreeBSD. If the FreeBSD version is less than the minimum, the test is skipped.

`@test.support.requires_linux_version(*min_version)`

Decorator for the minimum version when running test on Linux. If the Linux version is less than the minimum, the test is skipped.

`@test.support.requires_mac_version(*min_version)`

Decorator for the minimum version when running test on macOS. If the macOS version is less than the minimum, the test is skipped.

`@test.support.requires_IEEE_754`

Decorator for skipping tests on non-IEEE 754 platforms.

`@test.support.requires_zlib`

Decorator for skipping tests if `zlib` doesn't exist.

`@test.support.requires_gzip`

Decorator for skipping tests if `gzip` doesn't exist.

`@test.support.requires_bz2`

Decorator for skipping tests if `bz2` doesn't exist.

`@test.support.requires_lzma`

Decorator for skipping tests if `lzma` doesn't exist.

`@test.support.requires_resource(resource)`

Decorator for skipping tests if *resource* is not available.

`@test.support.requires_docstrings`

Decorator for only running the test if `HAVE_DOCSTRINGS`.

`@test.support.requires_limited_api`

Decorator for only running the test if `Limited C API` is available.

`@test.support.cpython_only`

Decorator for tests only applicable to CPython.

`@test.support.impl_detail(msg=None, **guards)`

Decorator for invoking `check_impl_detail()` on *guards*. If that returns `False`, then uses *msg* as the reason for skipping the test.

`@test.support.no_tracing`

Decorator to temporarily turn off tracing for the duration of the test.

`@test.support.refcount_test`

Decorator for tests which involve reference counting. The decorator does not run the test if it is not run by CPython. Any trace function is unset for the duration of the test to prevent unexpected refcounts caused by the trace function.

`@test.support.bigmemtest(size, memuse, dry_run=True)`

Decorator for bigmem tests.

*size* is a requested size for the test (in arbitrary, test-interpreted units.) *memuse* is the number of bytes per unit for the test, or a good estimate of it. For example, a test that needs two byte buffers, of 4 GiB each, could be decorated with `@bigmemtest(size=_4G, memuse=2)`.

The *size* argument is normally passed to the decorated test method as an extra argument. If *dry\_run* is `True`, the value passed to the test method may be less than the requested value. If *dry\_run* is `False`, it means the test doesn't support dummy runs when `-M` is not specified.

`@test.support.bigaddrspace_test`

Decorator for tests that fill the address space.

`test.support.check_syntax_error(testcase, statement, errtext=" ", *, lineno=None, offset=None)`

Test for syntax errors in *statement* by attempting to compile *statement*. *testcase* is the `unittest` instance for the test.

*errtext* is the regular expression which should match the string representation of the raised **SyntaxError**. If *lineno* is not *None*, compares to the line of the exception. If *offset* is not *None*, compares to the offset of the exception.

`test.support.open_urlresource(url, *args, **kw)`

Open *url*. If open fails, raises **TestFailed**.

`test.support.reap_children()`

Use this at the end of `test_main` whenever sub-processes are started. This will help ensure that no extra children (zombies) stick around to hog resources and create problems when looking for refleaks.

`test.support.get_attribute(obj, name)`

Get an attribute, raising **unittest.SkipTest** if **AttributeError** is raised.

`test.support.catch_unraisable_exception()`

Context manager catching unraisable exception using **sys.unraisablehook()**.

Storing the exception value (`cm.unraisable.exc_value`) creates a reference cycle. The reference cycle is broken explicitly when the context manager exits.

Storing the object (`cm.unraisable.object`) can resurrect it if it is set to an object which is being finalized. Exiting the context manager clears the stored object.

Usage:

```
with support.catch_unraisable_exception() as cm:
    # code creating an "unraisable exception"
    ...

    # check the unraisable exception: use cm.unrais
    ...
```

```
# cm.unraisable attribute no longer exists at this
# (to break a reference cycle)
```

*New in version 3.8.*

`test.support.load_package_tests(pkg_dir, loader, standard_tests, pattern)`

Generic implementation of the `unittest` `load_tests` protocol for use in test packages. `pkg_dir` is the root directory of the package; `loader`, `standard_tests`, and `pattern` are the arguments expected by `load_tests`. In simple cases, the test package's `__init__.py` can be the following:

```
import os
from test.support import load_package_tests

def load_tests(*args):
    return load_package_tests(os.path.dirname(__file__),
```

`test.support.detect_api_mismatch(ref_api, other_api, *, ignore=())`

Returns the set of attributes, functions or methods of `ref_api` not found on `other_api`, except for a defined list of items to be ignored in this check specified in `ignore`.

By default this skips private attributes beginning with `'_'` but includes all magic methods, i.e. those starting and ending in `'_'`.

*New in version 3.5.*

`test.support.patch(test_instance, object_to_patch, attr_name, new_value)`

Override `object_to_patch.attr_name` with `new_value`. Also add cleanup procedure to `test_instance` to restore `object_to_patch` for `attr_name`. The `attr_name` should be a valid attribute for `object_to_patch`.

`test.support.run_in_subinterp(code)`

Run *code* in subinterpreter. Raise `unittest.SkipTest` if `tracemalloc` is enabled.

`test.support.check_free_after_iterating(test, iter, cls, args = ())`

Assert instances of *cls* are deallocated after iterating.

`test.support.missing_compiler_executable(cmd_names = [])`

Check for the existence of the compiler executables whose names are listed in *cmd\_names* or all the compiler executables when *cmd\_names* is empty and return the first missing executable or `None` when none is found missing.

`test.support.check_all_(test_case, module, name_of_module = None, extra = (), not_exported = ())`

Assert that the `__all__` variable of *module* contains all public names.

The module's public names (its API) are detected automatically based on whether they match the public name convention and were defined in *module*.

The *name\_of\_module* argument can specify (as a string or tuple thereof) what module(s) an API could be defined in order to be detected as a public API. One case for this is when *module* imports part of its public API from other modules, possibly a C backend (like `csv` and its `_csv`).

The *extra* argument can be a set of names that wouldn't otherwise be automatically detected as "public", like objects without a proper `__module__` attribute. If provided, it will be added to the automatically detected ones.

The *not\_exported* argument can be a set of names that must not be treated as part of the public API even though their names indicate otherwise.

Example use:

```
import bar
```

```

import foo
import unittest
from test import support

class MiscTestCase(unittest.TestCase):
    def test__all__(self):
        support.check__all__(self, foo)

class OtherTestCase(unittest.TestCase):
    def test__all__(self):
        extra = {'BAR_CONST', 'FOO_CONST'}
        not_exported = {'baz'} # Undocumented name
        # bar imports part of its API from _bar.
        support.check__all__(self, bar, ('bar', '_b
                                extra=extra, not_expor

```

*New in version 3.6.*

`test.support.skip_if_broken_multiprocessing_synchronize()`

Skip tests if the **multiprocessing.synchronize** module is missing, if there is no available semaphore implementation, or if creating a lock raises an **OSError**.

*New in version 3.10.*

`test.support.check_disallow_instantiation(test_case, tp, *args, **kwds)`

Assert that type *tp* cannot be instantiated using *args* and *kwds*.

*New in version 3.10.*

`test.support.adjust_int_max_str_digits(max_digits)`

This function returns a context manager that will change the global **sys.set\_int\_max\_str\_digits()** setting for the duration of the context to allow execution of test code that needs a different limit on the number of digits when converting between an integer and string.

*New in version 3.11.*

The `test.support` module defines the following classes:

*class* `test.support.SuppressCrashReport`

A context manager used to try to prevent crash dialog popups on tests that are expected to crash a subprocess.

On Windows, it disables Windows Error Reporting dialogs using `SetErrorMode` [<https://msdn.microsoft.com/en-us/library/windows/desktop/ms680621.aspx>].

On UNIX, `resource.setrlimit()` is used to set `resource.RLIMIT_CORE`'s soft limit to 0 to prevent coredump file creation.

On both platforms, the old value is restored by `__exit__()`.

*class* `test.support.SaveSignals`

Class to save and restore signal handlers registered by the Python signal handler.

`save(self)`

Save the signal handlers to a dictionary mapping signal numbers to the current signal handler.

`restore(self)`

Set the signal numbers from the `save()` dictionary to the saved handler.

*class* `test.support.Matcher`

`matches(self, d, **kwargs)`

Try to match a single dict with the supplied arguments.

`match_value(self, k, dv, v)`

Try to match a single stored value (`dv`) with a supplied value (`v`).

# test.support.socket\_helper

## — Utilities for socket tests

The `test.support.socket_helper` module provides support for socket tests.

*New in version 3.9.*

`test.support.socket_helper.IPV6_ENABLED`

Set to `True` if IPv6 is enabled on this host, `False` otherwise.

`test.support.socket_helper.find_unused_port(family=socket.AF_INET, socktype=socket.SOCK_STREAM)`

Returns an unused port that should be suitable for binding. This is achieved by creating a temporary socket with the same family and type as the `sock` parameter (default is `AF_INET`, `SOCK_STREAM`), and binding it to the specified host address (defaults to `0.0.0.0`) with the port set to 0, eliciting an unused ephemeral port from the OS. The temporary socket is then closed and deleted, and the ephemeral port is returned.

Either this method or `bind_port()` should be used for any tests where a server socket needs to be bound to a particular port for the duration of the test. Which one to use depends on whether the calling code is creating a Python socket, or if an unused port needs to be provided in a constructor or passed to an external program (i.e. the `-accept` argument to openssl's `s_server` mode). Always prefer `bind_port()` over `find_unused_port()` where possible. Using a hard coded port is discouraged since it can make multiple instances of the test impossible to run simultaneously, which is a problem for buildbots.

`test.support.socket_helper.bind_port(sock, host=HOST)`

Bind the socket to a free port and return the port number.

Relies on ephemeral ports in order to ensure we are using an unbound port. This is important as many tests may be running simultaneously, especially in a buildbot environment. This method raises an exception if the `sock.family` is `AF_INET` and `sock.type` is `SOCK_STREAM`, and the socket has `SO_REUSEADDR` or `SO_REUSEPORT` set on it. Tests should never set these socket options for TCP/IP sockets. The only case for setting these options is testing multicasting via multiple UDP sockets.

Additionally, if the `SO_EXCLUSIVEADDRUSE` socket option is available (i.e. on Windows), it will be set on the socket. This will prevent anyone else from binding to our host/port for the duration of the test.

`test.support.socket_helper.bind_unix_socket(sock, addr)`

Bind a Unix socket, raising `unittest.SkipTest` if `PermissionError` is raised.

`@test.support.socket_helper.skip_unless_bind_unix_socket`

A decorator for running tests that require a functional `bind()` for Unix sockets.

`test.support.socket_helper.transient_internet(resource_name, *, timeout=30.0, errnos=())`

A context manager that raises `ResourceDenied` when various issues with the internet connection manifest themselves as exceptions.

## `test.support.script_helper` — Utilities for the Python execution tests

The `test.support.script_helper` module provides support for Python's script execution tests.

`test.support.script_helper.interpreter_requires_environment()`

Return `True` if `sys.executable` interpreter requires environment variables in order to be able to run at all.

This is designed to be used with `@unittest.skipIf()` to annotate tests that need to use an `assert_python*`() function to launch an isolated mode (`-I`) or no environment mode (`-E`) sub-interpreter process.

A normal build & test does not run into this situation but it can happen when trying to run the standard library test suite from an interpreter that doesn't have an obvious home with Python's current home finding logic.

Setting `PYTHONHOME` is one way to get most of the testsuite to run in that situation. `PYTHONPATH` or `PYTHONUSERSITE` are other common environment variables that might impact whether or not the interpreter can start.

`test.support.script_helper.run_python_until_end(*args, **env_vars)`

Set up the environment based on `env_vars` for running the interpreter in a subprocess. The values can include `__isolated`, `__cleanenv`, `__cwd`, and `TERM`.

*Changed in version 3.9:* The function no longer strips whitespaces from `stderr`.

`test.support.script_helper.assert_python_ok(*args, **env_vars)`

Assert that running the interpreter with `args` and optional environment variables `env_vars` succeeds (`rc == 0`) and return a (return code, stdout, stderr) tuple.

If the `_cleanenv` keyword-only parameter is set, `env_vars` is used as a fresh environment.

Python is started in isolated mode (command line option `-I`), except if the `_isolated` keyword-only parameter is set to

False.

*Changed in version 3.9:* The function no longer strips whitespaces from *stderr*.

`test.support.script_helper.assert_python_failure(*args, **env_vars)`

Assert that running the interpreter with *args* and optional environment variables *env\_vars* fails (`rc != 0`) and return a (return code, stdout, stderr) tuple.

See `assert_python_ok()` for more options.

*Changed in version 3.9:* The function no longer strips whitespaces from *stderr*.

`test.support.script_helper.spawn_python(*args,  
stdout=subprocess.PIPE, stderr=subprocess.STDOUT, **kw)`

Run a Python subprocess with the given arguments.

*kw* is extra keyword args to pass to `subprocess.Popen()`. Returns a `subprocess.Popen` object.

`test.support.script_helper.kill_python(p)`

Run the given `subprocess.Popen` process until completion and return stdout.

`test.support.script_helper.make_script(script_dir, script_basename,  
source, omit_suffix=False)`

Create script containing *source* in path *script\_dir* and *script\_basename*. If *omit\_suffix* is `False`, append `.py` to the name. Return the full script path.

`test.support.script_helper.make_zip_script(zip_dir, zip_basename,  
script_name, name_in_zip=None)`

Create zip file at *zip\_dir* and *zip\_basename* with extension `zip` which contains the files in *script\_name*. *name\_in\_zip* is the archive name. Return a tuple containing (full path,

full path of archive name).

`test.support.script_helper.make_pkg(pkg_dir, init_source="")`

Create a directory named *pkg\_dir* containing an `__init__` file with *init\_source* as its contents.

`test.support.script_helper.make_zip_pkg(zip_dir, zip_basename, pkg_name, script_basename, source, depth=1, compiled=False)`

Create a zip package directory with a path of *zip\_dir* and *zip\_basename* containing an empty `__init__` file and a file *script\_basename* containing the *source*. If *compiled* is `True`, both source files will be compiled and added to the zip package. Return a tuple of the full zip path and the archive name for the zip file.

## `test.support.bytecode_helper` — Support tools for testing correct bytecode generation

The `test.support.bytecode_helper` module provides support for testing and inspecting bytecode generation.

*New in version 3.9.*

The module defines the following class:

*class*

`test.support.bytecode_helper.BytecodeTestCase(unittest.TestCase)`

This class has custom assertion methods for inspecting bytecode.

`BytecodeTestCase.get_disassembly_as_string(co)`

Return the disassembly of *co* as string.

`BytecodeTestCase.assertInBytecode(x, opname,  
argval=_UNSPECIFIED)`

Return `instr` if `opname` is found, otherwise throws  
`AssertionError`.

`BytecodeTestCase.assertNotInBytecode(x, opname,  
argval=_UNSPECIFIED)`

Throws `AssertionError` if `opname` is found.

## `test.support.threading_helper` — Utilities for threading tests

The `test.support.threading_helper` module provides support for threading tests.

*New in version 3.10.*

`test.support.threading_helper.join_thread(thread, timeout=None)`

Join a `thread` within `timeout`. Raise an `AssertionError` if thread is still alive after `timeout` seconds.

`@test.support.threading_helper.reap_threads`

Decorator to ensure the threads are cleaned up even if the test fails.

`test.support.threading_helper.start_threads(threads, unlock=None)`

Context manager to start `threads`, which is a sequence of threads. `unlock` is a function called after the threads are started, even if an exception was raised; an example would be `threading.Event.set()`. `start_threads` will attempt to join the started threads upon exit.

`test.support.threading_helper.threading_cleanup(*original_values)`

Cleanup up threads not specified in *original\_values*. Designed to emit a warning if a test leaves running threads in the background.

`test.support.threading_helper.threading_setup()`

Return current thread count and copy of dangling threads.

`test.support.threading_helper.wait_threads_exit(timeout=None)`

Context manager to wait until all threads created in the `with` statement exit.

`test.support.threading_helper.catch_threading_exception()`

Context manager catching `threading.Thread` exception using `threading.excepthook()`.

Attributes set when an exception is caught:

- `exc_type`
- `exc_value`
- `exc_traceback`
- `thread`

See `threading.excepthook()` documentation.

These attributes are deleted at the context manager exit.

Usage:

```
with threading_helper.catch_threading_exception() as cm:
    # code spawning a thread which raises an exception
    ...

    # check the thread exception, use cm attributes
    # exc_type, exc_value, exc_traceback, thread
    ...

# exc_type, exc_value, exc_traceback, thread attributes
# exists at this point
# (to avoid reference cycles)
```

*New in version 3.8.*

## `test.support.os_helper` — Utilities for os tests

The `test.support.os_helper` module provides support for os tests.

*New in version 3.10.*

`test.support.os_helper.FS_NONASCII`

A non-ASCII character encodable by `os.fsencode()`.

`test.support.os_helper.SAVEDCWD`

Set to `os.getcwd()`.

`test.support.os_helper.TESTFN`

Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

`test.support.os_helper.TESTFN_NONASCII`

Set to a filename containing the `FS_NONASCII` character, if it exists. This guarantees that if the filename exists, it can be encoded and decoded with the default filesystem encoding. This allows tests that require a non-ASCII filename to be easily skipped on platforms where they can't work.

`test.support.os_helper.TESTFN_UNENCODABLE`

Set to a filename (str type) that should not be able to be encoded by file system encoding in strict mode. It may be `None` if it's not possible to generate such a filename.

`test.support.os_helper.TESTFN_UNDECODABLE`

Set to a filename (bytes type) that should not be able to be decoded by file system encoding in strict mode. It may be `None` if it's not possible to generate such a filename.

`test.support.os_helper.TESTFN_UNICODE`

Set to a non-ASCII name for a temporary file.

`class test.support.os_helper.EnvironmentVarGuard`

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying `os.environ`. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

*Changed in version 3.1:* Added dictionary interface.

`class test.support.os_helper.FakePath(path)`

Simple [path-like object](#). It implements the `__fspath__()` method which just returns the `path` argument. If `path` is an exception, it will be raised in `__fspath__()`.

`EnvironmentVarGuard.set(envvar, value)`

Temporarily set the environment variable `envvar` to the value of `value`.

`EnvironmentVarGuard.unset(envvar)`

Temporarily unset the environment variable `envvar`.

`test.support.os_helper.can_symlink()`

Return `True` if the OS supports symbolic links, `False` otherwise.

`test.support.os_helper.can_xattr()`

Return `True` if the OS supports `xattr`, `False` otherwise.

`test.support.os_helper.change_cwd(path, quiet=False)`

A context manager that temporarily changes the current working directory to *path* and yields the directory.

If *quiet* is `False`, the context manager raises an exception on error. Otherwise, it issues only a warning and keeps the current working directory the same.

`test.support.os_helper.create_empty_file(filename)`

Create an empty file with *filename*. If it already exists, truncate it.

`test.support.os_helper.fd_count()`

Count the number of open file descriptors.

`test.support.os_helper.fs_is_case_insensitive(directory)`

Return `True` if the file system for *directory* is case-insensitive.

`test.support.os_helper.make_bad_fd()`

Create an invalid file descriptor by opening and closing a temporary file, and returning its descriptor.

`test.support.os_helper.rmdir(filename)`

Call `os.rmdir()` on *filename*. On Windows platforms, this is wrapped with a wait loop that checks for the existence of the file, which is needed due to antivirus programs that can hold files open and prevent deletion.

`test.support.os_helper.rmtree(path)`

Call `shutil.rmtree()` on *path* or call `os.lstat()` and `os.rmdir()` to remove a path and its contents. As with `rmdir()`, on Windows platforms this is wrapped with a wait loop that checks for the existence of the files.

`@test.support.os_helper.skip_unless_symlink`

A decorator for running tests that require support for

symbolic links.

`@test.support.os_helper.skip_unless_xattr`

A decorator for running tests that require support for `xattr`.

`test.support.os_helper.temp_cwd(name='tempcwd', quiet=False)`

A context manager that temporarily creates a new directory and changes the current working directory (CWD).

The context manager creates a temporary directory in the current directory with name *name* before temporarily changing the current working directory. If *name* is `None`, the temporary directory is created using `tempfile.mkdtemp()`.

If *quiet* is `False` and it is not possible to create or change the CWD, an error is raised. Otherwise, only a warning is raised and the original CWD is used.

`test.support.os_helper.temp_dir(path=None, quiet=False)`

A context manager that creates a temporary directory at *path* and yields the directory.

If *path* is `None`, the temporary directory is created using `tempfile.mkdtemp()`. If *quiet* is `False`, the context manager raises an exception on error. Otherwise, if *path* is specified and cannot be created, only a warning is issued.

`test.support.os_helper.temp_umask(umask)`

A context manager that temporarily sets the process umask.

`test.support.os_helper.unlink(filename)`

Call `os.unlink()` on *filename*. As with `rmdir()`, on Windows platforms, this is wrapped with a wait loop that checks for the existence of the file.

# test.support.import\_helper

## — Utilities for import tests

The `test.support.import_helper` module provides support for import tests.

*New in version 3.10.*

`test.support.import_helper.forget(module_name)`

Remove the module named *module\_name* from `sys.modules` and delete any byte-compiled files of the module.

`test.support.import_helper.import_fresh_module(name, fresh=(), blocked=(), deprecated=False)`

This function imports and returns a fresh copy of the named Python module by removing the named module from `sys.modules` before doing the import. Note that unlike `reload()`, the original module is not affected by this operation.

*fresh* is an iterable of additional module names that are also removed from the `sys.modules` cache before doing the import.

*blocked* is an iterable of module names that are replaced with `None` in the module cache during the import to ensure that attempts to import them raise `ImportError`.

The named module and any modules named in the *fresh* and *blocked* parameters are saved before starting the import and then reinserted into `sys.modules` when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if *deprecated* is `True`.

This function will raise `ImportError` if the named module cannot be imported.

Example use:

```
# Get copies of the warnings module for testing with  
# version being used by the rest of the test suite.  
# C implementation, the other is forced to use the  
# implementation  
py_warnings = import_fresh_module('warnings', block  
c_warnings = import_fresh_module('warnings', fresh=
```

*New in version 3.1.*

`test.support.import_helper.import_module(name, deprecated=False,  
*, required_on=())`

This function imports and returns the named module. Unlike a normal import, this function raises `unittest.SkipTest` if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if *deprecated* is `True`. If a module is required on a platform but optional for others, set *required\_on* to an iterable of platform prefixes which will be compared against `sys.platform`.

*New in version 3.1.*

`test.support.import_helper.modules_setup()`

Return a copy of `sys.modules`.

`test.support.import_helper.modules_cleanup(oldmodules)`

Remove modules except for *oldmodules* and encodings in order to preserve internal cache.

`test.support.import_helper.unload(name)`

Delete *name* from `sys.modules`.

`test.support.import_helper.make_legacy_pyc(source)`

Move a [PEP 3147](https://peps.python.org/pep-3147/) [https://peps.python.org/pep-3147/] / [PEP 488](#)

[<https://peps.python.org/pep-0488/>] pyc file to its legacy pyc location and return the file system path to the legacy pyc file. The *source* value is the file system path to the source file. It does not need to exist, however the PEP 3147/488 pyc file must exist.

`class test.support.import_helper.CleanImport(*module_names)`

A context manager to force import to return a new module reference. This is useful for testing module-level behaviors, such as the emission of a `DeprecationWarning` on import. Example usage:

```
with CleanImport('foo'):  
    importlib.import_module('foo')  # New reference
```

`class test.support.import_helper.DirsOnSysPath(*paths)`

A context manager to temporarily add directories to `sys.path`.

This makes a copy of `sys.path`, appends any directories given as positional arguments, then reverts `sys.path` to the copied settings when the context ends.

Note that *all* `sys.path` modifications in the body of the context manager, including replacement of the object, will be reverted at the end of the block.

## `test.support.warnings_helper` — Utilities for warnings tests

The `test.support.warnings_helper` module provides support for warnings tests.

*New in version 3.10.*

`test.support.warnings_helper.ignore_warnings(*, category)`

Suppress warnings that are instances of *category*, which must be `Warning` or a subclass. Roughly equivalent to `warnings.catch_warnings()` with `warnings.simplefilter('ignore', category=category)`. For example:

```
@warning_helper.ignore_warnings(category=Deprecatio
def test_suppress_warning():
    # do something
```

*New in version 3.8.*

`test.support.warnings_helper.check_no_resource_warning(testcase)`

Context manager to check that no `ResourceWarning` was raised. You must remove the object which may emit `ResourceWarning` before the end of the context manager.

`test.support.warnings_helper.check_syntax_warning(testcase, statement, errtext=" ", *, lineno=1, offset=None)`

Test for syntax warning in *statement* by attempting to compile *statement*. Test also that the `SyntaxWarning` is emitted only once, and that it will be converted to a `SyntaxError` when turned into error. *testcase* is the `unittest` instance for the test. *errtext* is the regular expression which should match the string representation of the emitted `SyntaxWarning` and raised `SyntaxError`. If *lineno* is not `None`, compares to the line of the warning and exception. If *offset* is not `None`, compares to the offset of the exception.

*New in version 3.8.*

`test.support.warnings_helper.check_warnings(*filters, quiet=True)`

A convenience wrapper for `warnings.catch_warnings()` that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling `warnings.catch_warnings(record=True)` with `warnings.simplefilter()` set to `always` and with the

option to automatically validate the results that are recorded.

`check_warnings` accepts 2-tuples of the form `("message regexp", WarningCategory)` as positional arguments. If one or more *filters* are provided, or if the optional keyword argument *quiet* is `False`, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set *quiet* to `True`.

If no arguments are specified, it defaults to:

```
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a **WarningRecorder** instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object's `warnings` attribute. As a convenience, the attributes of the object representing the most recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return `None`.

The recorder object also has a **`reset()`** method, which clears the warnings list.

The context manager is designed to be used like this:

```
with check_warnings(("assertion is always true", SyntaxError),
                    ("", UserWarning)):
    exec('assert (False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning was raised, `check_warnings()` would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

*Changed in version 3.2:* New optional arguments *filters* and *quiet*.

*class* test.support.warnings\_helper.WarningsRecorder

Class used to record warnings for unit tests. See documentation of [check\\_warnings\(\)](#) above for more details.

# Debugging and Profiling

These libraries help you with Python development: the debugger enables you to step through code, analyze stack frames and set breakpoints etc., and the profilers run code and give you a detailed breakdown of execution times, allowing you to identify bottlenecks in your programs. Auditing events provide visibility into runtime behaviors that would otherwise require intrusive debugging or patching.

# Audit events table

This table contains all events raised by `sys.audit()` or `PySys_Audit()` calls throughout the CPython runtime and the standard library. These calls were added in 3.8.0 or later (see [PEP 578](https://peps.python.org/pep-0578/) [https://peps.python.org/pep-0578/]).

See `sys.addaudithook()` and `PySys_AddAuditHook()` for information on handling these events.

**CPython implementation detail:** This table is generated from the CPython documentation, and may not represent events raised by other implementations. See your runtime specific documentation for actual events raised.

# bdb — Debugger framework

**Source code:** [Lib/bdb.py](https://github.com/python/cpython/tree/3.12/Lib/bdb.py) [https://github.com/python/cpython/tree/3.12/Lib/bdb.py]

---

The **bdb** module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

The following exception is defined:

*exception* **bdb.BdbQuit**

Exception raised by the **Bdb** class for quitting the debugger.

The **bdb** module also defines two classes:

*class* **bdb.Breakpoint**(*self, file, line, temporary = False, cond = None, funcname = None*)

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called **bpbynumber** and by (*file*, *line*) pairs through **bplist**. The former points to a single instance of class **Breakpoint**. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated **file name** should be in canonical form. If a **funcname** is defined, a breakpoint **hit** will be counted when the first line of that function is executed. A **conditional** breakpoint always counts a **hit**.

**Breakpoint** instances have the following methods:

**deleteMe()**

Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.

`enable()`

Mark the breakpoint as enabled.

`disable()`

Mark the breakpoint as disabled.

`bpformat()`

Return a string with all the information about the breakpoint, nicely formatted:

- Breakpoint number.
- Temporary status (del or keep).
- File/line position.
- Break condition.
- Number of times to ignore.
- Number of times hit.

*New in version 3.2.*

`bpprint(out=None)`

Print the output of `bpformat()` to the file `out`, or if it is `None`, to standard output.

**Breakpoint** instances have the following attributes:

`file`

File name of the **Breakpoint**.

`line`

Line number of the **Breakpoint** within `file`.

`temporary`

True if a **Breakpoint** at (file, line) is temporary.

cond

Condition for evaluating a **Breakpoint** at (file, line).

funcname

Function name that defines whether a **Breakpoint** is hit upon entering the function.

enabled

True if **Breakpoint** is enabled.

bpbnumber

Numeric index for a single instance of a **Breakpoint**.

bplist

Dictionary of **Breakpoint** instances indexed by (file, line) tuples.

ignore

Number of times to ignore a **Breakpoint**.

hits

Count of the number of times a **Breakpoint** has been hit.

*class* bdb.Bdb(skip=None)

The **Bdb** class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (**pdb.Pdb**) is an example.

The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

*New in version 3.1:* The *skip* argument.

The following methods of **Bdb** normally don't need to be overridden.

**canonic**(*filename*)

Return canonical form of *filename*.

For real file names, the canonical form is an operating-system-dependent, **case-normalized absolute path**. A *filename* with angle brackets, such as "<stdin>" generated in interactive mode, is returned unchanged.

**reset**()

Set the **botframe**, **stopframe**, **returnframe** and **quitting** attributes with values ready to start debugging.

**trace\_dispatch**(*frame*, *event*, *arg*)

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. *event* can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to return.
- "exception": An exception has occurred.
- "c\_call": A C function is about to be called.
- "c\_return": A C function has returned.
- "c\_exception": A C function has raised an

exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The *arg* parameter depends on the previous event.

See the documentation for `sys.settrace()` for more information on the trace function. For more information on code and frame objects, refer to [The standard type hierarchy](#).

`dispatch_line(frame)`

If the debugger should stop on the current line, invoke the `user_line()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_line()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

`dispatch_call(frame, arg)`

If the debugger should stop on this function call, invoke the `user_call()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

`dispatch_return(frame, arg)`

If the debugger should stop on this function return, invoke the `user_return()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_return()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

`dispatch_exception(frame, arg)`

If the debugger should stop at this exception, invokes the `user_exception()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_exception()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

Normally derived classes don't override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

`is_skipped_line(module_name)`

Return True if *module\_name* matches any skip pattern.

`stop_here(frame)`

Return True if *frame* is below the starting frame in the stack.

`break_here(frame)`

Return True if there is an effective breakpoint for this line.

Check whether a line or function breakpoint exists and is in effect. Delete temporary breakpoints based on information from `effective()`.

`break_anywhere(frame)`

Return True if any breakpoint exists for *frame*'s filename.

Derived classes should override these methods to gain control over debugger operation.

`user_call(frame, argument_list)`

Called from `dispatch_call()` if a break might stop

inside the called function.

`user_line(frame)`

Called from `dispatch_line()` when either `stop_here()` or `break_here()` returns `True`.

`user_return(frame, return_value)`

Called from `dispatch_return()` when `stop_here()` returns `True`.

`user_exception(frame, exc_info)`

Called from `dispatch_exception()` when `stop_here()` returns `True`.

`do_clear(arg)`

Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

`set_step()`

Stop after one line of code.

`set_next(frame)`

Stop on the next line in or below the given frame.

`set_return(frame)`

Stop when returning from the given frame.

`set_until(frame, lineno = None)`

Stop when the line with the *lineno* greater than the current one is reached or when returning from current frame.

`set_trace([frame])`

Start debugging from *frame*. If *frame* is not specified, debugging starts from caller's frame.

`set_continue()`

Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to `None`.

`set_quit()`

Set the **quitting** attribute to `True`. This raises **BdbQuit** in the next call to one of the **dispatch\_\*()** methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or `None` if all is well.

`set_break(filename, lineno, temporary=False, cond=None, funcname=None)`

Set a new breakpoint. If the *lineno* line doesn't exist for the *filename* passed as argument, return an error message. The *filename* should be in canonical form, as described in the **canonic()** method.

`clear_break(filename, lineno)`

Delete the breakpoints in *filename* and *lineno*. If none were set, return an error message.

`clear_bpbynumber(arg)`

Delete the breakpoint which has the index *arg* in the **Breakpoint.bpbynumber**. If *arg* is not numeric or out of range, return an error message.

`clear_all_file_breaks(filename)`

Delete all breakpoints in *filename*. If none were set,

return an error message.

`clear_all_breaks()`

Delete all existing breakpoints. If none were set, return an error message.

`get_bpbynumber(arg)`

Return a breakpoint specified by the given number. If *arg* is a string, it will be converted to a number. If *arg* is a non-numeric string, if the given breakpoint never existed or has been deleted, a `ValueError` is raised.

*New in version 3.2.*

`get_break(filename, lineno)`

Return True if there is a breakpoint for *lineno* in *filename*.

`get_breaks(filename, lineno)`

Return all breakpoints for *lineno* in *filename*, or an empty list if none are set.

`get_file_breaks(filename)`

Return all breakpoints in *filename*, or an empty list if none are set.

`get_all_breaks()`

Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

`get_stack(f, t)`

Return a list of (frame, lineno) tuples in a stack trace, and a size.

The most recently called frame is last in the list. The

size is the number of frames below the frame where the debugger was invoked.

`format_stack_entry(frame_lineno, lprefix=':')`

Return a string with information about a stack entry, which is a `(frame, lineno)` tuple. The return string contains:

- The canonical filename which contains the frame.
- The function name or "`<lambda>`".
- The input arguments.
- The return value.
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a [statement](#), given as a string.

`run(cmd, globals=None, locals=None)`

Debug a statement executed via the [exec\(\)](#) function. `globals` defaults to `__main__.__dict__`, `locals` defaults to `globals`.

`runeval(expr, globals=None, locals=None)`

Debug an expression executed via the [eval\(\)](#) function. `globals` and `locals` have the same meaning as in [run\(\)](#).

`runtcx(cmd, globals, locals)`

For backwards compatibility. Calls the [run\(\)](#) method.

`runcall(func, /, *args, **kws)`

Debug a single function call, and return its result.

Finally, the module defines the following functions:

`bdb.checkfuncname(b, frame)`

Return True if we should break here, depending on the way

the **Breakpoint** *b* was set.

If it was set via line number, it checks if **b.line** is the same as the one in *frame*. If the breakpoint was set via **function name**, we have to check we are in the right *frame* (the right function) and if we are on its first executable line.

**bdb.effective(*file, line, frame*)**

Return (active breakpoint, delete temporary flag) or (None, None) as the breakpoint to act upon.

The *active breakpoint* is the first entry in **bplist** for the (**file**, **line**) (which must exist) that is **enabled**, for which **checkfuncname()** is True, and that has neither a False **condition** nor positive **ignore** count. The *flag*, meaning that a temporary breakpoint should be deleted, is False only when the **cond** cannot be evaluated (in which case, **ignore** count is ignored).

If no such entry exists, then (None, None) is returned.

**bdb.set\_trace()**

Start debugging with a **Bdb** instance from caller's frame.

# faulthandler — Dump the Python traceback

*New in version 3.3.*

---

This module contains functions to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal. Call `faulthandler.enable()` to install fault handlers for the **SIGSEGV**, **SIGFPE**, **SIGABRT**, **SIGBUS**, and **SIGILL** signals. You can also enable them at startup by setting the **PYTHONFAULTHANDLER** environment variable or by using the `-x faulthandler` command line option.

The fault handler is compatible with system fault handlers like Apport or the Windows fault handler. The module uses an alternative stack for signal handlers if the `sigaltstack()` function is available. This allows it to dump the traceback even on a stack overflow.

The fault handler is called on catastrophic cases and therefore can only use signal-safe functions (e.g. it cannot allocate memory on the heap). Because of this limitation traceback dumping is minimal compared to normal Python tracebacks:

- Only ASCII is supported. The `backslashreplace` error handler is used on encoding.
- Each string is limited to 500 characters.
- Only the filename, the function name and the line number are displayed. (no source code)
- It is limited to 100 frames and 100 threads.
- The order is reversed: the most recent call is shown first.

By default, the Python traceback is written to `sys.stderr`. To see tracebacks, applications must be run in the terminal. A log file can alternatively be passed to `faulthandler.enable()`.

The module is implemented in C, so tracebacks can be dumped on a crash or when Python is deadlocked.

The [Python Development Mode](#) calls `faulthandler.enable()` at Python startup.

**See also**

**Module** [pdb](#)

Interactive source code debugger for Python programs.

**Module** [traceback](#)

Standard interface to extract, format and print stack traces of Python programs.

## Dumping the traceback

`faulthandler.dump_traceback(file=sys.stderr, all_threads=True)`

Dump the tracebacks of all threads into *file*. If *all\_threads* is `False`, dump only the current thread.

**See also**

[traceback.print\\_tb\(\)](#), which can be used to print a traceback object.

*Changed in version 3.5:* Added support for passing file descriptor to this function.

## Fault handler state

`faulthandler.enable(file=sys.stderr, all_threads=True)`

Enable the fault handler: install handlers for the **SIGSEGV**, **SIGFPE**, **SIGABRT**, **SIGBUS** and **SIGILL** signals to dump the Python traceback. If *all\_threads* is `True`, produce tracebacks for every running thread. Otherwise, dump only the current thread.

The *file* must be kept open until the fault handler is disabled: see [issue with file descriptors](#).

*Changed in version 3.5:* Added support for passing file descriptor to this function.

*Changed in version 3.6:* On Windows, a handler for Windows exception is also installed.

*Changed in version 3.10:* The dump now mentions if a garbage collector collection is running if *all\_threads* is true.

`faulthandler.disable()`

Disable the fault handler: uninstall the signal handlers installed by [enable\(\)](#).

`faulthandler.is_enabled()`

Check if the fault handler is enabled.

## Dumping the tracebacks after a timeout

`faulthandler.dump_traceback_later(timeout, repeat=False, file=sys.stderr, exit=False)`

Dump the tracebacks of all threads, after a timeout of *timeout* seconds, or every *timeout* seconds if *repeat* is `True`. If *exit* is `True`, call `_exit()` with `status=1` after dumping the tracebacks. (Note `_exit()` exits the process immediately, which means it doesn't do any cleanup like flushing file buffers.) If the function is called twice, the new call replaces previous parameters and resets the timeout. The timer has a sub-second resolution.

The *file* must be kept open until the traceback is dumped or [cancel\\_dump\\_traceback\\_later\(\)](#) is called: see [issue with file descriptors](#).

This function is implemented using a watchdog thread.

*Changed in version 3.7:* This function is now always available.

*Changed in version 3.5:* Added support for passing file descriptor to this function.

`faulthandler.cancel_dump_traceback_later()`

Cancel the last call to `dump_traceback_later()`.

## Dumping the traceback on a user signal

`faulthandler.register(signum, file=sys.stderr, all_threads=True, chain=False)`

Register a user signal: install a handler for the *signum* signal to dump the traceback of all threads, or of the current thread if *all\_threads* is `False`, into *file*. Call the previous handler if *chain* is `True`.

The *file* must be kept open until the signal is unregistered by `unregister()`: see [issue with file descriptors](#).

Not available on Windows.

*Changed in version 3.5:* Added support for passing file descriptor to this function.

`faulthandler.unregister(signum)`

Unregister a user signal: uninstall the handler of the *signum* signal installed by `register()`. Return `True` if the signal was registered, `False` otherwise.

Not available on Windows.

## Issue with file descriptors

`enable()`, `dump_traceback_later()` and `register()` keep the file descriptor of their *file* argument. If the file is closed and its file descriptor is reused by a new file, or if `os.dup2()` is used to replace the file descriptor, the traceback will be written into a different file. Call these functions again each time that the file is replaced.

# Example

Example of a segmentation fault on Linux with and without enabling the fault handler:

```
$ python -c "import ctypes; ctypes.string_at(0)"
Segmentation fault
```

```
$ python -q -X faulthandler
>>> import ctypes
>>> ctypes.string_at(0)
Fatal Python error: Segmentation fault
```

```
Current thread 0x00007fb899f39700 (most recent call first)
  File "/home/python/cpython/Lib/ctypes/__init__.py", line 1
  File "<stdin>", line 1 in <module>
Segmentation fault
```

# pdb — The Python Debugger

**Source code:** [Lib/pdb.py](https://github.com/python/cpython/tree/3.12/Lib/pdb.py) [https://github.com/python/cpython/tree/3.12/Lib/pdb.py]

---

The module `pdb` defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible – it is actually defined as the class `Pdb`. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules `bdb` and `cmd`.

## See also

### Module `faulthandler`

Used to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal.

### Module `traceback`

Standard interface to extract, format and print stack traces of Python programs.

The typical usage to break into the debugger is to insert:

```
import pdb; pdb.set_trace()
```

Or:

```
breakpoint()
```

at the location you want to break into the debugger, and then run the program. You can then step through the code following this

statement, and continue running without the debugger using the **continue** command.

*New in version 3.7:* The built-in **breakpoint()**, when called with defaults, can be used instead of `import pdb; pdb.set_trace()`.

```
def double(x):
    breakpoint()
    return x * 2
val = 3
print(f"{val} * 2 is {double(val)}")
```

The debugger's prompt is `(Pdb)`, which is the indicator that you are in debug mode:

```
> ... (3) double()
-> return x * 2
(Pdb) p x
3
(Pdb) continue
3 * 2 is 6
```

*Changed in version 3.3:* Tab-completion via the **readline** module is available for commands and command arguments, e.g. the current global and local names are offered as arguments of the `p` command.

You can also invoke **pdb** from the command line to debug other scripts. For example:

```
python -m pdb myscript.py
```

When invoked as a module, `pdb` will automatically enter post-mortem debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), `pdb` will restart the program. Automatic restarting preserves `pdb`'s state (such as breakpoints) and in most cases is more useful than quitting the debugger upon program's exit.

*New in version 3.2:* `-c` option is introduced to execute commands as

if given in a `.pdbrc` file, see [Debugger Commands](#).

**New in version 3.7:** `-m` option is introduced to execute modules similar to the way `python -m` does. As with a script, the debugger will pause execution just before the first line of the module.

Typical usage to execute a statement under control of the debugger is:

```
>>> import pdb
>>> def f(x):
...     print(1 / x)
>>> pdb.run("f(2)")
> <string>(1)<module>()
(Pdb) continue
0.5
>>>
```

The typical usage to inspect a crashed program is:

```
>>> import pdb
>>> def f(x):
...     print(1 / x)
...
>>> f(0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in f
ZeroDivisionError: division by zero
>>> pdb.pm()
> <stdin>(2)f()
(Pdb) p x
0
(Pdb)
```

The module defines the following functions; each enters the debugger in a slightly different way:

`pdb.run(statement, globals=None, locals=None)`

Execute the *statement* (given as a string or a code object)

under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type `continue`, or you can step through the statement using `step` or `next` (all these commands are explained below). The optional *globals* and *locals* arguments specify the environment in which the code is executed; by default the dictionary of the module `__main__` is used. (See the explanation of the built-in `exec()` or `eval()` functions.)

`pdb.runeval(expression, globals=None, locals=None)`

Evaluate the *expression* (given as a string or a code object) under debugger control. When `runeval()` returns, it returns the value of the *expression*. Otherwise this function is similar to `run()`.

`pdb.runcall(function, *args, **kwargs)`

Call the *function* (a function or method object, not a string) with the given arguments. When `runcall()` returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.

`pdb.set_trace(*, header=None)`

Enter the debugger at the calling stack frame. This is useful to hard-code a breakpoint at a given point in a program, even if the code is not otherwise being debugged (e.g. when an assertion fails). If given, *header* is printed to the console just before debugging begins.

*Changed in version 3.7:* The keyword-only argument *header*.

`pdb.post_mortem(traceback=None)`

Enter post-mortem debugging of the given *traceback* object. If no *traceback* is given, it uses the one of the exception that is currently being handled (an exception must be being handled if the default is to be used).

`pdb.pm()`

Enter post-mortem debugging of the traceback found in `sys.last_traceback`.

The `run*` functions and `set_trace()` are aliases for instantiating the `Pdb` class and calling the method of the same name. If you want to access further features, you have to do this yourself:

```
class pdb.Pdb(completekey='tab', stdin=None, stdout=None,
skip=None, nosigint=False, readrc=True)
```

`Pdb` is the debugger class.

The `completekey`, `stdin` and `stdout` arguments are passed to the underlying `cmd.Cmd` class; see the description there.

The `skip` argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. [1](#)

By default, `Pdb` sets a handler for the SIGINT signal (which is sent when the user presses `Ctrl-C` on the console) when you give a `continue` command. This allows you to break into the debugger again by pressing `Ctrl-C`. If you want `Pdb` not to touch the SIGINT handler, set `nosigint` to true.

The `readrc` argument defaults to true and controls whether `Pdb` will load `.pdbrc` files from the filesystem.

Example call to enable tracing with `skip`:

```
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

Raises an `auditing event` `pdb.Pdb` with no arguments.

*New in version 3.1:* The `skip` argument.

*New in version 3.2:* The `nosigint` argument. Previously, a SIGINT handler was never set by `Pdb`.

*Changed in version 3.6:* The `readrc` argument.

```
run(statement, globals=None, locals=None)
runeval(expression, globals=None, locals=None)
runcall(function, *args, **kws)
set_trace()
```

See the documentation for the functions explained above.

## Debugger Commands

The commands recognized by the debugger are listed below. Most commands can be abbreviated to one or two letters as indicated; e.g. `h(elp)` means that either `h` or `help` can be used to enter the help command (but not `he` or `hel`, nor `H` or `Help` or `HELP`). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets (`[]`) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (`|`).

Entering a blank line repeats the last command entered. Exception: if the last command was a `list` command, the next 11 lines are listed.

Commands that the debugger doesn't recognize are assumed to be Python statements and are executed in the context of the program being debugged. Python statements can also be prefixed with an exclamation point (`!`). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger's state is not changed.

The debugger supports `aliases`. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

Multiple commands may be entered on a single line, separated by `;;`. (A single `;` is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split

at the first `;;` pair, even if it is in the middle of a quoted string. A workaround for strings with double semicolons is to use implicit string concatenation `';;'` or `"";`.

To set a temporary global variable, use a *convenience variable*. A *convenience variable* is a variable whose name starts with `$`. For example, `$foo = 1` sets a global variable `$foo` which you can use in the debugger session. The *convenience variables* are cleared when the program resumes execution so it's less likely to interfere with your program compared to using normal variables like `foo = 1`.

There are three preset *convenience variables*:

- `$_frame`: the current frame you are debugging
- `$_retval`: the return value if the frame is returning
- `$_exception`: the exception if the frame is raising an exception

*New in version 3.12.*

If a file `.pdbrc` exists in the user's home directory or in the current directory, it is read with `'utf-8'` encoding and executed as if it had been typed at the debugger prompt. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

*Changed in version 3.11:* `.pdbrc` is now read with `'utf-8'` encoding. Previously, it was read with the system locale encoding.

*Changed in version 3.2:* `.pdbrc` can now contain commands that continue debugging, such as `continue` or `next`. Previously, these commands had no effect.

`h(elp) [command]`

Without argument, print the list of available commands. With a *command* as argument, print help about that command.

`help pdb` displays the full documentation (the docstring of the `pdb` module). Since the *command* argument must be an identifier, `help exec` must be entered to get help on the `!`

command.

w(here)

Print a stack trace, with the most recent frame at the bottom. An arrow (>) indicates the current frame, which determines the context of most commands.

d(own) [count]

Move the current frame *count* (default one) levels down in the stack trace (to a newer frame).

u(p) [count]

Move the current frame *count* (default one) levels up in the stack trace (to an older frame).

b(reak) [[(filename:]lineno | function) [, condition]]

With a *lineno* argument, set a break there in the current file. With a *function* argument, set a break at the first executable statement within that function. The line number may be prefixed with a filename and a colon, to specify a breakpoint in another file (probably one that hasn't been loaded yet). The file is searched on `sys.path`. Note that each breakpoint is assigned a number to which all the other breakpoint commands refer.

If a second argument is present, it is an expression which must evaluate to true before the breakpoint is honored.

Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

tbreak [[(filename:]lineno | function) [, condition]]

Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as for `break`.

cl(ear) [filename:lineno | bpnumber ...]

With a *filename:lineno* argument, clear all the breakpoints at

this line. With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

`disable bnumber [bnumber ...]`

Disable the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

`enable bnumber [bnumber ...]`

Enable the breakpoints specified.

`ignore bnumber [count]`

Set the ignore count for the given breakpoint number. If *count* is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the *count* is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

`condition bnumber [condition]`

Set a new *condition* for the breakpoint, an expression which must evaluate to true before the breakpoint is honored. If *condition* is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

`commands [bnumber]`

Specify a list of commands for breakpoint number *bnumber*. The commands themselves appear on the following lines. Type a line containing just `end` to terminate the commands. An example:

```
(Pdb) commands 1
(com) p some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type `commands` and follow it immediately with `end`; that is, give no commands.

With no *bpnumber* argument, `commands` refers to the last breakpoint set.

You can use breakpoint commands to start your program up again. Simply use the `continue` command, or `step`, or any other command that resumes execution.

Specifying any command resuming execution (currently `continue`, `step`, `next`, `return`, `jump`, `quit` and their abbreviations) terminates the command list (as if that command was immediately followed by `end`). This is because any time you resume execution (even with a simple `next` or `step`), you may encounter another breakpoint—which could have its own command list, leading to ambiguities about which list to execute.

If you use the `silent` command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

`s(tep)`

Execute the current line, stop at the first possible occasion (either in a function that is called or on the next line in the current function).

`n(ext)`

Continue execution until the next line in the current function is reached or it returns. (The difference between `next` and `step` is that `step` stops inside a called function, while `next` executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

`unt(il) [lineno]`

Without argument, continue execution until the line with a number greater than the current one is reached.

With *lineno*, continue execution until a line with a number greater or equal to *lineno* is reached. In both cases, also stop when the current frame returns.

*Changed in version 3.2:* Allow giving an explicit line number.

`r(eturn)`

Continue execution until the current function returns.

`c(ontinue)`

Continue execution, only stop when a breakpoint is encountered.

`j(ump) lineno`

Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don't want to run.

It should be noted that not all jumps are allowed – for instance it is not possible to jump into the middle of a `for` loop or out of a `finally` clause.

`l(ist) [first[, last]]`

List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With `.` as argument, list 11 lines around the current line. With one argument, list 11 lines around at that line. With two arguments, list the given range; if the second argument is less than the first, it is interpreted as a count.

The current line in the current frame is indicated by `->`. If an exception is being debugged, the line where the exception was originally raised or propagated is indicated by `>>`, if it differs from the current line.

*New in version 3.2:* The `>>` marker.

`ll | longlist`

List all source code for the current function or frame.

Interesting lines are marked as for `list`.

*New in version 3.2.*

`a(rgs)`

Print the arguments of the current function and their current values.

`p expression`

Evaluate *expression* in the current context and print its value.

### **Note**

`print()` can also be used, but is not a debugger command — this executes the Python `print()` function.

`pp expression`

Like the `p` command, except the value of *expression* is pretty-printed using the `pprint` module.

`whatis expression`

Print the type of *expression*.

`source expression`

Try to get source code of *expression* and display it.

*New in version 3.2.*

`display [expression]`

Display the value of *expression* if it changed, each time execution stops in the current frame.

Without *expression*, list all display expressions for the current

frame.

### Note

Display evaluates *expression* and compares to the result of the previous evaluation of *expression*, so when the result is mutable, display may not be able to pick up the changes.

Example:

```
lst = []
breakpoint()
pass
lst.append(1)
print(lst)
```

Display won't realize `lst` has been changed because the result of evaluation is modified in place by `lst.append(1)` before being compared:

```
> example.py(3) <module> ()
-> pass
(Pdb) display lst
display lst: []
(Pdb) n
> example.py(4) <module> ()
-> lst.append(1)
(Pdb) n
> example.py(5) <module> ()
-> print(lst)
(Pdb)
```

You can do some tricks with copy mechanism to make it work:

```
> example.py(3) <module> ()
-> pass
(Pdb) display lst[:]
display lst[:]: []
(Pdb) n
```

```
> example.py(4)<module>()
-> lst.append(1)
(Pdb) n
> example.py(5)<module>()
-> print(lst)
display lst[:]: [1]  [old: []]
(Pdb)
```

*New in version 3.2.*

`undisplay [expression]`

Do not display *expression* anymore in the current frame. Without *expression*, clear all display expressions for the current frame.

*New in version 3.2.*

`interact`

Start an interactive interpreter (using the [code](#) module) whose global namespace contains all the (global and local) names found in the current scope.

*New in version 3.2.*

`alias [name [command]]`

Create an alias called *name* that executes *command*. The *command* must *not* be enclosed in quotes. Replaceable parameters can be indicated by `%1`, `%2`, and so on, while `%%` is replaced by all the parameters. If *command* is omitted, the current alias for *name* is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the pdb prompt. Note that internal pdb commands *can* be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.

As an example, here are two useful aliases (especially when placed in the `.pdbrc` file):

```
# Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print(f"%1.{k}")
# Print instance variables in self
alias ps pi self
```

**unalias name**

Delete the specified alias *name*.

**! statement**

Execute the (one-line) *statement* in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command, e.g.:

```
(Pdb) ! n=42
(Pdb)
```

To set a global variable, you can prefix the assignment command with a **global** statement on the same line, e.g.:

```
(Pdb) global list_options; list_options = ['-l']
(Pdb)
```

**run [args ...]**

**restart [args ...]**

Restart the debugged Python program. If *args* is supplied, it is split with **shlex** and the result is used as the new **sys.argv**. History, breakpoints, actions and debugger options are preserved. **restart** is an alias for **run**.

**q(uit)**

Quit from the debugger. The program being executed is aborted.

**debug code**

Enter a recursive debugger that steps through *code* (which is an arbitrary expression or statement to be executed in the current environment).

retval

Print the return value for the last return of the current function.

## Footnotes

1

Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

---

## Introduction to the profilers

**cProfile** and **profile** provide *deterministic profiling* of Python programs. A *profile* is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the **pstats** module.

The Python standard library provides two different implementations of the same profiling interface:

1. **cProfile** is recommended for most users; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on **lsprof**, contributed by Brett Rosen and Ted Czotter.
2. **profile**, a pure Python module whose interface is imitated by **cProfile**, but which adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Originally designed and written by Jim Roskind.

### Note

The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is **timeit** for reasonably accurate results). This particularly applies to benchmarking Python code against C code: the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.

# Instant User's Manual

This section is provided for users that “don’t want to read the manual.” It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would run `re.compile()` and print profile results like the following:

```
214 function calls (207 primitive calls) in 0.002
```

Ordered by: cumulative time

ncalls	tottime	percall	cumtime	percall	filename:line
1	0.000	0.000	0.002	0.002	{built-in method
1	0.000	0.000	0.001	0.001	<string>:1 (<m
1	0.000	0.000	0.001	0.001	__init__.py:2
1	0.000	0.000	0.001	0.001	__init__.py:2
1	0.000	0.000	0.000	0.000	_compiler.py:
1	0.000	0.000	0.000	0.000	_parser.py:93
1	0.000	0.000	0.000	0.000	_compiler.py:
1	0.000	0.000	0.000	0.000	_parser.py:43

The first line indicates that 214 calls were monitored. Of those calls, 207 were *primitive*, meaning that the call was not induced via recursion. The next line: Ordered by: cumulative time, indicates that the text string in the far right column was used to sort the output. The column headings include:

ncalls  
for the number of calls.

`tottime`

for the total time spent in the given function (and excluding time made in calls to sub-functions)

`percall`

is the quotient of `tottime` divided by `ncalls`

`cumtime`

is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate *even* for recursive functions.

`percall`

is the quotient of `cumtime` divided by primitive calls

`filename:lineno(function)`

provides the respective data of each function

When there are two numbers in the first column (for example 3/1), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the `run()` function:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")', 'restats')
```

The `pstats.Stats` class reads profile results from a file and formats them in various ways.

The files `cProfile` and `profile` can also be invoked as a script to profile another script. For example:

```
python -m cProfile [-o output_file] [-s sort_order] (-m
```

`-o` writes the profile results to a file instead of to stdout

`-s` specifies one of the `sort_stats()` sort values to sort the output by. This only applies when `-o` is not supplied.

`-m` specifies that a module is being profiled instead of a script.

*New in version 3.7:* Added the `-m` option to `cProfile`.

*New in version 3.8:* Added the `-m` option to `profile`.

The `pstats` module's `Stats` class has a variety of methods for manipulating and printing the data saved into a profile results file:

```
import pstats
from pstats import SortKey
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The `strip_dirs()` method removed the extraneous path from all the module names. The `sort_stats()` method sorted all the entries according to the standard module/line/name string that is printed. The `print_stats()` method printed out all the statistics. You might try the following sort calls:

```
p.sort_stats(SortKey.NAME)
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls to experiment with:

```
p.sort_stats(SortKey.CUMULATIVE).print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:

```
p.sort_stats(SortKey.TIME).print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try:

```
p.sort_stats(SortKey.FILENAME).print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try:

```
p.sort_stats(SortKey.TIME, SortKey.CUMULATIVE).print_stats()
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re: `.5`) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could now (`p` is still sorted according to the last criteria) do:

```
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you're going to have to read the manual, or guess what the following functions do:

```
p.print_callees()  
p.add('restats')
```

Invoked as a script, the `pstats` module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using `cmd`) and interactive help.

## **profile and cProfile Module Reference**

Both the `profile` and `cProfile` modules provide the following functions:

`profile.run(command, filename=None, sort=-1)`

This function takes a single argument that can be passed to the `exec()` function, and an optional file name. In all cases this routine executes:

```
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a `Stats` instance and prints a simple profiling report. If the sort value is specified, it is passed to this `Stats` instance to control how the results are sorted.

`profile.runtx(command, globals, locals, filename=None, sort=-1)`

This function is similar to `run()`, with added arguments to supply the globals and locals dictionaries for the `command` string. This routine executes:

```
exec(command, globals, locals)
```

and gathers profiling statistics as in the `run()` function above.

`class profile.Profile(timer=None, timeunit=0.0, subcalls=True, builtins=True)`

This class is normally only used if more precise control over profiling is needed than what the `cProfile.run()` function provides.

A custom timer can be supplied for measuring how long code takes to run via the `timer` argument. This must be a function that returns a single number representing the current time. If the number is an integer, the `timeunit` specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be `.001`.

Directly using the `Profile` class allows formatting profile results without writing the profile data to a file:

```

import cProfile, pstats, io
from pstats import SortKey
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = io.StringIO()
sortby = SortKey.CUMULATIVE
ps = pstats.Stats(pr, stream=s).sort_stats(sortby)
ps.print_stats()
print(s.getvalue())

```

The **Profile** class can also be used as a context manager (supported only in **cProfile** module. see [Context Manager Types](#)):

```

import cProfile

with cProfile.Profile() as pr:
    # ... do something ...

    pr.print_stats()

```

*Changed in version 3.8:* Added context manager support.

**enable()**

Start collecting profiling data. Only in **cProfile**.

**disable()**

Stop collecting profiling data. Only in **cProfile**.

**create\_stats()**

Stop collecting profiling data and record the results internally as the current profile.

**print\_stats(sort=-1)**

Create a **Stats** object based on the current profile and print the results to stdout.

`dump_stats(filename)`

Write the results of the current profile to *filename*.

`run(cmd)`

Profile the cmd via `exec()`.

`runcx(cmd, globals, locals)`

Profile the cmd via `exec()` with the specified global and local environment.

`runcall(func, /, *args, **kwargs)`

Profile `func(*args, **kwargs)`

Note that profiling will only work if the called command/function actually returns. If the interpreter is terminated (e.g. via a `sys.exit()` call during the called command/function execution) no profiling results will be printed.

## The Stats Class

Analysis of the profiler data is done using the `Stats` class.

`class pstats.Stats(*filenames or profile, stream=sys.stdout)`

This class constructor creates an instance of a “statistics object” from a *filename* (or list of filenames) or from a **Profile** instance. Output will be printed to the stream specified by *stream*.

The file selected by the above constructor must have been created by the corresponding version of `profile` or `cProfile`. To be specific, there is *no* file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers, or the same profiler run on a different operating system. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be

combined with data in an existing **Stats** object, the **add()** method can be used.

Instead of reading the profile data from a file, a **cProfile.Profile** or **profile.Profile** object can be used as the profile data source.

**Stats** objects have the following methods:

**strip\_dirs()**

This method for the **Stats** class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its entries in a “random” order, as it was just after object initialization and loading. If **strip\_dirs()** causes two function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

**add(\*filenames)**

This method of the **Stats** class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of **profile.run()** or **cProfile.run()**. Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

**dump\_stats(filename)**

Save the data loaded into the **Stats** object to a file named *filename*. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the **profile.Profile** and **cProfile.Profile** classes.

`sort_stats(*keys)`

This method modifies the `Stats` object by sorting it according to the supplied criteria. The argument can be either a string or a `SortKey` enum identifying the basis of a sort (example: `'time'`, `'name'`, `SortKey.TIME` or `SortKey.NAME`). The `SortKey` enums argument have advantage over the string argument in that it is more robust and less error prone.

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, `sort_stats(SortKey.NAME, SortKey.FILE)` will sort all the entries according to their function name, and resolve all ties (identical function names) by sorting by file name.

For the string argument, abbreviations can be used for any key names, as long as the abbreviation is unambiguous.

The following are the valid string and `SortKey`:

Valid string Arg
<code>SortKey.CALLS</code>
<code>SortKey.CUMULATIVE</code>
<code>SortKey.TIME</code>
<code>SortKey.NAME</code>
<code>SortKey.FILE</code>
<code>SortKey.CALLSunt</code>
<code>SortKey.LINE</code>
<code>SortKey.NAME</code>
<code>SortKey.LINE</code>
<code>SortKey.SOURCE</code>
<code>SortKey.TIME</code>
<code>SortKey.NAME</code>

Note that all sorts on statistics are in descending order

(placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between `SortKey.NFL` and `SortKey.STDNAME` is that the standard name is a sort of the name as printed, which means that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, `SortKey.NFL` does a numeric compare of the line numbers. In fact, `sort_stats(SortKey.NFL)` is the same as `sort_stats(SortKey.NAME, SortKey.FILENAME, SortKey.LINE)`.

For backward-compatibility reasons, the numeric arguments `-1`, `0`, `1`, and `2` are permitted. They are interpreted as `'stdname'`, `'calls'`, `'time'`, and `'cumulative'` respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

*New in version 3.7:* Added the `SortKey` enum.

`reverse_order()`

This method for the `Stats` class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

`print_stats(*restrictions)`

This method for the `Stats` class prints out a report as described in the `profile.run()` definition.

The order of the printing is based on the last `sort_stats()` operation done on the object (subject to caveats in `add()` and `strip_dirs()`).

The arguments provided (if any) can be used to limit

the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction between 0.0 and 1.0 inclusive (to select a percentage of lines), or a string that will interpreted as a regular expression (to pattern match the standard name that is printed). If several restrictions are provided, then they are applied sequentially. For example:

```
print_stats(.1, 'foo:')
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename `. *foo:.` In contrast, the command:

```
print_stats('foo:', .1)
```

would limit the list to all functions having file names `. *foo:`, and then proceed to only print the first 10% of them.

`print_callers(*restrictions)`

This method for the `Stats` class prints a list of all functions that called each function in the profiled database. The ordering is identical to that provided by `print_stats()`, and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats:

- With `profile`, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function at the right.
- With `cProfile`, each caller is preceded by three numbers: the number of times this specific call was made, and the total and cumulative times

spent in the current function while it was invoked by this specific caller.

`print_callees(*restrictions)`

This method for the `Stats` class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the `print_callers()` method.

`get_stats_profile()`

This method returns an instance of `StatsProfile`, which contains a mapping of function names to instances of `FunctionProfile`. Each `FunctionProfile` instance holds information related to the function's profile such as how long the function took to run, how many times it was called, etc...

*New in version 3.9:* Added the following dataclasses: `StatsProfile`, `FunctionProfile`. Added the following function: `get_stats_profile`.

## What Is Deterministic Profiling?

*Deterministic profiling* is meant to reflect the fact that all *function call*, *function return*, and *exception* events are monitored, and precise timings are made for the intervals between these events (during which time the user's code is executing). In contrast, *statistical profiling* (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required in order to do deterministic profiling. Python automatically provides a *hook* (optional callback) for each event. In addition, the interpreted

nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify “hot loops” that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.

## Limitations

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying “clock” is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the “error” will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it “takes a while” from when an event is dispatched until the profiler’s call to get the time actually gets the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock’s value was obtained (and then squirreled away), until the user’s code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it *can* accumulate and become very significant.

The problem is more important with `profile` than with the lower-overhead `cProfile`. For this reason, `profile` provides a means of calibrating itself for a given platform so that this error can

be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-). ) Do *not* be alarmed by negative numbers in the profile. They should *only* appear if you have calibrated your profiler, and the results are actually better than without calibration.

## Calibration

The profiler of the [profile](#) module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see [Limitations](#)).

```
import profile
pr = profile.Profile()
for i in range(5):
    print(pr.calibrate(10000))
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on a 1.8Ghz Intel Core i5 running macOS, and using Python's `time.process_time()` as the timer, the magical number is about  $4.04e-6$ .

The object of this exercise is to get a fairly consistent result. If your computer is *very* fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it:

```
import profile
```

```
# 1. Apply computed bias to all Profile instances created
profile.Profile.bias = your_computed_bias
```

```
# 2. Apply computed bias to a specific Profile instance.  
pr = profile.Profile()  
pr.bias = your_computed_bias
```

```
# 3. Specify computed bias in instance constructor.  
pr = profile.Profile(bias=your_computed_bias)
```

If you have a choice, you are better off choosing a smaller constant, and then your results will “less often” show up as negative in profile statistics.

## Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the **Profile** class constructor:

```
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call `your_time_func`. Depending on whether you are using **profile.Profile** or **cProfile.Profile**, `your_time_func`’s return value will be interpreted differently:

### **profile.Profile**

`your_time_func` should return a single number, or a list of numbers whose sum is the current time (like what **os.times()** returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.

Be warned that you should calibrate the profiler class for the timer function that you choose (see [Calibration](#)). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (**os.times()** is *pretty* bad, as it returns a tuple of floating point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer

call, along with the appropriate calibration constant.

### **cProfile.Profile**

`your_time_func` should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the **Profile** instance as follows:

```
pr = cProfile.Profile(your_integer_time_func, 0.001)
```

As the **cProfile.Profile** class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal **\_lsprof** module.

Python 3.3 adds several new functions in **time** that can be used to make precise measurements of process or wall-clock time. For example, see **time.perf\_counter()**.

# timeit — Measure execution time of small code snippets

**Source code:** [Lib/timeit.py](https://github.com/python/cpython/tree/3.12/Lib/timeit.py) [https://github.com/python/cpython/tree/3.12/Lib/timeit.py]

---

This module provides a simple way to time small bits of Python code. It has both a [Command-Line Interface](#) as well as a [callable](#) one. It avoids a number of common traps for measuring execution times. See also Tim Peters' introduction to the “Algorithms” chapter in the second edition of *Python Cookbook*, published by O'Reilly.

## Basic Examples

The following example shows how the [Command-Line Interface](#) can be used to compare three different expressions:

```
$ python -m timeit "'-'.join(str(n) for n in range(100))"
10000 loops, best of 5: 30.2 usec per loop
$ python -m timeit "'-'.join([str(n) for n in range(100)])"
10000 loops, best of 5: 27.5 usec per loop
$ python -m timeit "'-'.join(map(str, range(100)))"
10000 loops, best of 5: 23.2 usec per loop
```

This can be achieved from the [Python Interface](#) with:

```
>>> import timeit
>>> timeit.timeit("'-' .join(str(n) for n in range(100))")
0.3018611848820001
>>> timeit.timeit("'-' .join([str(n) for n in range(100)])")
0.2727368790656328
>>> timeit.timeit("'-' .join(map(str, range(100)))", number=100000)
0.23702679807320237
```

A callable can also be passed from the [Python Interface](#):

```
>>> timeit.timeit(lambda: "-".join(map(str, range(100))))  
0.19665591977536678
```

Note however that `timeit()` will automatically determine the number of repetitions only when the command-line interface is used. In the [Examples](#) section you can find more advanced examples.

## Python Interface

The module defines three convenience functions and a public class:

```
timeit.timeit(stmt='pass', setup='pass', timer=<default timer>,  
number=1000000, globals=None)
```

Create a [Timer](#) instance with the given statement, *setup* code and *timer* function and run its `timeit()` method with *number* executions. The optional *globals* argument specifies a namespace in which to execute the code.

*Changed in version 3.5:* The optional *globals* parameter was added.

```
timeit.repeat(stmt='pass', setup='pass', timer=<default timer>,  
repeat=5, number=1000000, globals=None)
```

Create a [Timer](#) instance with the given statement, *setup* code and *timer* function and run its `repeat()` method with the given *repeat* count and *number* executions. The optional *globals* argument specifies a namespace in which to execute the code.

*Changed in version 3.5:* The optional *globals* parameter was added.

*Changed in version 3.7:* Default value of *repeat* changed from 3 to 5.

```
timeit.default_timer()
```

The default timer, which is always `time.perf_counter()`, returns float seconds. An alternative, `time.perf_counter_ns`, returns integer nanoseconds.

*Changed in version 3.3:* `time.perf_counter()` is now the default timer.

```
class timeit.Timer(stmt='pass', setup='pass', timer=<timer
function>, globals=None)
```

Class for timing execution speed of small code snippets.

The constructor takes a statement to be timed, an additional statement used for setup, and a timer function. Both statements default to `'pass'`; the timer function is platform-dependent (see the module doc string). `stmt` and `setup` may also contain multiple statements separated by `;` or newlines, as long as they don't contain multi-line string literals. The statement will by default be executed within `timeit`'s namespace; this behavior can be controlled by passing a namespace to `globals`.

To measure the execution time of the first statement, use the `timeit()` method. The `repeat()` and `autorange()` methods are convenience methods to call `timeit()` multiple times.

The execution time of `setup` is excluded from the overall timed execution run.

The `stmt` and `setup` parameters can also take objects that are callable without arguments. This will embed calls to them in a timer function that will then be executed by `timeit()`. Note that the timing overhead is a little larger in this case because of the extra function calls.

*Changed in version 3.5:* The optional `globals` parameter was added.

```
timeit(number=1000000)
```

Time *number* executions of the main statement. This

executes the setup statement once, and then returns the time it takes to execute the main statement a number of times. The default timer returns seconds as a float. The argument is the number of times through the loop, defaulting to one million. The main statement, the setup statement and the timer function to be used are passed to the constructor.

### Note

By default, `timeit()` temporarily turns off [garbage collection](#) during the timing. The advantage of this approach is that it makes independent timings more comparable. The disadvantage is that GC may be an important component of the performance of the function being measured. If so, GC can be re-enabled as the first statement in the *setup* string. For example:

```
timeit.Timer('for i in range(10): oct(i)', 'gc')
```

`autorange(callback=None)`

Automatically determine how many times to call `timeit()`.

This is a convenience function that calls `timeit()` repeatedly so that the total time  $\geq 0.2$  second, returning the eventual (number of loops, time taken for that number of loops). It calls `timeit()` with increasing numbers from the sequence 1, 2, 5, 10, 20, 50, ... until the time taken is at least 0.2 seconds.

If *callback* is given and is not `None`, it will be called after each trial with two arguments:

```
callback(number, time_taken).
```

*New in version 3.6.*

`repeat(repeat=5, number=1000000)`

Call `timeit()` a few times.

This is a convenience function that calls the `timeit()` repeatedly, returning a list of results. The first argument specifies how many times to call `timeit()`. The second argument specifies the *number* argument for `timeit()`.

### Note

It's tempting to calculate mean and standard deviation from the result vector and report these. However, this is not very useful. In a typical case, the lowest value gives a lower bound for how fast your machine can run the given code snippet; higher values in the result vector are typically not caused by variability in Python's speed, but by other processes interfering with your timing accuracy. So the `min()` of the result is probably the only number you should be interested in. After that, you should look at the entire vector and apply common sense rather than statistics.

*Changed in version 3.7:* Default value of *repeat* changed from 3 to 5.

`print_exc(file=None)`

Helper to print a traceback from the timed code.

Typical use:

```
t = Timer(...)           # outside the try/except
try:
    t.timeit(...)         # or t.repeat(...)
except Exception:
    t.print_exc()
```

The advantage over the standard traceback is that source lines in the compiled template will be displayed. The optional *file* argument directs where the traceback

is sent; it defaults to `sys.stderr`.

## Command-Line Interface

When called as a program from the command line, the following form is used:

```
python -m timeit [-n N] [-r N] [-u U] [-s S] [-p] [-v] [
```

Where the following options are understood:

`-n N`, `--number=N`

how many times to execute ‘statement’

`-r N`, `--repeat=N`

how many times to repeat the timer (default 5)

`-s S`, `--setup=S`

statement to be executed once initially (default `pass`)

`-p`, `--process`

measure process time, not wallclock time, using `time.process_time()` instead of `time.perf_counter()`, which is the default

*New in version 3.3.*

`-u`, `--unit=U`

specify a time unit for timer output; can select `nsec`, `usec`, `msec`, or `sec`

*New in version 3.5.*

`-v`, `--verbose`

print raw timing results; repeat for more digits precision

`-h`, `--help`

print a short usage message and exit

A multi-line statement may be given by specifying each line as a separate statement argument; indented lines are possible by enclosing an argument in quotes and using leading spaces. Multiple **-s** options are treated similarly.

If **-n** is not given, a suitable number of loops is calculated by trying increasing numbers from the sequence 1, 2, 5, 10, 20, 50, ... until the total time is at least 0.2 seconds.

**default\_timer()** measurements can be affected by other programs running on the same machine, so the best thing to do when accurate timing is necessary is to repeat the timing a few times and use the best time. The **-r** option is good for this; the default of 5 repetitions is probably enough in most cases. You can use **time.process\_time()** to measure CPU time.

### Note

There is a certain baseline overhead associated with executing a pass statement. The code here doesn't try to hide it, but you should be aware of it. The baseline overhead can be measured by invoking the program without arguments, and it might differ between Python versions.

## Examples

It is possible to provide a setup statement that is executed only once at the beginning:

```
$ python -m timeit -s "text = 'sample string'; char = 'g'
5000000 loops, best of 5: 0.0877 usec per loop
$ python -m timeit -s "text = 'sample string'; char = 'g'
1000000 loops, best of 5: 0.342 usec per loop
```

In the output, there are three fields. The loop count, which tells you how many times the statement body was run per timing loop repetition. The repetition count ('best of 5') which tells you how many times the timing loop was repeated, and finally the time the statement body took on average within the best repetition of the

timing loop. That is, the time the fastest repetition took divided by the loop count.

```
>>> import timeit
>>> timeit.timeit('char in text', setup='text = "sample
0.41440500499993504
>>> timeit.timeit('text.find(char)', setup='text = "sample
1.7246671520006203
```

The same can be done using the [Timer](#) class and its methods:

```
>>> import timeit
>>> t = timeit.Timer('char in text', setup='text = "sample
>>> t.timeit()
0.3955516149999312
>>> t.repeat()
[0.40183617287970225, 0.37027556854118704, 0.38344867356
```

The following examples show how to time expressions that contain multiple lines. Here we compare the cost of using [hasattr\(\)](#) vs. [try/except](#) to test for missing and present object attributes:

```
$ python -m timeit "try:" " str.__bool__" "except AttributeError:
20000 loops, best of 5: 15.7 usec per loop
$ python -m timeit "if hasattr(str, '__bool__'): pass"
50000 loops, best of 5: 4.26 usec per loop
```

```
$ python -m timeit "try:" " int.__bool__" "except AttributeError:
200000 loops, best of 5: 1.43 usec per loop
$ python -m timeit "if hasattr(int, '__bool__'): pass"
100000 loops, best of 5: 2.23 usec per loop
```

```
>>> import timeit
>>> # attribute is missing
>>> s = ""
... try:
...     str.__bool__
... except AttributeError:
...     pass
... ""
```

```

>>> timeit.timeit(stmt=s, number=100000)
0.9138244460009446
>>> s = "if hasattr(str, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.5829014980008651
>>>
>>> # attribute is present
>>> s = """\
... try:
...     int.__bool__
... except AttributeError:
...     pass
... """
>>> timeit.timeit(stmt=s, number=100000)
0.04215312199994514
>>> s = "if hasattr(int, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.08588060699912603

```

To give the `timeit` module access to functions you define, you can pass a *setup* parameter which contains an import statement:

```

def test():
    """Stupid test function"""
    L = [i for i in range(100)]

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()", setup="from __main__ i

```

Another option is to pass `globals()` to the *globals* parameter, which will cause the code to be executed within your current global namespace. This can be more convenient than individually specifying imports:

```

def f(x):
    return x**2
def g(x):
    return x**4

```

```
def h(x):  
    return x**8
```

```
import timeit
```

```
print(timeit.timeit('[func(42) for func in (f,g,h)]', gl
```

# **trace** — Trace or track Python statement execution

**Source code:** [Lib/trace.py](https://github.com/python/cpython/tree/3.12/Lib/trace.py) [https://github.com/python/cpython/tree/3.12/Lib/trace.py]

---

The **trace** module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.

## See also

**Coverage.py** [https://coverage.readthedocs.io/]

A popular third-party coverage tool that provides HTML output along with advanced features such as branch coverage.

## Command-Line Usage

The **trace** module can be invoked from the command line. It can be as simple as

```
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

`--help`

Display usage and exit.

`--version`

Display the version of the module and exit.

*New in version 3.8:* Added `--module` option that allows to run an executable module.

## Main options

At least one of the following options must be specified when invoking `trace`. The `--listfuncs` option is mutually exclusive with the `--trace` and `--count` options. When `--listfuncs` is provided, neither `--count` nor `--trace` are accepted, and vice versa.

`-c, --count`

Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also `--coverdir`, `--file` and `--no-report` below.

`-t, --trace`

Display lines as they are executed.

`-l, --listfuncs`

Display the functions executed by running the program.

`-r, --report`

Produce an annotated list from an earlier program run that used the `--count` and `--file` option. This does not execute any code.

`-T, --trackcalls`

Display the calling relationships exposed by running the program.

## Modifiers

`-f, --file= <file>`

Name of a file to accumulate counts over several tracing runs.

Should be used with the `--count` option.

`-C, --coverdir = <dir>`

Directory where the report files go. The coverage report for `package.module` is written to file `dir/package/module.cover`.

`-m, --missing`

When generating annotated listings, mark lines which were not executed with `>>>>>>`.

`-s, --summary`

When using `--count` or `--report`, write a brief summary to stdout for each file processed.

`-R, --no-report`

Do not generate annotated listings. This is useful if you intend to make several runs with `--count`, and then produce a single set of annotated listings at the end.

`-g, --timing`

Prefix each line with the time since the program started. Only used while tracing.

## Filters

These options may be repeated multiple times.

`--ignore-module = <mod>`

Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.

`--ignore-dir = <dir>`

Ignore all modules and packages in the named directory and subdirectories. The argument can be a list of directories separated by `os.pathsep`.

# Programmatic Interface

```
class trace.Trace(count=1, trace=1, countfuncs=0, countcallers=0,
ignoremods=(), ignoredirs=(), infile=None, outfile=None,
timing=False)
```

Create an object to trace execution of a single statement or expression. All parameters are optional. *count* enables counting of line numbers. *trace* enables line execution tracing. *countfuncs* enables listing of the functions called during the run. *countcallers* enables call relationship tracking. *ignoremods* is a list of modules or packages to ignore. *ignoredirs* is a list of directories whose modules or packages should be ignored. *infile* is the name of the file from which to read stored count information. *outfile* is the name of the file in which to write updated count information. *timing* enables a timestamp relative to when tracing was started to be displayed.

`run(cmd)`

Execute the command and gather statistics from the execution with the current tracing parameters. *cmd* must be a string or code object, suitable for passing into `exec()`.

`runtx(cmd, globals=None, locals=None)`

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, *globals* and *locals* default to empty dictionaries.

`runfunc(func, /, *args, **kwargs)`

Call *func* with the given arguments under control of the `Trace` object with the current tracing parameters.

`results()`

Return a `CoverageResults` object that contains the cumulative results of all previous calls to `run`, `runtx` and `runfunc` for the given `Trace` instance.

Does not reset the accumulated trace results.

*class* `trace.CoverageResults`

A container for coverage results, created by `Trace.results()`. Should not be created directly by the user.

`update(other)`

Merge in data from another `CoverageResults` object.

`write_results(show_missing=True, summary=False, coverdir=None)`

Write coverage results. Set *show\_missing* to show lines that had no hits. Set *summary* to include in the output the coverage summary per module. *coverdir* specifies the directory into which the coverage result files will be output. If `None`, the results for each source file are placed in its directory.

A simple example demonstrating the use of the programmatic interface:

```
import sys
import trace
```

```
# create a Trace object, telling it what to ignore, and
# do tracing or line-counting or both.
```

```
tracer = trace.Trace(
    ignoredirs=[sys.prefix, sys.exec_prefix],
    trace=0,
    count=1)
```

```
# run the new command using the given tracer
tracer.run('main()')
```

```
# make a report, placing output in the current directory
r = tracer.results()
```

```
r.write_results(show_missing=True, coverdir=".")
```

# tracemalloc — Trace memory allocations

*New in version 3.4.*

**Source code:** [Lib/tracemalloc.py](https://github.com/python/cpython/tree/3.12/Lib/tracemalloc.py) [https://github.com/python/cpython/tree/3.12/Lib/tracemalloc.py]

---

The tracemalloc module is a debug tool to trace memory blocks allocated by Python. It provides the following information:

- Traceback where an object was allocated
- Statistics on allocated memory blocks per filename and per line number: total size, number and average size of allocated memory blocks
- Compute the differences between two snapshots to detect memory leaks

To trace most memory blocks allocated by Python, the module should be started as early as possible by setting the `PYTHONTRACEMALLOC` environment variable to `1`, or by using `-X tracemalloc` command line option. The `tracemalloc.start()` function can be called at runtime to start tracing Python memory allocations.

By default, a trace of an allocated memory block only stores the most recent frame (1 frame). To store 25 frames at startup: set the `PYTHONTRACEMALLOC` environment variable to `25`, or use the `-X tracemalloc=25` command line option.

## Examples

### Display the top 10

Display the 10 files allocating the most memory:

```
import tracemalloc

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('lineno')

print("[ Top 10 ]")
for stat in top_stats[:10]:
    print(stat)
```

Example of output of the Python test suite:

```
[ Top 10 ]
<frozen importlib._bootstrap>:716: size=4855 KiB, count=3
<frozen importlib._bootstrap>:284: size=521 KiB, count=3
/usr/lib/python3.4/collections/__init__.py:368: size=244
/usr/lib/python3.4/unittest/case.py:381: size=185 KiB, count=3
/usr/lib/python3.4/unittest/case.py:402: size=154 KiB, count=3
/usr/lib/python3.4/abc.py:133: size=88.7 KiB, count=347
<frozen importlib._bootstrap>:1446: size=70.4 KiB, count=3
<frozen importlib._bootstrap>:1454: size=52.0 KiB, count=3
<string>:5: size=49.7 KiB, count=148, average=344 B
/usr/lib/python3.4/sysconfig.py:411: size=48.0 KiB, count=3
```

We can see that Python loaded 4855 KiB data (bytecode and constants) from modules and that the `collections` module allocated 244 KiB to build `namedtuple` types.

See `Snapshot.statistics()` for more options.

## Compute differences

Take two snapshots and display the differences:

```
import tracemalloc
```

```

tracemalloc.start()
# ... start your application ...

snapshot1 = tracemalloc.take_snapshot()
# ... call the function leaking memory ...
snapshot2 = tracemalloc.take_snapshot()

top_stats = snapshot2.compare_to(snapshot1, 'lineno')

print("[ Top 10 differences ]")
for stat in top_stats[:10]:
    print(stat)

```

Example of output before/after running some tests of the Python test suite:

```

[ Top 10 differences ]
<frozen importlib._bootstrap>:716: size=8173 KiB (+4428
/usr/lib/python3.4/linecache.py:127: size=940 KiB (+940
/usr/lib/python3.4/unittest/case.py:571: size=298 KiB (+
<frozen importlib._bootstrap>:284: size=1005 KiB (+166 K
/usr/lib/python3.4/mimetypes.py:217: size=112 KiB (+112
/usr/lib/python3.4/http/server.py:848: size=96.0 KiB (+9
/usr/lib/python3.4/inspect.py:1465: size=83.5 KiB (+83.5
/usr/lib/python3.4/unittest/mock.py:491: size=77.7 KiB (
/usr/lib/python3.4/urllib/parse.py:476: size=71.8 KiB (+
/usr/lib/python3.4/contextlib.py:38: size=67.2 KiB (+67.

```

We can see that Python has loaded 8173 KiB of module data (bytecode and constants), and that this is 4428 KiB more than had been loaded before the tests, when the previous snapshot was taken. Similarly, the `linecache` module has cached 940 KiB of Python source code to format tracebacks, all of it since the previous snapshot.

If the system has little free memory, snapshots can be written on disk using the `Snapshot.dump()` method to analyze the snapshot offline. Then use the `Snapshot.load()` method reload the snapshot.

## Get the traceback of a memory block

Code to display the traceback of the biggest memory block:

```
import tracemalloc

# Store 25 frames
tracemalloc.start(25)

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('traceback')

# pick the biggest memory block
stat = top_stats[0]
print("%s memory blocks: %.1f KiB" % (stat.count, stat.size))
for line in stat.traceback.format():
    print(line)
```

Example of output of the Python test suite (traceback limited to 25 frames):

```
903 memory blocks: 870.1 KiB
File "<frozen importlib._bootstrap>", line 716
File "<frozen importlib._bootstrap>", line 1036
File "<frozen importlib._bootstrap>", line 934
File "<frozen importlib._bootstrap>", line 1068
File "<frozen importlib._bootstrap>", line 619
File "<frozen importlib._bootstrap>", line 1581
File "<frozen importlib._bootstrap>", line 1614
File "/usr/lib/python3.4/doctest.py", line 101
    import pdb
File "<frozen importlib._bootstrap>", line 284
File "<frozen importlib._bootstrap>", line 938
File "<frozen importlib._bootstrap>", line 1068
File "<frozen importlib._bootstrap>", line 619
File "<frozen importlib._bootstrap>", line 1581
File "<frozen importlib._bootstrap>", line 1614
```

```

File "/usr/lib/python3.4/test/support/__init__.py", li
    import doctest
File "/usr/lib/python3.4/test/test_pickletools.py", li
    support.run_doctest(pickletools)
File "/usr/lib/python3.4/test/regrtest.py", line 1276
    test_runner()
File "/usr/lib/python3.4/test/regrtest.py", line 976
    display_failure=not verbose)
File "/usr/lib/python3.4/test/regrtest.py", line 761
    match_tests=ns.match_tests)
File "/usr/lib/python3.4/test/regrtest.py", line 1563
    main()
File "/usr/lib/python3.4/test/__main__.py", line 3
    regrtest.main_in_temp_cwd()
File "/usr/lib/python3.4/runpy.py", line 73
    exec(code, run_globals)
File "/usr/lib/python3.4/runpy.py", line 160
    "__main__", fname, loader, pkg_name)

```

We can see that the most memory was allocated in the `importlib` module to load data (bytecode and constants) from modules: 870.1 KiB. The traceback is where the `importlib` loaded data most recently: on the `import pdb` line of the `doctest` module. The traceback may change if a new module is loaded.

## Pretty top

Code to display the 10 lines allocating the most memory with a pretty output, ignoring `<frozen importlib._bootstrap>` and `<unknown>` files:

```

import linecache
import os
import tracemalloc

def display_top(snapshot, key_type='lineno', limit=10):
    snapshot = snapshot.filter_traces((
        tracemalloc.Filter(False, "<frozen importlib._bo
        tracemalloc.Filter(False, "<unknown>"),

```

```

))
top_stats = snapshot.statistics(key_type)

print("Top %s lines" % limit)
for index, stat in enumerate(top_stats[:limit], 1):
    frame = stat.traceback[0]
    print("#%s: %s:%s: %.1f KiB"
          % (index, frame.filename, frame.lineno, stat.size))
    line = linecache.getline(frame.filename, frame.lineno, frame.f_globals, None)
    if line:
        print('    %s' % line)

other = top_stats[limit:]
if other:
    size = sum(stat.size for stat in other)
    print("%s other: %.1f KiB" % (len(other), size))
total = sum(stat.size for stat in top_stats)
print("Total allocated size: %.1f KiB" % (total / 1024))

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
display_top(snapshot)

```

### Example of output of the Python test suite:

```

Top 10 lines
#1: Lib/base64.py:414: 419.8 KiB
    _b85chars2 = [(a + b) for a in _b85chars for b in _b85chars]
#2: Lib/base64.py:306: 419.8 KiB
    _a85chars2 = [(a + b) for a in _a85chars for b in _a85chars]
#3: collections/__init__.py:368: 293.6 KiB
    exec(class_definition, namespace)
#4: Lib/abc.py:133: 115.2 KiB
    cls = super().__new__(mcls, name, bases, namespace)
#5: unittest/case.py:574: 103.1 KiB
    testMethod()

```

```
#6: Lib/linecache.py:127: 95.4 KiB
    lines = fp.readlines()
#7: urllib/parse.py:476: 71.8 KiB
    for a in _hexdig for b in _hexdig}
#8: <string>:5: 62.0 KiB
#9: Lib/_weakrefset.py:37: 60.0 KiB
    self.data = set()
#10: Lib/base64.py:142: 59.8 KiB
    _b32tab2 = [a + b for a in _b32tab for b in _b32tab]
6220 other: 3602.8 KiB
Total allocated size: 5303.1 KiB
```

See [`Snapshot.statistics\(\)`](#) for more options.

## Record the current and peak size of all traced memory blocks

The following code computes two sums like  $0 + 1 + 2 + \dots$  inefficiently, by creating a list of those numbers. This list consumes a lot of memory temporarily. We can use [`get\_traced\_memory\(\)`](#) and [`reset\_peak\(\)`](#) to observe the small memory usage after the sum is computed as well as the peak memory usage during the computations:

```
import tracemalloc

tracemalloc.start()

# Example code: compute a sum with a large temporary list
large_sum = sum(list(range(100000)))

first_size, first_peak = tracemalloc.get_traced_memory()

tracemalloc.reset_peak()

# Example code: compute a sum with a small temporary list
small_sum = sum(list(range(1000)))

second_size, second_peak = tracemalloc.get_traced_memory()
```

```
print(f"{first_size=}, {first_peak=}")
print(f"{second_size=}, {second_peak=}")
```

Output:

```
first_size=664, first_peak=3592984
second_size=804, second_peak=29704
```

Using `reset_peak()` ensured we could accurately record the peak during the computation of `small_sum`, even though it is much smaller than the overall peak size of memory blocks since the `start()` call. Without the call to `reset_peak()`, `second_peak` would still be the peak from the computation `large_sum` (that is, equal to `first_peak`). In this case, both peaks are much higher than the final memory usage, and which suggests we could optimise (by removing the unnecessary call to `list`, and writing `sum(range(...))`).

## API

### Functions

`tracemalloc.clear_traces()`

Clear traces of memory blocks allocated by Python.

See also `stop()`.

`tracemalloc.get_object_traceback(obj)`

Get the traceback where the Python object *obj* was allocated. Return a `Traceback` instance, or `None` if the `tracemalloc` module is not tracing memory allocations or did not trace the allocation of the object.

See also `gc.get_referrers()` and `sys.getsizeof()` functions.

`tracemalloc.get_traceback_limit()`

Get the maximum number of frames stored in the traceback

of a trace.

The `tracemalloc` module must be tracing memory allocations to get the limit, otherwise an exception is raised.

The limit is set by the `start()` function.

`tracemalloc.get_traced_memory()`

Get the current size and peak size of memory blocks traced by the `tracemalloc` module as a tuple: (current: int, peak: int).

`tracemalloc.reset_peak()`

Set the peak size of memory blocks traced by the `tracemalloc` module to the current size.

Do nothing if the `tracemalloc` module is not tracing memory allocations.

This function only modifies the recorded peak size, and does not modify or clear any traces, unlike `clear_traces()`. Snapshots taken with `take_snapshot()` before a call to `reset_peak()` can be meaningfully compared to snapshots taken after the call.

See also `get_traced_memory()`.

*New in version 3.9.*

`tracemalloc.get_tracemalloc_memory()`

Get the memory usage in bytes of the `tracemalloc` module used to store traces of memory blocks. Return an `int`.

`tracemalloc.is_tracing()`

True if the `tracemalloc` module is tracing Python memory allocations, False otherwise.

See also `start()` and `stop()` functions.

`tracemalloc.start(nframe: int = 1)`

Start tracing Python memory allocations: install hooks on Python memory allocators. Collected tracebacks of traces will be limited to *nframe* frames. By default, a trace of a memory block only stores the most recent frame: the limit is 1. *nframe* must be greater or equal to 1.

You can still read the original number of total frames that composed the traceback by looking at the `Traceback.total_nframe` attribute.

Storing more than 1 frame is only useful to compute statistics grouped by 'traceback' or to compute cumulative statistics: see the `Snapshot.compare_to()` and `Snapshot.statistics()` methods.

Storing more frames increases the memory and CPU overhead of the `tracemalloc` module. Use the `get_tracemalloc_memory()` function to measure how much memory is used by the `tracemalloc` module.

The `PYTHONTRACEMALLOC` environment variable (`PYTHONTRACEMALLOC=NFRAME`) and the `-X tracemalloc=NFRAME` command line option can be used to start tracing at startup.

See also `stop()`, `is_tracing()` and `get_traceback_limit()` functions.

`tracemalloc.stop()`

Stop tracing Python memory allocations: uninstall hooks on Python memory allocators. Also clears all previously collected traces of memory blocks allocated by Python.

Call `take_snapshot()` function to take a snapshot of traces before clearing them.

See also `start()`, `is_tracing()` and `clear_traces()` functions.

`tracemalloc.take_snapshot()`

Take a snapshot of traces of memory blocks allocated by Python. Return a new `Snapshot` instance.

The snapshot does not include memory blocks allocated before the `tracemalloc` module started to trace memory allocations.

Tracebacks of traces are limited to `get_traceback_limit()` frames. Use the `nframe` parameter of the `start()` function to store more frames.

The `tracemalloc` module must be tracing memory allocations to take a snapshot, see the `start()` function.

See also the `get_object_traceback()` function.

## DomainFilter

`class tracemalloc.DomainFilter(inclusive: bool, domain: int)`

Filter traces of memory blocks by their address space (domain).

*New in version 3.6.*

**inclusive**

If *inclusive* is `True` (include), match memory blocks allocated in the address space `domain`.

If *inclusive* is `False` (exclude), match memory blocks not allocated in the address space `domain`.

**domain**

Address space of a memory block (`int`). Read-only property.

## Filter

`class tracemalloc.Filter(inclusive: bool, filename_pattern: str, lineno: int)`

= None, all\_frames: bool = False, domain: int = None)

Filter on traces of memory blocks.

See the `fnmatch.fnmatch()` function for the syntax of *filename\_pattern*. The `'.pyc'` file extension is replaced with `'.py'`.

Examples:

- `Filter(True, subprocess.__file__)` only includes traces of the `subprocess` module
- `Filter(False, tracemalloc.__file__)` excludes traces of the `tracemalloc` module
- `Filter(False, "<unknown>")` excludes empty tracebacks

*Changed in version 3.5:* The `'.pyo'` file extension is no longer replaced with `'.py'`.

*Changed in version 3.6:* Added the `domain` attribute.

**domain**

Address space of a memory block (int or None).

`tracemalloc` uses the domain `0` to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

**inclusive**

If *inclusive* is `True` (include), only match memory blocks allocated in a file with a name matching `filename_pattern` at line number `lineno`.

If *inclusive* is `False` (exclude), ignore memory blocks allocated in a file with a name matching `filename_pattern` at line number `lineno`.

**lineno**

Line number (int) of the filter. If *lineno* is `None`, the filter matches any line number.

`filename_pattern`

Filename pattern of the filter (`str`). Read-only property.

`all_frames`

If `all_frames` is `True`, all frames of the traceback are checked. If `all_frames` is `False`, only the most recent frame is checked.

This attribute has no effect if the traceback limit is `1`. See the `get_traceback_limit()` function and `Snapshot.traceback_limit` attribute.

## Frame

`class tracemalloc.Frame`

Frame of a traceback.

The `Traceback` class is a sequence of `Frame` instances.

`filename`

Filename (`str`).

`lineno`

Line number (`int`).

## Snapshot

`class tracemalloc.Snapshot`

Snapshot of traces of memory blocks allocated by Python.

The `take_snapshot()` function creates a snapshot instance.

`compare_to(old_snapshot: Snapshot, key_type: str, cumulative: bool = False)`

Compute the differences with an old snapshot. Get statistics as a sorted list of `StatisticDiff` instances

grouped by *key\_type*.

See the `Snapshot.statistics()` method for *key\_type* and *cumulative* parameters.

The result is sorted from the biggest to the smallest by: absolute value of `StatisticDiff.size_diff`, `StatisticDiff.size`, absolute value of `StatisticDiff.count_diff`, `Statistic.count` and then by `StatisticDiff.traceback`.

`dump(filename)`

Write the snapshot into a file.

Use `load()` to reload the snapshot.

`filter_traces(filters)`

Create a new `Snapshot` instance with a filtered `traces` sequence, *filters* is a list of `DomainFilter` and `Filter` instances. If *filters* is an empty list, return a new `Snapshot` instance with a copy of the traces.

All inclusive filters are applied at once, a trace is ignored if no inclusive filters match it. A trace is ignored if at least one exclusive filter matches it.

*Changed in version 3.6:* `DomainFilter` instances are now also accepted in *filters*.

`classmethod load(filename)`

Load a snapshot from a file.

See also `dump()`.

`statistics(key_type: str, cumulative: bool = False)`

Get statistics as a sorted list of `Statistic` instances grouped by *key\_type*:

**Key type**

---

<code>filename</code>	<code>'filename'</code>
<code>lineno</code>	<code>filename</code> and line number
<code>traceback</code>	<code>traceback</code>

If *cumulative* is `True`, cumulate size and count of memory blocks of all frames of the traceback of a trace, not only the most recent frame. The cumulative mode can only be used with *key\_type* equals to `'filename'` and `'lineno'`.

The result is sorted from the biggest to the smallest by: `Statistic.size`, `Statistic.count` and then by `Statistic.traceback`.

`traceback_limit`

Maximum number of frames stored in the traceback of `traces`: result of the `get_traceback_limit()` when the snapshot was taken.

`traces`

Traces of all memory blocks allocated by Python: sequence of `Trace` instances.

The sequence has an undefined order. Use the `Snapshot.statistics()` method to get a sorted list of statistics.

## Statistic

`class tracemalloc.Statistic`

Statistic on memory allocations.

`Snapshot.statistics()` returns a list of `Statistic` instances.

See also the `StatisticDiff` class.

`count`

Number of memory blocks (`int`).

size

Total size of memory blocks in bytes (`int`).

traceback

Traceback where the memory block was allocated, `Traceback` instance.

## StatisticDiff

*class* tracemalloc.StatisticDiff

Statistic difference on memory allocations between an old and a new `Snapshot` instance.

`Snapshot.compare_to()` returns a list of `StatisticDiff` instances. See also the `Statistic` class.

count

Number of memory blocks in the new snapshot (`int`): 0 if the memory blocks have been released in the new snapshot.

count\_diff

Difference of number of memory blocks between the old and the new snapshots (`int`): 0 if the memory blocks have been allocated in the new snapshot.

size

Total size of memory blocks in bytes in the new snapshot (`int`): 0 if the memory blocks have been released in the new snapshot.

size\_diff

Difference of total size of memory blocks in bytes between the old and the new snapshots (`int`): 0 if the memory blocks have been allocated in the new snapshot.

traceback

Traceback where the memory blocks were allocated,  
**Traceback** instance.

## Trace

*class* tracemalloc.Trace

Trace of a memory block.

The **Snapshot.traces** attribute is a sequence of **Trace** instances.

*Changed in version 3.6:* Added the **domain** attribute.

domain

Address space of a memory block (**int**). Read-only property.

tracemalloc uses the domain `0` to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

size

Size of the memory block in bytes (**int**).

traceback

Traceback where the memory block was allocated,  
**Traceback** instance.

## Traceback

*class* tracemalloc.Traceback

Sequence of **Frame** instances sorted from the oldest frame to the most recent frame.

A traceback contains at least `1` frame. If the `tracemalloc` module failed to get a frame, the filename `"<unknown>"` at line number `0` is used.

When a snapshot is taken, tracebacks of traces are limited to

`get_traceback_limit()` frames. See the `take_snapshot()` function. The original number of frames of the traceback is stored in the `Traceback.total_nframe` attribute. That allows to know if a traceback has been truncated by the traceback limit.

The `Trace.traceback` attribute is an instance of `Traceback` instance.

*Changed in version 3.7:* Frames are now sorted from the oldest to the most recent, instead of most recent to oldest.

`total_nframe`

Total number of frames that composed the traceback before truncation. This attribute can be set to `None` if the information is not available.

*Changed in version 3.9:* The `Traceback.total_nframe` attribute was added.

`format(limit=None, most_recent_first=False)`

Format the traceback as a list of lines. Use the `linecache` module to retrieve lines from the source code. If `limit` is set, format the `limit` most recent frames if `limit` is positive. Otherwise, format the `abs(limit)` oldest frames. If `most_recent_first` is `True`, the order of the formatted frames is reversed, returning the most recent frame first instead of last.

Similar to the `traceback.format_tb()` function, except that `format()` does not include newlines.

Example:

```
print("Traceback (most recent call first):")
for line in traceback:
    print(line)
```

Output:

```
Traceback (most recent call first):  
  File "test.py", line 9  
    obj = Object()  
  File "test.py", line 12  
    tb = tracemalloc.get_object_traceback(f())
```

# Software Packaging and Distribution

These libraries help you with publishing and installing Python software. While these modules are designed to work in conjunction with the [Python Package Index](https://pypi.org) [https://pypi.org], they can also be used with a local index server, or without any index server at all.

# ensurepip — Bootstrapping the pip installer

*New in version 3.4.*

**Source code:** [Lib/ensurepip](https://github.com/python/cpython/tree/3.12/Lib/ensurepip) [https://github.com/python/cpython/tree/3.12/Lib/ensurepip]

---

The **ensurepip** package provides support for bootstrapping the pip installer into an existing Python installation or virtual environment. This bootstrapping approach reflects the fact that pip is an independent project with its own release cycle, and the latest available stable version is bundled with maintenance and feature releases of the CPython reference interpreter.

In most cases, end users of Python shouldn't need to invoke this module directly (as pip should be bootstrapped by default), but it may be needed if installing pip was skipped when installing Python (or when creating a virtual environment) or after explicitly uninstalling pip.

## Note

This module *does not* access the internet. All of the components needed to bootstrap pip are included as internal parts of the package.

## See also

### Installing Python Modules

The end user guide for installing Python packages

**PEP 453** [https://peps.python.org/pep-0453/]: **Explicit bootstrapping of pip in Python installations**

The original rationale and specification for this module.

[Availability](#): not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

## Command line interface

The command line interface is invoked using the interpreter's `-m` switch.

The simplest possible invocation is:

```
python -m ensurepip
```

This invocation will install `pip` if it is not already installed, but otherwise does nothing. To ensure the installed version of `pip` is at least as recent as the one available in `ensurepip`, pass the `--upgrade` option:

```
python -m ensurepip --upgrade
```

By default, `pip` is installed into the current virtual environment (if one is active) or into the system site packages (if there is no active virtual environment). The installation location can be controlled through two additional command line options:

- `--root dir`: Installs `pip` relative to the given root directory rather than the root of the currently active virtual environment (if any) or the default root for the current Python installation.
- `--user`: Installs `pip` into the user site packages directory rather than globally for the current Python installation (this option is not permitted inside an active virtual environment).

By default, the scripts `pipX` and `pipX.Y` will be installed (where `X.Y` stands for the version of Python used to invoke `ensurepip`). The scripts installed can be controlled through two additional

command line options:

- `--altinstall`: if an alternate installation is requested, the `pipX` script will *not* be installed.
- `--default-pip`: if a “default pip” installation is requested, the `pip` script will be installed in addition to the two regular scripts.

Providing both of the script selection options will trigger an exception.

## Module API

**ensurepip** exposes two functions for programmatic use:

`ensurepip.version()`

Returns a string specifying the available version of pip that will be installed when bootstrapping an environment.

`ensurepip.bootstrap(root=None, upgrade=False, user=False, altinstall=False, default_pip=False, verbosity=0)`

Bootstraps `pip` into the current or designated environment.

*root* specifies an alternative root directory to install relative to. If *root* is `None`, then installation uses the default install location for the current environment.

*upgrade* indicates whether or not to upgrade an existing installation of an earlier version of `pip` to the available version.

*user* indicates whether to use the user scheme rather than installing globally.

By default, the scripts `pipX` and `pipX.Y` will be installed (where `X.Y` stands for the current version of Python).

If *altinstall* is set, then `pipX` will *not* be installed.

If *default\_pip* is set, then `pip` will be installed in addition to

the two regular scripts.

Setting both *altinstall* and *default\_pip* will trigger **ValueError**.

*verbosity* controls the level of output to **sys.stdout** from the bootstrapping operation.

Raises an **auditing event** `ensurepip.bootstrap` with argument `root`.

### **Note**

The bootstrapping process has side effects on both `sys.path` and `os.environ`. Invoking the command line interface in a subprocess instead allows these side effects to be avoided.

### **Note**

The bootstrapping process may install additional modules required by `pip`, but other software should not assume those dependencies will always be present by default (as the dependencies may be removed in a future version of `pip`).

# venv — Creation of virtual environments

*New in version 3.3.*

**Source code:** [Lib/venv/](https://github.com/python/cpython/tree/3.12/Lib/venv/) [https://github.com/python/cpython/tree/3.12/Lib/venv/]

---

The **venv** module supports creating lightweight “virtual environments”, each with their own independent set of Python packages installed in their **site** directories. A virtual environment is created on top of an existing Python installation, known as the virtual environment’s “base” Python, and may optionally be isolated from the packages in the base environment, so only those explicitly installed in the virtual environment are available.

When used from within a virtual environment, common installation tools such as **pip** [https://pypi.org/project/pip/] will install Python packages into a virtual environment without needing to be told to do so explicitly.

A virtual environment is (amongst other things):

- Used to contain a specific Python interpreter and software libraries and binaries which are needed to support a project (library or application). These are by default isolated from software in other virtual environments and Python interpreters and libraries installed in the operating system.
- Contained in a directory, conventionally either named `venv` or `.venv` in the project directory, or under a container directory for lots of virtual environments, such as `~/virtualenvs`.
- Not checked into source control systems such as Git.
- Considered as disposable – it should be simple to delete and recreate it from scratch. You don’t place any project code in

the environment

- Not considered as movable or copyable – you just recreate the same environment in the target location.

See [PEP 405](https://peps.python.org/pep-0405/) [https://peps.python.org/pep-0405/] for more background on Python virtual environments.

## See also

[Python Packaging User Guide: Creating and using virtual environments](https://packaging.python.org/guides/installing-using-pip-and-virtual-environments/#creating-a-virtual-environment) [https://packaging.python.org/guides/installing-using-pip-and-virtual-environments/#creating-a-virtual-environment]

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

# Creating virtual environments

Creation of [virtual environments](#) is done by executing the command `venv`:

```
python -m venv /path/to/new/virtual/environment
```

Running this command creates the target directory (creating any parent directories that don't exist already) and places a `pyvenv.cfg` file in it with a `home` key pointing to the Python installation from which the command was run (a common name for the target directory is `.venv`). It also creates a `bin` (or `Scripts` on Windows) subdirectory containing a copy/symlink of the Python binary/binaries (as appropriate for the platform or arguments used at environment creation time). It also creates an (initially empty) `lib/pythonX.Y/site-packages` subdirectory (on Windows, this is `Lib\site-packages`). If an existing directory is specified, it will be re-used.

*Deprecated since version 3.6:* `pyvenv` was the recommended tool for creating virtual environments for Python 3.3 and 3.4, and is

deprecated in Python 3.6.

*Changed in version 3.5:* The use of `venv` is now recommended for creating virtual environments.

On Windows, invoke the `venv` command as follows:

```
c:\>Python35\python -m venv c:\path\to\myenv
```

Alternatively, if you configured the `PATH` and `PATHEXT` variables for your [Python installation](#):

```
c:\>python -m venv c:\path\to\myenv
```

The command, if run with `-h`, will show the available options:

```
usage: venv [-h] [--system-site-packages] [--symlinks |
            [--upgrade] [--without-pip] [--prompt PROMPT]
            ENV_DIR [ENV_DIR ...]
```

Creates virtual Python environments in one or more target

positional arguments:

<code>ENV_DIR</code>	A directory to create the environment in
----------------------	------------------------------------------

optional arguments:

<code>-h, --help</code>	show this help message and exit
<code>--system-site-packages</code>	Give the virtual environment access to the system site-packages dir.
<code>--symlinks</code>	Try to use symlinks rather than copies; only available on platforms where they are not the default for the platform.
<code>--copies</code>	Try to use copies rather than symlinks; only available on platforms where symlinks are the default for the platform.
<code>--clear</code>	Delete the contents of the environment directory if it already exists, before environment creation.
<code>--upgrade</code>	Upgrade the environment directory to the latest version of Python, assuming Python has been installed.
<code>--without-pip</code>	Skips installing or upgrading pip; you have to pip install it into the environment (pip is bootstrapped by default).

<code>--prompt PROMPT</code>	Provides an alternative prompt p environment.
<code>--upgrade-deps</code>	Upgrade core dependencies (pip) latest version in PyPI

Once an environment has been created, you may wish to add  
sourcing an activate script in its bin directory.

*Changed in version 3.12:* `setuptools` is no longer a core `venv`  
dependency.

*Changed in version 3.9:* Add `--upgrade-deps` option to upgrade  
`pip` + `setuptools` to the latest on PyPI

*Changed in version 3.4:* Installs `pip` by default, added the `--`  
`without-pip` and `--copies` options

*Changed in version 3.4:* In earlier versions, if the target directory  
already existed, an error was raised, unless the `--clear` or `--`  
`upgrade` option was provided.

## Note

While symlinks are supported on Windows, they are not  
recommended. Of particular note is that double-clicking  
`python.exe` in File Explorer will resolve the symlink eagerly  
and ignore the virtual environment.

## Note

On Microsoft Windows, it may be required to enable the  
`Activate.ps1` script by setting the execution policy for the  
user. You can do this by issuing the following PowerShell  
command:

```
PS C:> Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -  
Scope CurrentUser
```

See [About Execution Policies](https://go.microsoft.com/fwlink/?LinkID=135170) [https://go.microsoft.com/fwlink/?  
LinkID=135170] for more information.

The created `pyvenv.cfg` file also includes the `include-system-site-packages` key, set to `true` if `venv` is run with the `--system-site-packages` option, `false` otherwise.

Unless the `--without-pip` option is given, **ensurepip** will be invoked to bootstrap `pip` into the virtual environment.

Multiple paths can be given to `venv`, in which case an identical virtual environment will be created, according to the given options, at each provided path.

## How venvs work

When a Python interpreter is running from a virtual environment, **sys.prefix** and **sys.exec\_prefix** point to the directories of the virtual environment, whereas **sys.base\_prefix** and **sys.base\_exec\_prefix** point to those of the base Python used to create the environment. It is sufficient to check `sys.prefix != sys.base_prefix` to determine if the current interpreter is running from a virtual environment.

A virtual environment may be “activated” using a script in its binary directory (`bin` on POSIX; `Scripts` on Windows). This will prepend that directory to your **PATH**, so that running **python** will invoke the environment’s Python interpreter and you can run installed scripts without having to use their full path. The invocation of the activation script is platform-specific (`<venv>` must be replaced by the path to the directory containing the virtual environment):

### How to activate virtual environment

---

POSIX	<code>bash</code>	<code>&lt;venv&gt;/bin/activate</code>
-------	-------------------	----------------------------------------

---

fish	<code>source</code>	<code>&lt;venv&gt;/bin/activate.fish</code>
------	---------------------	---------------------------------------------

---

csh/tcsh	<code>source</code>	<code>&lt;venv&gt;/bin/activate.csh</code>
----------	---------------------	--------------------------------------------

---

PowerShell		<code>bin/Activate.ps1</code>
------------	--	-------------------------------

---

Windows		<code>&lt;venv&gt;\Scripts\activate.bat</code>
---------	--	------------------------------------------------

---

PowerShell		<code>&lt;venv&gt;\Scripts\Activate.ps1</code>
------------	--	------------------------------------------------

---

*New in version 3.4:* **fish** and **csh** activation scripts.

*New in version 3.8:* PowerShell activation scripts installed under POSIX for PowerShell Core support.

You don't specifically *need* to activate a virtual environment, as you can just specify the full path to that environment's Python interpreter when invoking Python. Furthermore, all scripts installed in the environment should be runnable without activating it.

In order to achieve this, scripts installed into virtual environments have a “shebang” line which points to the environment's Python interpreter, i.e. `#!/<path-to-venv>/bin/python`. This means that the script will run with that interpreter regardless of the value of **PATH**. On Windows, “shebang” line processing is supported if you have the [Python Launcher for Windows](#) installed. Thus, double-clicking an installed script in a Windows Explorer window should run it with the correct interpreter without the environment needing to be activated or on the **PATH**.

When a virtual environment has been activated, the **VIRTUAL\_ENV** environment variable is set to the path of the environment. Since explicitly activating a virtual environment is not required to use it, **VIRTUAL\_ENV** cannot be relied upon to determine whether a virtual environment is being used.

## Warning

Because scripts installed in environments should not expect the environment to be activated, their shebang lines contain the absolute paths to their environment's interpreters. Because of this, environments are inherently non-portable, in the general case. You should always have a simple means of recreating an environment (for example, if you have a requirements file `requirements.txt`, you can invoke `pip install -r requirements.txt` using the environment's `pip` to install all of the packages needed by the environment). If for any reason you need to move the environment to a new location, you should recreate it at the desired location and delete the one at the old location. If you move an environment because you moved a parent directory of it, you should recreate the environment in its new location. Otherwise, software installed into the environment

may not work as expected.

You can deactivate a virtual environment by typing `deactivate` in your shell. The exact mechanism is platform-specific and is an internal implementation detail (typically, a script or shell function will be used).

## API

The high-level method described above makes use of a simple API which provides mechanisms for third-party virtual environment creators to customize environment creation according to their needs, the `EnvBuilder` class.

```
class venv.EnvBuilder(system_site_packages=False, clear=False,  
symlinks=False, upgrade=False, with_pip=False, prompt=None,  
upgrade_deps=False)
```

The `EnvBuilder` class accepts the following keyword arguments on instantiation:

- `system_site_packages` – a Boolean value indicating that the system Python site-packages should be available to the environment (defaults to `False`).
- `clear` – a Boolean value which, if true, will delete the contents of any existing target directory, before creating the environment.
- `symlinks` – a Boolean value indicating whether to attempt to symlink the Python binary rather than copying.
- `upgrade` – a Boolean value which, if true, will upgrade an existing environment with the running Python - for use when that Python has been upgraded in-place (defaults to `False`).
- `with_pip` – a Boolean value which, if true, ensures pip is installed in the virtual environment. This uses `ensurepip` with the `--default-pip` option.
- `prompt` – a String to be used after virtual environment is activated (defaults to `None` which means directory name of the environment would be used). If the special

string `"."` is provided, the basename of the current directory is used as the prompt.

- `upgrade_deps` – Update the base venv modules to the latest on PyPI

*Changed in version 3.4:* Added the `with_pip` parameter

*New in version 3.6:* Added the `prompt` parameter

*New in version 3.9:* Added the `upgrade_deps` parameter

Creators of third-party virtual environment tools will be free to use the provided `EnvBuilder` class as a base class.

The returned env-builder is an object which has a method, `create`:

`create(env_dir)`

Create a virtual environment by specifying the target directory (absolute or relative to the current directory) which is to contain the virtual environment. The `create` method will either create the environment in the specified directory, or raise an appropriate exception.

The `create` method of the `EnvBuilder` class illustrates the hooks available for subclass customization:

```
def create(self, env_dir):
    """
    Create a virtualized Python environment in
    env_dir is the target directory to create a
    """
    env_dir = os.path.abspath(env_dir)
    context = self.ensure_directories(env_dir)
    self.create_configuration(context)
    self.setup_python(context)
    self.setup_scripts(context)
    self.post_setup(context)
```

Each of the methods `ensure_directories()`, `create_configuration()`, `setup_python()`, `setup_scripts()` and `post_setup()` can be overridden.

`ensure_directories(env_dir)`

Creates the environment directory and all necessary subdirectories that don't already exist, and returns a context object. This context object is just a holder for attributes (such as paths) for use by the other methods. If the `EnvBuilder` is created with the arg `clear=True`, contents of the environment directory will be cleared and then all necessary subdirectories will be recreated.

The returned context object is a `types.SimpleNamespace` with the following attributes:

- `env_dir` - The location of the virtual environment. Used for `__VENV_DIR__` in activation scripts (see `install_scripts()`).
- `env_name` - The name of the virtual environment. Used for `__VENV_NAME__` in activation scripts (see `install_scripts()`).
- `prompt` - The prompt to be used by the activation scripts. Used for `__VENV_PROMPT__` in activation scripts (see `install_scripts()`).
- `executable` - The underlying Python executable used by the virtual environment. This takes into account the case where a virtual environment is created from another virtual environment.
- `inc_path` - The include path for the virtual environment.
- `lib_path` - The purelib path for the virtual environment.
- `bin_path` - The script path for the virtual environment.
- `bin_name` - The name of the script path relative

- to the virtual environment location. Used for `__VENV_BIN_NAME__` in activation scripts (see [install\\_scripts\(\)](#)).
- `env_exe` - The name of the Python interpreter in the virtual environment. Used for `__VENV_PYTHON__` in activation scripts (see [install\\_scripts\(\)](#)).
  - `env_exec_cmd` - The name of the Python interpreter, taking into account filesystem redirections. This can be used to run Python in the virtual environment.

*Changed in version 3.12:* The attribute `lib_path` was added to the context, and the context object was documented.

*Changed in version 3.11:* The `venv` [sysconfig installation scheme](#) is used to construct the paths of the created directories.

`create_configuration(context)`

Creates the `pyenvv.cfg` configuration file in the environment.

`setup_python(context)`

Creates a copy or symlink to the Python executable in the environment. On POSIX systems, if a specific executable `python3.x` was used, symlinks to `python` and `python3` will be created pointing to that executable, unless files with those names already exist.

`setup_scripts(context)`

Installs activation scripts appropriate to the platform into the virtual environment.

`upgrade_dependencies(context)`

Upgrades the core `venv` dependency packages (currently `pip`) in the environment. This is done by

shelling out to the `pip` executable in the environment.

*New in version 3.9.*

*Changed in version 3.12:* `setuptools` is no longer a core `venv` dependency.

`post_setup(context)`

A placeholder method which can be overridden in third party implementations to pre-install packages in the virtual environment or perform other post-creation steps.

*Changed in version 3.7.2:* Windows now uses redirector scripts for `python[w].exe` instead of copying the actual binaries. In 3.7.2 only `setup_python()` does nothing unless running from a build in the source tree.

*Changed in version 3.7.3:* Windows copies the redirector scripts as part of `setup_python()` instead of `setup_scripts()`. This was not the case in 3.7.2. When using symlinks, the original executables will be linked.

In addition, `EnvBuilder` provides this utility method that can be called from `setup_scripts()` or `post_setup()` in subclasses to assist in installing custom scripts into the virtual environment.

`install_scripts(context, path)`

`path` is the path to a directory that should contain subdirectories “common”, “posix”, “nt”, each containing scripts destined for the bin directory in the environment. The contents of “common” and the directory corresponding to `os.name` are copied after some text replacement of placeholders:

- `__VENV_DIR__` is replaced with the absolute path of the environment directory.
- `__VENV_NAME__` is replaced with the environment name (final path segment of

environment directory).

- `__VENV_PROMPT__` is replaced with the prompt (the environment name surrounded by parentheses and with a following space)
- `__VENV_BIN_NAME__` is replaced with the name of the bin directory (either `bin` or `Scripts`).
- `__VENV_PYTHON__` is replaced with the absolute path of the environment's executable.

The directories are allowed to exist (for when an existing environment is being upgraded).

There is also a module-level convenience function:

```
venv.create(env_dir, system_site_packages=False, clear=False,  
symlinks=False, with_pip=False, prompt=None, upgrade_deps=False)
```

Create an **EnvBuilder** with the given keyword arguments, and call its **create()** method with the *env\_dir* argument.

*New in version 3.3.*

*Changed in version 3.4:* Added the `with_pip` parameter

*Changed in version 3.6:* Added the `prompt` parameter

*Changed in version 3.9:* Added the `upgrade_deps` parameter

## An example of extending **EnvBuilder**

The following script shows how to extend **EnvBuilder** by implementing a subclass which installs `setuptools` and `pip` into a created virtual environment:

```
import os  
import os.path  
from subprocess import Popen, PIPE  
import sys  
from threading import Thread  
from urllib.parse import urlparse
```

```
from urllib.request import urlretrieve
import venv
```

```
class ExtendedEnvBuilder(venv.EnvBuilder):
```

```
    """
```

```
    This builder installs setuptools and pip so that you can
    easily install other packages into the created virtual
```

```
    :param nodist: If true, setuptools and pip are not installed into the
                   created virtual environment.
```

```
    :param nopip: If true, pip is not installed into the created
                  virtual environment.
```

```
    :param progress: If setuptools or pip are installed, the
                      installation can be monitored by passing a
                      callable. If specified, it is called with the
                      arguments: a string indicating some progress
                      context indicating where the string should be
                      The context argument can have one of the values:
                      'main', indicating that it is called from the
                      itself, and 'stdout' and 'stderr', indicating
                      by reading lines from the output stream
                      which is used to install the app.
```

```
    If a callable is not specified, default progress information
    is output to sys.stderr.
```

```
    """
```

```
    def __init__(self, *args, **kwargs):
```

```
        self.nodist = kwargs.pop('nodist', False)
```

```
        self.nopip = kwargs.pop('nopip', False)
```

```
        self.progress = kwargs.pop('progress', None)
```

```
        self.verbose = kwargs.pop('verbose', False)
```

```
        super().__init__(*args, **kwargs)
```

```
    def post_setup(self, context):
```

```
        """
```

```
        Set up any packages which need to be pre-installed into the
        virtual environment being created.
```

```

:param context: The information for the virtual
                creation request being processed

# zipapp — Manage executable Python zip archives

*New in version 3.5.*

**Source code:** [Lib/zipapp.py](https://github.com/python/cpython/tree/3.12/Lib/zipapp.py) [https://github.com/python/cpython/tree/3.12/Lib/zipapp.py]

---

This module provides tools to manage the creation of zip files containing Python code, which can be [executed directly by the Python interpreter](#). The module provides both a [Command-Line Interface](#) and a [Python API](#).

## Basic Example

The following example shows how the [Command-Line Interface](#) can be used to create an executable archive from a directory containing Python code. When run, the archive will execute the `main` function from the module `myapp` in the archive.

```
$ python -m zipapp myapp -m "myapp:main"  
$ python myapp.pyz  
<output from myapp>
```

## Command-Line Interface

When called as a program from the command line, the following form is used:

```
$ python -m zipapp source [options]
```

If *source* is a directory, this will create an archive from the contents of *source*. If *source* is a file, it should be an archive, and it will be copied to the target archive (or the contents of its shebang line will

be displayed if the `-info` option is specified).

The following options are understood:

`-o <output>`, `--output = <output>`

Write the output to a file named *output*. If this option is not specified, the output filename will be the same as the input *source*, with the extension `.pyz` added. If an explicit filename is given, it is used as is (so a `.pyz` extension should be included if required).

An output filename must be specified if the *source* is an archive (and in that case, *output* must not be the same as *source*).

`-p <interpreter>`, `--python = <interpreter>`

Add a `#!` line to the archive specifying *interpreter* as the command to run. Also, on POSIX, make the archive executable. The default is to write no `#!` line, and not make the file executable.

`-m <mainfn>`, `--main = <mainfn>`

Write a `__main__.py` file to the archive that executes *mainfn*. The *mainfn* argument should have the form “`pkg.mod:fn`”, where “`pkg.mod`” is a package/module in the archive, and “`fn`” is a callable in the given module. The `__main__.py` file will execute that callable.

`--main` cannot be specified when copying an archive.

`-c`, `--compress`

Compress files with the deflate method, reducing the size of the output file. By default, files are stored uncompressed in the archive.

`--compress` has no effect when copying an archive.

*New in version 3.7.*

--info

Display the interpreter embedded in the archive, for diagnostic purposes. In this case, any other options are ignored and SOURCE must be an archive, not a directory.

-h, --help

Print a short usage message and exit.

## Python API

The module defines two convenience functions:

`zipapp.create_archive(source, target=None, interpreter=None, main=None, filter=None, compressed=False)`

Create an application archive from *source*. The source can be any of the following:

- The name of a directory, or a [path-like object](#) referring to a directory, in which case a new application archive will be created from the content of that directory.
- The name of an existing application archive file, or a [path-like object](#) referring to such a file, in which case the file is copied to the target (modifying it to reflect the value given for the *interpreter* argument). The file name should include the `.pyz` extension, if required.
- A file object open for reading in bytes mode. The content of the file should be an application archive, and the file object is assumed to be positioned at the start of the archive.

The *target* argument determines where the resulting archive will be written:

- If it is the name of a file, or a [path-like object](#), the archive will be written to that file.
- If it is an open file object, the archive will be written to that file object, which must be open for writing in bytes mode.
- If the target is omitted (or `None`), the source must be a

directory and the target will be a file with the same name as the source, with a `.pyz` extension added.

The *interpreter* argument specifies the name of the Python interpreter with which the archive will be executed. It is written as a “shebang” line at the start of the archive. On POSIX, this will be interpreted by the OS, and on Windows it will be handled by the Python launcher. Omitting the *interpreter* results in no shebang line being written. If an interpreter is specified, and the target is a filename, the executable bit of the target file will be set.

The *main* argument specifies the name of a callable which will be used as the main program for the archive. It can only be specified if the source is a directory, and the source does not already contain a `__main__.py` file. The *main* argument should take the form “pkg.module:callable” and the archive will be run by importing “pkg.module” and executing the given callable with no arguments. It is an error to omit *main* if the source is a directory and does not contain a `__main__.py` file, as otherwise the resulting archive would not be executable.

The optional *filter* argument specifies a callback function that is passed a Path object representing the path to the file being added (relative to the source directory). It should return `True` if the file is to be added.

The optional *compressed* argument determines whether files are compressed. If set to `True`, files in the archive are compressed with the deflate method; otherwise, files are stored uncompressed. This argument has no effect when copying an existing archive.

If a file object is specified for *source* or *target*, it is the caller’s responsibility to close it after calling `create_archive`.

When copying an existing archive, file objects supplied only need `read` and `readline`, or `write` methods. When creating an archive from a directory, if the target is a file object it will be passed to the `zipfile.ZipFile` class, and

must supply the methods needed by that class.

*New in version 3.7:* Added the *filter* and *compressed* arguments.

`zipapp.get_interpreter(archive)`

Return the interpreter specified in the `#!` line at the start of the archive. If there is no `#!` line, return `None`. The *archive* argument can be a filename or a file-like object open for reading in bytes mode. It is assumed to be at the start of the archive.

## Examples

Pack up a directory into an archive, and run it.

```
$ python -m zipapp myapp
$ python myapp.pyz
<output from myapp>
```

The same can be done using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('myapp', 'myapp.pyz')
```

To make the application directly executable on POSIX, specify an interpreter to use.

```
$ python -m zipapp myapp -p "/usr/bin/env python"
$ ./myapp.pyz
<output from myapp>
```

To replace the shebang line on an existing archive, create a modified archive using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('old_archive.pyz', 'new_archive.pyz')
```

To update the file in place, do the replacement in memory using a `BytesIO` object, and then overwrite the source afterwards. Note that there is a risk when overwriting a file in place that an error

will result in the loss of the original file. This code does not protect against such errors, but production code should do so. Also, this method will only work if the archive fits in memory:

```
>>> import zipapp
>>> import io
>>> temp = io.BytesIO()
>>> zipapp.create_archive('myapp.pyz', temp, '/usr/bin/p
>>> with open('myapp.pyz', 'wb') as f:
>>>     f.write(temp.getvalue())
```

## Specifying the Interpreter

Note that if you specify an interpreter and then distribute your application archive, you need to ensure that the interpreter used is portable. The Python launcher for Windows supports most common forms of POSIX `#!` line, but there are other issues to consider:

- If you use “`/usr/bin/env python`” (or other forms of the “python” command, such as “`/usr/bin/python`”), you need to consider that your users may have either Python 2 or Python 3 as their default, and write your code to work under both versions.
- If you use an explicit version, for example “`/usr/bin/env python3`” your application will not work for users who do not have that version. (This may be what you want if you have not made your code Python 2 compatible).
- There is no way to say “python X.Y or later”, so be careful of using an exact version like “`/usr/bin/env python3.4`” as you will need to change your shebang line for users of Python 3.5, for example.

Typically, you should use an “`/usr/bin/env python2`” or “`/usr/bin/env python3`”, depending on whether your code is written for Python 2 or 3.

## Creating Standalone Applications with zipapp

Using the [zipapp](#) module, it is possible to create self-contained Python programs, which can be distributed to end users who only need to have a suitable version of Python installed on their system. The key to doing this is to bundle all of the application's dependencies into the archive, along with the application code.

The steps to create a standalone archive are as follows:

1. Create your application in a directory as normal, so you have a `myapp` directory containing a `__main__.py` file, and any supporting application code.
2. Install all of your application's dependencies into the `myapp` directory, using `pip`:

```
$ python -m pip install -r requirements.txt --target
```

(this assumes you have your project requirements in a `requirements.txt` file - if not, you can just list the dependencies manually on the `pip` command line).

3. Package the application using:

```
$ python -m zipapp -p "interpreter" myapp
```

This will produce a standalone executable, which can be run on any machine with the appropriate interpreter available. See [Specifying the Interpreter](#) for details. It can be shipped to users as a single file.

On Unix, the `myapp.pyz` file is executable as it stands. You can rename the file to remove the `.pyz` extension if you prefer a “plain” command name. On Windows, the `myapp.pyz[w]` file is executable by virtue of the fact that the Python interpreter registers the `.pyz` and `.pyzw` file extensions when installed.

## Caveats

If your application depends on a package that includes a C extension, that package cannot be run from a zip file (this is an OS limitation, as executable code must be present in the filesystem for the OS loader to load it). In this case, you can exclude that

dependency from the zipfile, and either require your users to have it installed, or ship it alongside your zipfile and add code to your `__main__.py` to include the directory containing the unzipped module in `sys.path`. In this case, you will need to make sure to ship appropriate binaries for your target architecture(s) (and potentially pick the correct version to add to `sys.path` at runtime, based on the user's machine).

## The Python Zip Application Archive Format

Python has been able to execute zip files which contain a `__main__.py` file since version 2.6. In order to be executed by Python, an application archive simply has to be a standard zip file containing a `__main__.py` file which will be run as the entry point for the application. As usual for any Python script, the parent of the script (in this case the zip file) will be placed on `sys.path` and thus further modules can be imported from the zip file.

The zip file format allows arbitrary data to be prepended to a zip file. The zip application format uses this ability to prepend a standard POSIX “shebang” line to the file (`#!/path/to/interpreter`).

Formally, the Python zip application format is therefore:

1. An optional shebang line, containing the characters `b'#!'` followed by an interpreter name, and then a newline (`b'\n'`) character. The interpreter name can be anything acceptable to the OS “shebang” processing, or the Python launcher on Windows. The interpreter should be encoded in UTF-8 on Windows, and in `sys.getfilesystemencoding()` on POSIX.
2. Standard zipfile data, as generated by the `zipfile` module. The zipfile content *must* include a file called `__main__.py` (which must be in the “root” of the zipfile - i.e., it cannot be in a subdirectory). The zipfile data can be compressed or uncompressed.

If an application archive has a shebang line, it may have the

executable bit set on POSIX systems, to allow it to be executed directly.

There is no requirement that the tools in this module are used to create application archives - the module is a convenience, but archives in the above format created by any means are acceptable to Python.

# Python Runtime Services

The modules described in this chapter provide a wide range of services related to the Python interpreter and its interaction with its environment. Here's an overview:

- **sys** — System-specific parameters and functions
- **sys.monitoring** — Execution event monitoring
  - Tool identifiers
    - Registering and using tools
  - Events
    - Local events
    - Ancillary events
    - Other events
    - The `STOP_ITERATION` event
  - Turning events on and off
    - Setting events globally
    - Per code object events
    - Disabling events
  - Registering callback functions
    - Callback function arguments
- **sysconfig** — Provide access to Python's configuration information
  - Configuration variables
  - Installation paths
  - User scheme
    - **posix\_user**

- `nt_user`
  - `osx_framework_user`
- Home scheme
  - `posix_home`
- Prefix scheme
  - `posix_prefix`
  - `nt`
- Installation path functions
- Other functions
- Using `sysconfig` as a script
- **`builtins`** — Built-in objects
- **`__main__`** — Top-level code environment
  - `__name__ == '__main__'`
    - What is the “top-level code environment”?
    - Idiomatic Usage
    - Packaging Considerations
  - `__main__.py` in Python Packages
    - Idiomatic Usage
  - `import __main__`
- **`warnings`** — Warning control
  - Warning Categories
  - The Warnings Filter
    - Describing Warning Filters
    - Default Warning Filter
    - Overriding the default filter
  - Temporarily Suppressing Warnings
  - Testing Warnings

- Updating Code For New Versions of Dependencies
- Available Functions
- Available Context Managers

- **dataclasses** — Data Classes

- Module contents
- Post-init processing
- Class variables
- Init-only variables
- Frozen instances
- Inheritance
- Re-ordering of keyword-only parameters in `__init__()`
- Default factory functions
- Mutable default values
- Descriptor-typed fields

- **contextlib** — Utilities for **with**-statement contexts

- Utilities
- Examples and Recipes
  - Supporting a variable number of context managers
  - Catching exceptions from `__enter__` methods
  - Cleaning up in an `__enter__` implementation
  - Replacing any use of **try-finally** and flag variables
  - Using a context manager as a function decorator
- Single use, reusable and reentrant context managers
  - Reentrant context managers
  - Reusable context managers

- **abc** — Abstract Base Classes

- **atexit** — Exit handlers

- **atexit** Example

- **traceback** — Print or retrieve a stack traceback

- **TracebackException** Objects
- **StackSummary** Objects
- **FrameSummary** Objects
- Traceback Examples
- **\_\_future\_\_** — Future statement definitions
- **gc** — Garbage Collector interface
- **inspect** — Inspect live objects
  - Types and members
  - Retrieving source code
  - Introspecting callables with the Signature object
  - Classes and functions
  - The interpreter stack
  - Fetching attributes statically
  - Current State of Generators, Coroutines, and Asynchronous Generators
  - Code Objects Bit Flags
  - Buffer flags
  - Command Line Interface
- **site** — Site-specific configuration hook
  - **sitecustomize**
  - **usercustomize**
  - Readline configuration
  - Module contents
  - Command Line Interface

# sys — System-specific parameters and functions

---

This module provides access to some variables used or maintained by the interpreter and to functions that interact strongly with the interpreter. It is always available.

## sys.abiflags

On POSIX systems where Python was built with the standard configure script, this contains the ABI flags as specified by [PEP 3149](https://peps.python.org/pep-3149/) [https://peps.python.org/pep-3149/].

*Changed in version 3.8:* Default flags became an empty string (m flag for pymalloc has been removed).

*New in version 3.2.*

## sys.addaudithook(*hook*)

Append the callable *hook* to the list of active auditing hooks for the current (sub)interpreter.

When an auditing event is raised through the `sys.audit()` function, each hook will be called in the order it was added with the event name and the tuple of arguments. Native hooks added by `PySys_AddAuditHook()` are called first, followed by hooks added in the current (sub)interpreter. Hooks can then log the event, raise an exception to abort the operation, or terminate the process entirely.

Note that audit hooks are primarily for collecting information about internal or otherwise unobservable actions, whether by Python or libraries written in Python. They are not suitable for implementing a “sandbox”. In particular, malicious code can trivially disable or bypass hooks added using this

function. At a minimum, any security-sensitive hooks must be added using the C API `PySys_AddAuditHook()` before initialising the runtime, and any modules allowing arbitrary memory modification (such as `ctypes`) should be completely removed or closely monitored.

Calling `sys.addaudithook()` will itself raise an auditing event named `sys.addaudithook` with no arguments. If any existing hooks raise an exception derived from `RuntimeError`, the new hook will not be added and the exception suppressed. As a result, callers cannot assume that their hook has been added unless they control all existing hooks.

See the [audit events table](#) for all events raised by CPython, and [PEP 578](#) [<https://peps.python.org/pep-0578/>] for the original design discussion.

*New in version 3.8.*

*Changed in version 3.8.1:* Exceptions derived from `Exception` but not `RuntimeError` are no longer suppressed.

**CPython implementation detail:** When tracing is enabled (see `settrace()`), Python hooks are only traced if the callable has a `__cantrace__` member that is set to a true value. Otherwise, trace functions will skip the hook.

## `sys.argv`

The list of command line arguments passed to a Python script. `argv[0]` is the script name (it is operating system dependent whether this is a full pathname or not). If the command was executed using the `-c` command line option to the interpreter, `argv[0]` is set to the string `'-c'`. If no script name was passed to the Python interpreter, `argv[0]` is the empty string.

To loop over the standard input, or the list of files given on the command line, see the [fileinput](#) module.

See also `sys.orig_argv`.

## Note

On Unix, command line arguments are passed by bytes from OS. Python decodes them with filesystem encoding and “surrogateescape” error handler. When you need original bytes, you can get it by `[os.fsencode(arg) for arg in sys.argv]`.

`sys.audit(event, *args)`

Raise an auditing event and trigger any active auditing hooks. *event* is a string identifying the event, and *args* may contain optional arguments with more information about the event. The number and types of arguments for a given event are considered a public and stable API and should not be modified between releases.

For example, one auditing event is named `os.chdir`. This event has one argument called *path* that will contain the requested new working directory.

`sys.audit()` will call the existing auditing hooks, passing the event name and arguments, and will re-raise the first exception from any hook. In general, if an exception is raised, it should not be handled and the process should be terminated as quickly as possible. This allows hook implementations to decide how to respond to particular events: they can merely log the event or abort the operation by raising an exception.

Hooks are added using the `sys.addaudithook()` or `PySys_AddAuditHook()` functions.

The native equivalent of this function is `PySys_Audit()`. Using the native function is preferred when possible.

See the [audit events table](#) for all events raised by CPython.

*New in version 3.8.*

#### `sys.base_exec_prefix`

Set during Python startup, before `site.py` is run, to the same value as `exec_prefix`. If not running in a [virtual environment](#), the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of `prefix` and `exec_prefix` will be changed to point to the virtual environment, whereas `base_prefix` and `base_exec_prefix` will remain pointing to the base Python installation (the one which the virtual environment was created from).

*New in version 3.3.*

#### `sys.base_prefix`

Set during Python startup, before `site.py` is run, to the same value as `prefix`. If not running in a [virtual environment](#), the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of `prefix` and `exec_prefix` will be changed to point to the virtual environment, whereas `base_prefix` and `base_exec_prefix` will remain pointing to the base Python installation (the one which the virtual environment was created from).

*New in version 3.3.*

#### `sys.byteorder`

An indicator of the native byte order. This will have the value `'big'` on big-endian (most-significant byte first) platforms, and `'little'` on little-endian (least-significant byte first) platforms.

#### `sys.builtin_module_names`

A tuple of strings containing the names of all modules that are compiled into this Python interpreter. (This information is not available in any other way — `modules.keys()` only lists the imported modules.)

See also the `sys.stdlib_module_names` list.

### `sys.call_tracing(func, args)`

Call `func(*args)`, while tracing is enabled. The tracing state is saved, and restored afterwards. This is intended to be called from a debugger from a checkpoint, to recursively debug some other code.

### `sys.copyright`

A string containing the copyright pertaining to the Python interpreter.

### `sys.clear_type_cache()`

Clear the internal type cache. The type cache is used to speed up attribute and method lookups. Use the function *only* to drop unnecessary references during reference leak debugging.

This function should be used for internal and specialized purposes only.

### `sys.current_frames()`

Return a dictionary mapping each thread's identifier to the topmost stack frame currently active in that thread at the time the function is called. Note that functions in the `traceback` module can build the call stack given such a frame.

This is most useful for debugging deadlock: this function does not require the deadlocked threads' cooperation, and such threads' call stacks are frozen for as long as they remain deadlocked. The frame returned for a non-deadlocked thread may bear no relationship to that thread's current activity by the time calling code examines the frame.

This function should be used for internal and specialized purposes only.

Raises an `auditing event` `sys._current_frames` with no arguments.

## `sys._current_exceptions()`

Return a dictionary mapping each thread's identifier to the topmost exception currently active in that thread at the time the function is called. If a thread is not currently handling an exception, it is not included in the result dictionary.

This is most useful for statistical profiling.

This function should be used for internal and specialized purposes only.

Raises an [auditing event](#) `sys._current_exceptions` with no arguments.

*Changed in version 3.12:* Each value in the dictionary is now a single exception instance, rather than a 3-tuple as returned from `sys.exc_info()`.

## `sys.breakpointhook()`

This hook function is called by built-in [breakpoint\(\)](#). By default, it drops you into the [pdb](#) debugger, but it can be set to any other function so that you can choose which debugger gets used.

The signature of this function is dependent on what it calls. For example, the default binding (e.g. `pdb.set_trace()`) expects no arguments, but you might bind it to a function that expects additional arguments (positional and/or keyword). The built-in `breakpoint()` function passes its `*args` and `**kws` straight through. Whatever `breakpointhooks()` returns is returned from `breakpoint()`.

The default implementation first consults the environment variable [PYTHONBREAKPOINT](#). If that is set to `"0"` then this function returns immediately; i.e. it is a no-op. If the environment variable is not set, or is set to the empty string, `pdb.set_trace()` is called. Otherwise this variable should name a function to run, using Python's dotted-import nomenclature, e.g.

`package.subpackage.module.function`. In this case, `package.subpackage.module` would be imported and the resulting module must have a callable named `function()`. This is run, passing in `*args` and `**kwargs`, and whatever `function()` returns, `sys.breakpointhook()` returns to the built-in `breakpoint()` function.

Note that if anything goes wrong while importing the callable named by `PYTHONBREAKPOINT`, a `RuntimeWarning` is reported and the breakpoint is ignored.

Also note that if `sys.breakpointhook()` is overridden programmatically, `PYTHONBREAKPOINT` is *not* consulted.

*New in version 3.7.*

## `sys.debugmallocstats()`

Print low-level information to `stderr` about the state of CPython's memory allocator.

If Python is [built in debug mode](#) (`configure --with-pydebug option`), it also performs some expensive internal consistency checks.

*New in version 3.3.*

**CPython implementation detail:** This function is specific to CPython. The exact output format is not defined here, and may change.

## `sys.dllhandle`

Integer specifying the handle of the Python DLL.

[Availability](#): Windows.

## `sys.displayhook(value)`

If `value` is not `None`, this function prints `repr(value)` to `sys.stdout`, and saves `value` in `builtins._`. If `repr(value)` is not encodable to `sys.stdout.encoding` with `sys.stdout.errors` error handler (which is probably

'strict'), encode it to `sys.stdout.encoding` with 'backslashreplace' error handler.

`sys.displayhook` is called on the result of evaluating an [expression](#) entered in an interactive Python session. The display of these values can be customized by assigning another one-argument function to `sys.displayhook`.

Pseudo-code:

```
def displayhook(value):
    if value is None:
        return
    # Set '_' to None to avoid recursion
    builtins._ = None
    text = repr(value)
    try:
        sys.stdout.write(text)
    except UnicodeEncodeError:
        bytes = text.encode(sys.stdout.encoding, 'b')
        if hasattr(sys.stdout, 'buffer'):
            sys.stdout.buffer.write(bytes)
        else:
            text = bytes.decode(sys.stdout.encoding)
            sys.stdout.write(text)
    sys.stdout.write("\n")
    builtins._ = value
```

*Changed in version 3.2:* Use 'backslashreplace' error handler on [UnicodeEncodeError](#).

`sys.dont_write_bytecode`

If this is true, Python won't try to write `.pyc` files on the import of source modules. This value is initially set to `True` or `False` depending on the `-B` command line option and the [PYTHONDONTWRITEBYTECODE](#) environment variable, but you can set it yourself to control bytecode file generation.

`sys.emsripten_info`

A [named tuple](#) holding information about the environment on the *wasm32-emscrip*ten platform. The named tuple is provisional and may change in the future.

`_emscripten_info.emscripten_version`

Emscripten version as tuple of ints (major, minor, micro), e.g. `(3, 1, 8)`.

`_emscripten_info.runtime`

Runtime string, e.g. browser user agent, `'Node.js v14.18.2'`, or `'UNKNOWN'`.

`_emscripten_info.pthreads`

`True` if Python is compiled with Emscripten pthreads support.

`_emscripten_info.shared_memory`

`True` if Python is compiled with shared memory support.

[Availability](#): Emscripten.

*New in version 3.11.*

`sys.pycache_prefix`

If this is set (not `None`), Python will write bytecode-cache `.pyc` files to (and read them from) a parallel directory tree rooted at this directory, rather than from `__pycache__` directories in the source code tree. Any `__pycache__` directories in the source code tree will be ignored and new `.pyc` files written within the pycache prefix. Thus if you use [compileall](#) as a pre-build step, you must ensure you run it with the same pycache prefix (if any) that you will use at runtime.

A relative path is interpreted relative to the current working directory.

This value is initially set based on the value of the [-x](#)

`pycache_prefix=PATH` command-line option or the `PYTHONPYCACHEPREFIX` environment variable (command-line takes precedence). If neither are set, it is `None`.

*New in version 3.8.*

`sys.excepthook(type, value, traceback)`

This function prints out a given traceback and exception to `sys.stderr`.

When an exception other than `SystemExit` is raised and uncaught, the interpreter calls `sys.excepthook` with three arguments, the exception class, exception instance, and a traceback object. In an interactive session this happens just before control is returned to the prompt; in a Python program this happens just before the program exits. The handling of such top-level exceptions can be customized by assigning another three-argument function to `sys.excepthook`.

Raise an auditing event `sys.excepthook` with arguments `hook, type, value, traceback` when an uncaught exception occurs. If no hook has been set, `hook` may be `None`. If any hook raises an exception derived from `RuntimeError` the call to the hook will be suppressed. Otherwise, the audit hook exception will be reported as unraisable and `sys.excepthook` will be called.

### See also

The `sys.unraisablehook()` function handles unraisable exceptions and the `threading.excepthook()` function handles exception raised by `threading.Thread.run()`.

`sys._breakpointhook_`  
`sys._displayhook_`  
`sys._excepthook_`  
`sys._unraisablehook_`

These objects contain the original values of `breakpointhook`, `displayhook`, `excepthook`, and `unraisablehook` at the start of the program. They are saved so that `breakpointhook`, `displayhook` and `excepthook`, `unraisablehook` can be restored in case they happen to get replaced with broken or alternative objects.

*New in version 3.7:* `__breakpointhook__`

*New in version 3.8:* `__unraisablehook__`

## `sys.exception()`

This function, when called while an exception handler is executing (such as an `except` or `except*` clause), returns the exception instance that was caught by this handler. When exception handlers are nested within one another, only the exception handled by the innermost handler is accessible.

If no exception handler is executing, this function returns `None`.

*New in version 3.11.*

## `sys.exc_info()`

This function returns the old-style representation of the handled exception. If an exception `e` is currently handled (so `exception()` would return `e`), `exc_info()` returns the tuple `(type(e), e, e.__traceback__)`. That is, a tuple containing the type of the exception (a subclass of `BaseException`), the exception itself, and a `traceback` object which typically encapsulates the call stack at the point where the exception last occurred.

If no exception is being handled anywhere on the stack, this function return a tuple containing three `None` values.

*Changed in version 3.11:* The `type` and `traceback` fields are now derived from the `value` (the exception instance), so when an exception is modified while it is being handled, the

changes are reflected in the results of subsequent calls to `exc_info()`.

#### `sys.exec_prefix`

A string giving the site-specific directory prefix where the platform-dependent Python files are installed; by default, this is also `'/usr/local'`. This can be set at build time with the `--exec-prefix` argument to the **configure** script. Specifically, all configuration files (e.g. the `pyconfig.h` header file) are installed in the directory `exec_prefix/lib/pythonX.Y/config`, and shared library modules are installed in `exec_prefix/lib/pythonX.Y/lib-dynload`, where `X.Y` is the version number of Python, for example `3.2`.

#### Note

If a [virtual environment](#) is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via `base_exec_prefix`.

#### `sys.executable`

A string giving the absolute path of the executable binary for the Python interpreter, on systems where this makes sense. If Python is unable to retrieve the real path to its executable, `sys.executable` will be an empty string or `None`.

#### `sys.exit([arg])`

Raise a **SystemExit** exception, signaling an intention to exit the interpreter.

The optional argument `arg` can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered “successful termination” and any nonzero value is considered “abnormal termination” by shells and the like. Most systems require it to be in the range 0–127, and produce undefined results otherwise. Some systems have

a convention for assigning specific meanings to specific exit codes, but these are generally underdeveloped; Unix programs generally use 2 for command line syntax errors and 1 for all other kind of errors. If another type of object is passed, `None` is equivalent to passing zero, and any other object is printed to `stderr` and results in an exit code of 1. In particular, `sys.exit("some error message")` is a quick way to exit a program when an error occurs.

Since `exit()` ultimately “only” raises an exception, it will only exit the process when called from the main thread, and the exception is not intercepted. Cleanup actions specified by finally clauses of `try` statements are honored, and it is possible to intercept the exit attempt at an outer level.

*Changed in version 3.6:* If an error occurs in the cleanup after the Python interpreter has caught `SystemExit` (such as an error flushing buffered data in the standard streams), the exit status is changed to 120.

## sys.flags

The `named tuple` `flags` exposes the status of command line flags. The attributes are read only.

<code>flags.debug</code>
<code>flags.inspect</code>
<code>flags.interactive</code>
<code>flags.isolated</code>
<code>flags.optimize</code>
<code>flags.dont_write_bytecode</code>
<code>flags.no_user_site</code>
<code>flags.no_site</code>
<code>flags.ignore_environment</code>
<code>flags.verbose</code>
<code>flags.bytes_warning</code>
<code>flags.quiet</code>
<code>flags.hash_randomization</code>
<code>flags.isdev (Python Development Mode)</code>
<code>flags.utf8_mode</code>
<code>flags.safe_path</code>

`flags.int_max_str_digits` (integer string conversion length limitation)

---

`flags.warn_default_encoding`

---

*Changed in version 3.2:* Added `quiet` attribute for the new `-q` flag.

*New in version 3.2.3:* The `hash_randomization` attribute.

*Changed in version 3.3:* Removed obsolete `division_warning` attribute.

*Changed in version 3.4:* Added `isolated` attribute for `-I` `isolated` flag.

*Changed in version 3.7:* Added the `dev_mode` attribute for the new [Python Development Mode](#) and the `utf8_mode` attribute for the new `-X utf8` flag.

*Changed in version 3.10:* Added `warn_default_encoding` attribute for `-X warn_default_encoding` flag.

*Changed in version 3.11:* Added the `safe_path` attribute for `-P` option.

*Changed in version 3.11:* Added the `int_max_str_digits` attribute.

## `sys.float_info`

A [named tuple](#) holding information about the float type. It contains low level information about the precision and internal representation. The values correspond to the various floating-point constants defined in the standard header file `float.h` for the ‘C’ programming language; see section 5.2.4.2.2 of the 1999 ISO/IEC C standard [\[C99\]](#), ‘Characteristics of floating types’, for details.

~~`sys.float_info`~~

---

~~`sys.float_info`~~ `sys.float_info` is a `namedtuple` with the following attributes: `epsilon` is the difference between 1.0 and the least value greater than 1.0 that is representable as a float.

See also [math.ulp\(\)](#).

---

~~The `float_info.dig`~~ number of decimal digits that can be faithfully represented in a float; see below.

~~The `float_info.radix`~~ the number of base-`radix` digits in the significand of a float.

~~The `float_info.max`~~ representable positive finite float.

~~The `float_info.min`~~ integer `e` such that `radix**(e-1)` is a representable finite float.

~~The `float_info_10`~~ integer `e` such that `10**e` is in the range of representable finite floats.

~~The `float_info.min`~~ representable positive *normalized* float.

Use `math.ulp(0.0)` to get the smallest positive *denormalized* representable float.

~~The `float_info.min`~~ integer `e` such that `radix**(e-1)` is a normalized float.

~~The `float_info_10`~~ integer `e` such that `10**e` is a normalized float.

~~The `float_info`~~ exponent representation.

~~The `float_info`~~ representing the rounding mode for floating-point arithmetic. This reflects the value of the system

`FLT_ROUND` macro at interpreter startup time:

- -1: indeterminable
- 0: toward zero
- 1: to nearest
- 2: toward positive infinity
- 3: toward negative infinity

All other values for `FLT_ROUND` characterize implementation-defined rounding behavior.

### Attributes of the `float_info` named tuple

The attribute `sys.float_info.dig` needs further explanation. If `s` is any string representing a decimal number with at most `sys.float_info.dig` significant digits, then converting `s` to a float and back again will recover a string representing the same decimal value:

```
>>> import sys
>>> sys.float_info.dig
15
>>> s = '3.14159265358979'      # decimal string with
>>> format(float(s), '.15g')    # convert to float and
```

```
'3.14159265358979'
```

But for strings with more than `sys.float_info.dig` significant digits, this isn't always true:

```
>>> s = '9876543211234567'      # 16 significant digits
>>> format(float(s), '.16g')    # conversion changes
'9876543211234568'
```

### `sys.float_repr_style`

A string indicating how the `repr()` function behaves for floats. If the string has value `'short'` then for a finite float `x`, `repr(x)` aims to produce a short string with the property that `float(repr(x)) == x`. This is the usual behaviour in Python 3.1 and later. Otherwise, `float_repr_style` has value `'legacy'` and `repr(x)` behaves in the same way as it did in versions of Python prior to 3.1.

*New in version 3.1.*

### `sys.getallocatedblocks()`

Return the number of memory blocks currently allocated by the interpreter, regardless of their size. This function is mainly useful for tracking and debugging memory leaks. Because of the interpreter's internal caches, the result can vary from call to call; you may have to call `_clear_type_cache()` and `gc.collect()` to get more predictable results.

If a Python build or implementation cannot reasonably compute this information, `getallocatedblocks()` is allowed to return 0 instead.

*New in version 3.4.*

### `sys.getunicodeinternedsize()`

Return the number of unicode objects that have been interned.

*New in version 3.12.*

`sys.getandroidapilevel()`

Return the build time API version of Android as an integer.

[Availability](#): Android.

*New in version 3.7.*

`sys.getdefaultencoding()`

Return the name of the current default string encoding used by the Unicode implementation.

`sys.getdlopenflags()`

Return the current value of the flags that are used for `dlopen()` calls. Symbolic names for the flag values can be found in the `os` module (`RTLD_XXX` constants, e.g. `os.RTLD_LAZY`).

[Availability](#): Unix.

`sys.getfilesystemencoding()`

Get the [filesystem encoding](#): the encoding used with the [filesystem error handler](#) to convert between Unicode filenames and bytes filenames. The filesystem error handler is returned from `getfilesystemencodeerrors()`.

For best compatibility, `str` should be used for filenames in all cases, although representing filenames as bytes is also supported. Functions accepting or returning filenames should support either `str` or bytes and internally convert to the system's preferred representation.

`os.fsencode()` and `os.fsdecode()` should be used to ensure that the correct encoding and errors mode are used.

The [filesystem encoding and error handler](#) are configured at Python startup by the `PyConfig_Read()` function: see [filesystem\\_encoding](#) and [filesystem\\_errors](#)

members of `PyConfig`.

*Changed in version 3.2:* `getfilesystemencoding()` result cannot be `None` anymore.

*Changed in version 3.6:* Windows is no longer guaranteed to return `'mbcs'`. See [PEP 529](https://peps.python.org/pep-0529/) [https://peps.python.org/pep-0529/] and `_enablelegacywindowsfsencoding()` for more information.

*Changed in version 3.7:* Return `'utf-8'` if the [Python UTF-8 Mode](#) is enabled.

`sys.getfilesystemencodeerrors()`

Get the [filesystem error handler](#): the error handler used with the [filesystem encoding](#) to convert between Unicode filenames and bytes filenames. The filesystem encoding is returned from `getfilesystemencoding()`.

`os.fsencode()` and `os.fsdecode()` should be used to ensure that the correct encoding and errors mode are used.

The [filesystem encoding](#) and [error handler](#) are configured at Python startup by the `PyConfig_Read()` function: see [filesystem\\_encoding](#) and [filesystem\\_errors](#) members of `PyConfig`.

*New in version 3.6.*

`sys.get_int_max_str_digits()`

Returns the current value for the [integer string conversion length limitation](#). See also `set_int_max_str_digits()`.

*New in version 3.11.*

`sys.getrefcount(object)`

Return the reference count of the *object*. The count returned is generally one higher than you might expect, because it includes the (temporary) reference as an argument to

`getrefcount()`.

Note that the returned value may not actually reflect how many references to the object are actually held. For example, some objects are “immortal” and have a very high refcount that does not reflect the actual number of references. Consequently, do not rely on the returned value to be accurate, other than a value of 0 or 1.

*Changed in version 3.12:* Immortal objects have very large refcounts that do not match the actual number of references to the object.

`sys.getrecursionlimit()`

Return the current value of the recursion limit, the maximum depth of the Python interpreter stack. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python. It can be set by `setrecursionlimit()`.

`sys.getsizeof(object[, default])`

Return the size of an object in bytes. The object can be any type of object. All built-in objects will return correct results, but this does not have to hold true for third-party extensions as it is implementation specific.

Only the memory consumption directly attributed to the object is accounted for, not the memory consumption of objects it refers to.

If given, *default* will be returned if the object does not provide means to retrieve the size. Otherwise a `TypeError` will be raised.

`getsizeof()` calls the object’s `__sizeof__` method and adds an additional garbage collector overhead if the object is managed by the garbage collector.

See [recursive sizeof recipe](https://code.activestate.com/recipes/577504/) [https://code.activestate.com/recipes/577504/] for an example of using `getsizeof()` recursively to find the size of containers and all their

contents.

`sys.getswitchinterval()`

Return the interpreter's "thread switch interval"; see [setswitchinterval\(\)](#).

*New in version 3.2.*

`sys.getframe([depth])`

Return a frame object from the call stack. If optional integer *depth* is given, return the frame object that many calls below the top of the stack. If that is deeper than the call stack, [ValueError](#) is raised. The default for *depth* is zero, returning the frame at the top of the call stack.

Raises an [auditing event](#) `sys._getframe` with argument `frame`.

**CPython implementation detail:** This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

`sys.getframemodulename([depth])`

Return the name of a module from the call stack. If optional integer *depth* is given, return the module that many calls below the top of the stack. If that is deeper than the call stack, or if the module is unidentifiable, `None` is returned. The default for *depth* is zero, returning the module at the top of the call stack.

Raises an [auditing event](#) `sys._getframemodulename` with argument `depth`.

**CPython implementation detail:** This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

`sys.getprofile()`

Get the profiler function as set by `setprofile()`.

`sys.gettrace()`

Get the trace function as set by `settrace()`.

**CPython implementation detail:** The `gettrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

`sys.getwindowsversion()`

Return a named tuple describing the Windows version currently running. The named elements are *major*, *minor*, *build*, *platform*, *service\_pack*, *service\_pack\_minor*, *service\_pack\_major*, *suite\_mask*, *product\_type* and *platform\_version*. *service\_pack* contains a string, *platform\_version* a 3-tuple and all other values are integers. The components can also be accessed by name, so `sys.getwindowsversion()[0]` is equivalent to `sys.getwindowsversion().major`. For compatibility with prior versions, only the first 5 elements are retrievable by indexing.

*platform* will be 2 (`VER_PLATFORM_WIN32_NT`).

*product\_type* may be one of the following values:

#### **Meaning**

---

`VER_PLATFORM_WIN32_NT`

---

`VER_PLATFORM_WIN32_NT`

---

`VER_PLATFORM_WIN32_NT`, but not a domain controller.

---

This function wraps the Win32 `GetVersionEx()` function; see the Microsoft documentation on `OSVERSIONINFOEX()` for more information about these fields.

*platform\_version* returns the major version, minor version and build number of the current operating system, rather than the

version that is being emulated for the process. It is intended for use in logging rather than for feature detection.

### Note

*platform\_version* derives the version from kernel32.dll which can be of a different version than the OS version. Please use **platform** module for achieving accurate OS version.

**Availability:** Windows.

*Changed in version 3.2:* Changed to a named tuple and added *service\_pack\_minor*, *service\_pack\_major*, *suite\_mask*, and *product\_type*.

*Changed in version 3.6:* Added *platform\_version*

`sys.get_asyncgen_hooks()`

Returns an *asyncgen\_hooks* object, which is similar to a **namedtuple** of the form `(firstiter, finalizer)`, where *firstiter* and *finalizer* are expected to be either `None` or functions which take an **asynchronous generator iterator** as an argument, and are used to schedule finalization of an asynchronous generator by an event loop.

*New in version 3.6:* See **PEP 525** [<https://peps.python.org/pep-0525/>] for more details.

### Note

This function has been added on a provisional basis (see **PEP 411** [<https://peps.python.org/pep-0411/>] for details.)

`sys.get_coroutine_origin_tracking_depth()`

Get the current coroutine origin tracking depth, as set by **set\_coroutine\_origin\_tracking\_depth()**.

*New in version 3.7.*

### **Note**

This function has been added on a provisional basis (see [PEP 411](https://peps.python.org/pep-0411/) [https://peps.python.org/pep-0411/] for details.) Use it only for debugging purposes.

`sys.hash_info`

A [named tuple](#) giving parameters of the numeric hash implementation. For more details about hashing of numeric types, see [Hashing of numeric types](#).

`hash_info.width`

The width in bits used for hash values

`hash_info.modulus`

The prime modulus P used for numeric hash scheme

`hash_info.inf`

The hash value returned for a positive infinity

`hash_info.nan`

(This attribute is no longer used)

`hash_info.imag`

The multiplier used for the imaginary part of a complex number

`hash_info.algorithm`

The name of the algorithm for hashing of str, bytes, and memoryview

`hash_info.hash_bits`

The internal output size of the hash algorithm

`hash_info.seed_bits`

The size of the seed key of the hash algorithm

*New in version 3.2.*

*Changed in version 3.4:* Added `algorithm`, `hash_bits` and `seed_bits`

`sys.hexversion`

The version number encoded as a single integer. This is guaranteed to increase with each version, including proper support for non-production releases. For example, to test that the Python interpreter is at least version 1.5.2, use:

```
if sys.hexversion >= 0x010502F0:
    # use some advanced feature
    ...
else:
    # use an alternative implementation or warn the
    ...
```

This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in `hex()` function. The [named tuple](#) `sys.version_info` may be used for a more human-friendly encoding of the same information.

More details of `hexversion` can be found at [API and ABI Versioning](#).

`sys.implementation`

An object containing information about the implementation of the currently running Python interpreter. The following attributes are required to exist in all Python implementations.

*name* is the implementation's identifier, e.g. `'cpython'`. The actual string is defined by the Python implementation, but it is guaranteed to be lower case.

*version* is a named tuple, in the same format as `sys.version_info`. It represents the version of the Python

*implementation*. This has a distinct meaning from the specific version of the Python *language* to which the currently running interpreter conforms, which `sys.version_info` represents. For example, for PyPy 1.8 `sys.implementation.version` might be `sys.version_info(1, 8, 0, 'final', 0)`, whereas `sys.version_info` would be `sys.version_info(2, 7, 2, 'final', 0)`. For CPython they are the same value, since it is the reference implementation.

*hexversion* is the implementation version in hexadecimal format, like `sys.hexversion`.

*cache\_tag* is the tag used by the import machinery in the filenames of cached modules. By convention, it would be a composite of the implementation's name and version, like `'cpython-33'`. However, a Python implementation may use some other value if appropriate. If *cache\_tag* is set to `None`, it indicates that module caching should be disabled.

`sys.implementation` may contain additional attributes specific to the Python implementation. These non-standard attributes must start with an underscore, and are not described here. Regardless of its contents, `sys.implementation` will not change during a run of the interpreter, nor between implementation versions. (It may change between Python language versions, however.) See [PEP 421](https://peps.python.org/pep-0421/) [https://peps.python.org/pep-0421/] for more information.

*New in version 3.3.*

## Note

The addition of new required attributes must go through the normal PEP process. See [PEP 421](https://peps.python.org/pep-0421/) [https://peps.python.org/pep-0421/] for more information.

`sys.int_info`

A [named tuple](#) that holds information about Python's internal

representation of integers. The attributes are read only.

`int_info.bits_per_digit`

The number of bits held in each digit. Python integers are stored internally in base

`2**int_info.bits_per_digit`.

`int_info.sizeof_digit`

The size in bytes of the C type used to represent a digit.

`int_info.default_max_str_digits`

The default value for

`sys.get_int_max_str_digits()` when it is not otherwise explicitly configured.

`int_info.str_digits_check_threshold`

The minimum non-zero value for

`sys.set_int_max_str_digits()`,  
`PYTHONINTMAXSTRDIGITS`, or `-X`  
`int_max_str_digits`.

*New in version 3.1.*

*Changed in version 3.11:* Added `default_max_str_digits` and `str_digits_check_threshold`.

`sys._interactivehook_`

When this attribute exists, its value is automatically called (with no arguments) when the interpreter is launched in [interactive mode](#). This is done after the `PYTHONSTARTUP` file is read, so that you can set this hook there. The `site` module [sets this](#).

Raises an [auditing event](#) `cpython.run_interactivehook` with the hook object as the argument when the hook is called on startup.

*New in version 3.4.*

`sys.intern(string)`

Enter *string* in the table of “interned” strings and return the interned string – which is *string* itself or a copy. Interning strings is useful to gain a little performance on dictionary lookup – if the keys in a dictionary are interned, and the lookup key is interned, the key comparisons (after hashing) can be done by a pointer compare instead of a string compare. Normally, the names used in Python programs are automatically interned, and the dictionaries used to hold module, class or instance attributes have interned keys.

Interned strings are not immortal; you must keep a reference to the return value of `intern()` around to benefit from it.

`sys.is_finalizing()`

Return **True** if the Python interpreter is *shutting down*, **False** otherwise.

*New in version 3.5.*

`sys.last_exc`

This variable is not always defined; it is set to the exception instance when an exception is not handled and the interpreter prints an error message and a stack traceback. Its intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is `import pdb; pdb.pm()` to enter the post-mortem debugger; see `pdb` module for more information.)

*New in version 3.12.*

`sys.last_type`

`sys.last_value`

`sys.last_traceback`

These three variables are deprecated; use `sys.last_exc` instead. They hold the legacy representation of `sys.last_exc`, as returned from `exc_info()` above.

`sys.maxsize`

An integer giving the maximum value a variable of type `Py_ssize_t` can take. It's usually  $2^{31} - 1$  on a 32-bit platform and  $2^{63} - 1$  on a 64-bit platform.

`sys.maxunicode`

An integer giving the value of the largest Unicode code point, i.e. 1114111 (0x10FFFF in hexadecimal).

*Changed in version 3.3:* Before [PEP 393](https://peps.python.org/pep-0393/) [https://peps.python.org/pep-0393/], `sys.maxunicode` used to be either 0xFFFF or 0x10FFFF, depending on the configuration option that specified whether Unicode characters were stored as UCS-2 or UCS-4.

`sys.meta_path`

A list of [meta path finder](#) objects that have their `find_spec()` methods called to see if one of the objects can find the module to be imported. By default, it holds entries that implement Python's default import semantics. The `find_spec()` method is called with at least the absolute name of the module being imported. If the module to be imported is contained in a package, then the parent package's `__path__` attribute is passed in as a second argument. The method returns a [module spec](#), or `None` if the module cannot be found.

**See also**

[`importlib.abc.MetaPathFinder`](#)

The abstract base class defining the interface of finder objects on [meta\\_path](#).

[`importlib.machinery.ModuleSpec`](#)

The concrete class which `find_spec()` should return instances of.

*Changed in version 3.4:* [Module specs](#) were introduced in Python 3.4, by [PEP 451](https://peps.python.org/pep-0451/) [https://peps.python.org/pep-0451/].

Earlier versions of Python looked for a method called `find_module()`. This is still called as a fallback if a `meta_path` entry doesn't have a `find_spec()` method.

## `sys.modules`

This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. However, replacing the dictionary will not necessarily work as expected and deleting essential items from the dictionary may cause Python to fail. If you want to iterate over this global dictionary always use `sys.modules.copy()` or `tuple(sys.modules)` to avoid exceptions as its size may change during iteration as a side effect of code or activity in other threads.

## `sys.orig_argv`

The list of the original command line arguments passed to the Python executable.

See also `sys.argv`.

*New in version 3.10.*

## `sys.path`

A list of strings that specifies the search path for modules. Initialized from the environment variable `PYTHONPATH`, plus an installation-dependent default.

By default, as initialized upon program startup, a potentially unsafe path is prepended to `sys.path` (before the entries inserted as a result of `PYTHONPATH`):

- `python -m module` command line: prepend the current working directory.
- `python script.py` command line: prepend the script's directory. If it's a symbolic link, resolve symbolic links.
- `python -c code` and `python (REPL)` command lines: prepend an empty string, which means the

current working directory.

To not prepend this potentially unsafe path, use the `-P` command line option or the `PYTHONSAFEPATH` environment variable.

A program is free to modify this list for its own purposes. Only strings should be added to `sys.path`; all other data types are ignored during import.

### See also

- Module `site` This describes how to use `.pth` files to extend `sys.path`.

### `sys.path_hooks`

A list of callables that take a path argument to try to create a `finder` for the path. If a finder can be created, it is to be returned by the callable, else raise `ImportError`.

Originally specified in [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/].

### `sys.path_importer_cache`

A dictionary acting as a cache for `finder` objects. The keys are paths that have been passed to `sys.path_hooks` and the values are the finders that are found. If a path is a valid file system path but no finder is found on `sys.path_hooks` then `None` is stored.

Originally specified in [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/].

### `sys.platform`

This string contains a platform identifier that can be used to append platform-specific components to `sys.path`, for instance.

For Unix systems, except on Linux and AIX, this is the lowercased OS name as returned by `uname -s` with the first part of the version as returned by `uname -r` appended, e.g. 'sunos5' or 'freebsd8', *at the time when Python was built*. Unless you want to test for a specific system version, it is therefore recommended to use the following idiom:

```
if sys.platform.startswith('freebsd'):
    # FreeBSD-specific code here...
elif sys.platform.startswith('linux'):
    # Linux-specific code here...
elif sys.platform.startswith('aix'):
    # AIX-specific code here...
```

For other systems, the values are:

System	Platform value
AIX	'aix'
Emscripten	'emscripten'
Linux	'linux'
WSL	'wsl'
Windows	'win32'
Windows/Cygwin	'cygwin'
macOS	'darwin'

*Changed in version 3.3:* On Linux, `sys.platform` doesn't contain the major version anymore. It is always 'linux', instead of 'linux2' or 'linux3'. Since older Python versions include the version number, it is recommended to always use the `startswith` idiom presented above.

*Changed in version 3.8:* On AIX, `sys.platform` doesn't contain the major version anymore. It is always 'aix', instead of 'aix5' or 'aix7'. Since older Python versions include the version number, it is recommended to always use the `startswith` idiom presented above.

## See also

`os.name` has a coarser granularity. `os.uname()` gives system-dependent version information.

The **platform** module provides detailed checks for the system's identity.

### `sys.platlibdir`

Name of the platform-specific library directory. It is used to build the path of standard library and the paths of installed extension modules.

It is equal to `"lib"` on most platforms. On Fedora and SuSE, it is equal to `"lib64"` on 64-bit platforms which gives the following `sys.path` paths (where `X.Y` is the Python `major.minor` version):

- `/usr/lib64/pythonX.Y/`: Standard library (like `os.py` of the **os** module)
- `/usr/lib64/pythonX.Y/lib-dynload/`: C extension modules of the standard library (like the **errno** module, the exact filename is platform specific)
- `/usr/lib/pythonX.Y/site-packages/` (always use `lib`, not **sys.platlibdir**): Third-party modules
- `/usr/lib64/pythonX.Y/site-packages/`: C extension modules of third-party packages

*New in version 3.9.*

### `sys.prefix`

A string giving the site-specific directory prefix where the platform independent Python files are installed; on Unix, the default is `/usr/local`. This can be set at build time with the **--prefix** argument to the **configure** script. See [Installation paths](#) for derived paths.

### Note

If a **virtual environment** is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via **base\_prefix**.

`sys.ps1`

`sys.ps2`

Strings specifying the primary and secondary prompt of the interpreter. These are only defined if the interpreter is in interactive mode. Their initial values in this case are `'>>> '` and `'... '`. If a non-string object is assigned to either variable, its `str()` is re-evaluated each time the interpreter prepares to read a new interactive command; this can be used to implement a dynamic prompt.

`sys.setdlopenflags(n)`

Set the flags used by the interpreter for `dlopen()` calls, such as when the interpreter loads extension modules. Among other things, this will enable a lazy resolving of symbols when importing a module, if called as

`sys.setdlopenflags(0)`. To share symbols across extension modules, call as

`sys.setdlopenflags(os.RTLD_GLOBAL)`. Symbolic names for the flag values can be found in the `os` module (`RTLD_XXX` constants, e.g. `os.RTLD_LAZY`).

**Availability:** Unix.

`sys.set_int_max_str_digits(maxdigits)`

Set the [integer string conversion length limitation](#) used by this interpreter. See also `get_int_max_str_digits()`.

*New in version 3.11.*

`sys.setprofile(profilefunc)`

Set the system's profile function, which allows you to implement a Python source code profiler in Python. See chapter [The Python Profilers](#) for more information on the Python profiler. The system's profile function is called similarly to the system's trace function (see `settrace()`), but it is called with different events, for example it isn't called for each executed line of code (only on call and return, but

the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return `None`. Error in the profile function will cause itself unset.

Profile functions should have three arguments: *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string: 'call', 'return', 'c\_call', 'c\_return', or 'c\_exception'. *arg* depends on the event type.

Raises an [auditing event](#) `sys.setprofile` with no arguments.

The events have the following meaning:

'call'

A function is called (or some other code block entered). The profile function is called; *arg* is `None`.

'return'

A function (or other code block) is about to return. The profile function is called; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised.

'c\_call'

A C function is about to be called. This may be an extension function or a built-in. *arg* is the C function object.

'c\_return'

A C function has returned. *arg* is the C function object.

'c\_exception'

A C function has raised an exception. *arg* is the C function object.

`sys.setrecursionlimit(limit)`

Set the maximum depth of the Python interpreter stack to *limit*. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python.

The highest possible limit is platform-dependent. A user may need to set the limit higher when they have a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a too-high limit can lead to a crash.

If the new limit is too low at the current recursion depth, a `RecursionError` exception is raised.

*Changed in version 3.5.1:* A `RecursionError` exception is now raised if the new limit is too low at the current recursion depth.

`sys.setswitchinterval(interval)`

Set the interpreter's thread switch interval (in seconds). This floating-point value determines the ideal duration of the "timeslices" allocated to concurrently running Python threads. Please note that the actual value can be higher, especially if long-running internal functions or methods are used. Also, which thread becomes scheduled at the end of the interval is the operating system's decision. The interpreter doesn't have its own scheduler.

*New in version 3.2.*

`sys.settrace(tracefunc)`

Set the system's trace function, which allows you to implement a Python source code debugger in Python. The function is thread-specific; for a debugger to support multiple threads, it must register a trace function using `settrace()` for each thread being debugged or use `threading.settrace()`.

Trace functions should have three arguments: *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string: 'call', 'line', 'return', 'exception' or

'opcode'. *arg* depends on the event type.

The trace function is invoked (with *event* set to 'call') whenever a new local scope is entered; it should return a reference to a local trace function to be used for the new scope, or `None` if the scope shouldn't be traced.

The local trace function should return a reference to itself (or to another function for further tracing in that scope), or `None` to turn off tracing in that scope.

If there is any error occurred in the trace function, it will be unset, just like `settrace(None)` is called.

The events have the following meaning:

'call'

A function is called (or some other code block entered). The global trace function is called; *arg* is `None`; the return value specifies the local trace function.

'line'

The interpreter is about to execute a new line of code or re-execute the condition of a loop. The local trace function is called; *arg* is `None`; the return value specifies the new local trace function. See `Objects/lnotab_notes.txt` for a detailed explanation of how this works. Per-line events may be disabled for a frame by setting `f_trace_lines` to `False` on that [frame](#).

'return'

A function (or other code block) is about to return. The local trace function is called; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised. The trace function's return value is ignored.

'exception'

An exception has occurred. The local trace function is called; *arg* is a tuple (`exception`, `value`, `traceback`); the return value specifies the new local

trace function.

'opcode'

The interpreter is about to execute a new opcode (see [dis](#) for opcode details). The local trace function is called; *arg* is `None`; the return value specifies the new local trace function. Per-opcode events are not emitted by default: they must be explicitly requested by setting **f\_trace\_opcodes** to `True` on the [frame](#).

Note that as an exception is propagated down the chain of callers, an 'exception' event is generated at each level.

For more fine-grained usage, it's possible to set a trace function by assigning `frame.f_trace = tracefunc` explicitly, rather than relying on it being set indirectly via the return value from an already installed trace function. This is also required for activating the trace function on the current frame, which [settrace\(\)](#) doesn't do. Note that in order for this to work, a global tracing function must have been installed with [settrace\(\)](#) in order to enable the runtime tracing machinery, but it doesn't need to be the same tracing function (e.g. it could be a low overhead tracing function that simply returns `None` to disable itself immediately on each frame).

For more information on code and frame objects, refer to [The standard type hierarchy](#).

Raises an [auditing event](#) `sys.settrace` with no arguments.

**CPython implementation detail:** The [settrace\(\)](#) function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

*Changed in version 3.7:* 'opcode' event type added; **f\_trace\_lines** and **f\_trace\_opcodes** attributes added to frames

`sys.set_asyncgen_hooks(firstiter, finalizer)`

Accepts two optional keyword arguments which are callables that accept an [asynchronous generator iterator](#) as an argument. The *firstiter* callable will be called when an asynchronous generator is iterated for the first time. The *finalizer* will be called when an asynchronous generator is about to be garbage collected.

Raises an [auditing event](#)

`sys.set_asyncgen_hooks_firstiter` with no arguments.

Raises an [auditing event](#)

`sys.set_asyncgen_hooks_finalizer` with no arguments.

Two auditing events are raised because the underlying API consists of two calls, each of which must raise its own event.

*New in version 3.6:* See [PEP 525](#) [<https://peps.python.org/pep-0525/>] for more details, and for a reference example of a *finalizer* method see the implementation of `asyncio.Loop.shutdown_asyncgens` in [Lib/asyncio/base\\_events.py](#) [[https://github.com/python/cpython/tree/3.12/Lib/asyncio/base\\_events.py](https://github.com/python/cpython/tree/3.12/Lib/asyncio/base_events.py)]

### Note

This function has been added on a provisional basis (see [PEP 411](#) [<https://peps.python.org/pep-0411/>] for details.)

`sys.set_coroutine_origin_tracking_depth(depth)`

Allows enabling or disabling coroutine origin tracking. When enabled, the `cr_origin` attribute on coroutine objects will contain a tuple of (filename, line number, function name) tuples describing the traceback where the coroutine object was created, with the most recent call first. When disabled, `cr_origin` will be `None`.

To enable, pass a *depth* value greater than zero; this sets the number of frames whose information will be captured. To disable, pass set *depth* to zero.

This setting is thread-specific.

*New in version 3.7.*

### Note

This function has been added on a provisional basis (see [PEP 411](https://peps.python.org/pep-0411/) [https://peps.python.org/pep-0411/] for details.) Use it only for debugging purposes.

`sys.activate_stack_trampoline(backend, /)`

Activate the stack profiler trampoline *backend*. The only supported backend is "perf".

[Availability](#): Linux.

*New in version 3.12.*

### See also

- [Python support for the Linux perf profiler](#)
- <https://perf.wiki.kernel.org>

`sys.deactivate_stack_trampoline()`

Deactivate the current stack profiler trampoline backend.

If no stack profiler is activated, this function has no effect.

[Availability](#): Linux.

*New in version 3.12.*

`sys.is_stack_trampoline_active()`

Return `True` if a stack profiler trampoline is active.

**Availability:** Linux.

*New in version 3.12.*

`sys.enablelegacywindowsfsencoding()`

Changes the [filesystem encoding and error handler](#) to ‘mbcs’ and ‘replace’ respectively, for consistency with versions of Python prior to 3.6.

This is equivalent to defining the `PYTHONLEGACYWINDOWSFSENCODING` environment variable before launching Python.

See also `sys.getfilesystemencoding()` and `sys.getfilesystemencodeerrors()`.

**Availability:** Windows.

*New in version 3.6:* See [PEP 529](#) [<https://peps.python.org/pep-0529/>] for more details.

`sys.stdin`

`sys.stdout`

`sys.stderr`

[File objects](#) used by the interpreter for standard input, output and errors:

- `stdin` is used for all interactive input (including calls to `input()`);
- `stdout` is used for the output of `print()` and [expression](#) statements and for the prompts of `input()`;
- The interpreter’s own prompts and its error messages go to `stderr`.

These streams are regular [text files](#) like those returned by the `open()` function. Their parameters are chosen as follows:

- The encoding and error handling are initialized from

`PyConfig.stdio_encoding` and  
`PyConfig.stdio_errors`.

On Windows, UTF-8 is used for the console device. Non-character devices such as disk files and pipes use the system locale encoding (i.e. the ANSI codepage). Non-console character devices such as NUL (i.e. where `isatty()` returns `True`) use the value of the console input and output codepages at startup, respectively for `stdin` and `stdout/stderr`. This defaults to the system [locale encoding](#) if the process is not initially attached to a console.

The special behaviour of the console can be overridden by setting the environment variable `PYTHONLEGACYWINDOWSSTDIO` before starting Python. In that case, the console codepages are used as for any other character device.

Under all platforms, you can override the character encoding by setting the [PYTHONIOENCODING](#) environment variable before starting Python or by using the new `-X utf8` command line option and [PYTHONUTF8](#) environment variable. However, for the Windows console, this only applies when [PYTHONLEGACYWINDOWSSTDIO](#) is also set.

- When interactive, the `stdout` stream is line-buffered. Otherwise, it is block-buffered like regular text files. The `stderr` stream is line-buffered in both cases. You can make both streams unbuffered by passing the `-u` command-line option or setting the [PYTHONUNBUFFERED](#) environment variable.

*Changed in version 3.9:* Non-interactive `stderr` is now line-buffered instead of fully buffered.

## Note

To write or read binary data from/to the standard streams, use the underlying binary [buffer](#) object. For example, to

write bytes to `stdout`, use  
`sys.stdout.buffer.write(b'abc')`.

However, if you are writing a library (and do not control in which context its code will be executed), be aware that the standard streams may be replaced with file-like objects like `io.StringIO` which do not support the `:attr:buffer`` attribute.

`sys.__stdin__`  
`sys.__stdout__`  
`sys.__stderr__`

These objects contain the original values of `stdin`, `stderr` and `stdout` at the start of the program. They are used during finalization, and could be useful to print to the actual standard stream no matter if the `sys.std*` object has been redirected.

It can also be used to restore the actual files to known working file objects in case they have been overwritten with a broken object. However, the preferred way to do this is to explicitly save the previous stream before replacing it, and restore the saved object.

### Note

Under some conditions `stdin`, `stdout` and `stderr` as well as the original values `__stdin__`, `__stdout__` and `__stderr__` can be `None`. It is usually the case for Windows GUI apps that aren't connected to a console and Python apps started with **pythonw**.

`sys.stdlib_module_names`

A frozenset of strings containing the names of standard library modules.

It is the same on all platforms. Modules which are not

available on some platforms and modules disabled at Python build are also listed. All module kinds are listed: pure Python, built-in, frozen and extension modules. Test modules are excluded.

For packages, only the main package is listed: sub-packages and sub-modules are not listed. For example, the `email` package is listed, but the `email.mime` sub-package and the `email.message` sub-module are not listed.

See also the `sys.builtin_module_names` list.

*New in version 3.10.*

## `sys.thread_info`

A [named tuple](#) holding information about the thread implementation.

### `thread_info.name`

The name of the thread implementation:

- `"nt"`: Windows threads
- `"pthread"`: POSIX threads
- `"pthread-stubs"`: stub POSIX threads (on WebAssembly platforms without threading support)
- `"solaris"`: Solaris threads

### `thread_info.lock`

The name of the lock implementation:

- `"semaphore"`: a lock uses a semaphore
- `"mutex+cond"`: a lock uses a mutex and a condition variable
- `None` if this information is unknown

### `thread_info.version`

The name and version of the thread library. It is a string, or `None` if this information is unknown.

*New in version 3.3.*

## `sys.tracebacklimit`

When this variable is set to an integer value, it determines the maximum number of levels of traceback information printed when an unhandled exception occurs. The default is `1000`. When set to `0` or less, all traceback information is suppressed and only the exception type and value are printed.

## `sys.unraisablehook(unraisable, /)`

Handle an unraisable exception.

Called when an exception has occurred but there is no way for Python to handle it. For example, when a destructor raises an exception or during garbage collection (`gc.collect()`).

The *unraisable* argument has the following attributes:

- **exc\_type**: Exception type.
- **exc\_value**: Exception value, can be `None`.
- **exc\_traceback**: Exception traceback, can be `None`.
- **err\_msg**: Error message, can be `None`.
- **object**: Object causing the exception, can be `None`.

The default hook formats **err\_msg** and **object** as:

```
f'{err_msg}: {object!r}'; use "Exception ignored in"
error message if err_msg is None.
```

`sys.unraisablehook()` can be overridden to control how unraisable exceptions are handled.

## See also

`excepthook()` which handles uncaught exceptions.

## Warning

Storing **exc\_value** using a custom hook can create a reference cycle. It should be cleared explicitly to break the reference cycle when the exception is no longer needed.

Storing **object** using a custom hook can resurrect it if it is set to an object which is being finalized. Avoid storing **object** after the custom hook completes to avoid resurrecting objects.

Raise an auditing event `sys.unraisablehook` with arguments *hook*, *unraisable* when an exception that cannot be handled occurs. The *unraisable* object is the same as what will be passed to the hook. If no hook has been set, *hook* may be `None`.

*New in version 3.8.*

## `sys.version`

A string containing the version number of the Python interpreter plus additional information on the build number and compiler used. This string is displayed when the interactive interpreter is started. Do not extract version information out of it, rather, use `version_info` and the functions provided by the `platform` module.

## `sys.api_version`

The C API version for this interpreter. Programmers may find this useful when debugging version conflicts between Python and extension modules.

## `sys.version_info`

A tuple containing the five components of the version number: *major*, *minor*, *micro*, *releaselevel*, and *serial*. All values except *releaselevel* are integers; the release level is `'alpha'`, `'beta'`, `'candidate'`, or `'final'`. The `version_info` value corresponding to the Python version 2.0 is `(2, 0, 0, 'final', 0)`. The components can also be accessed by name, so `sys.version_info[0]` is equivalent to `sys.version_info.major` and so on.

*Changed in version 3.1:* Added named component attributes.

## `sys.warnoptions`

This is an implementation detail of the warnings framework; do not modify this value. Refer to the [warnings](#) module for more information on the warnings framework.

### `sys.winver`

The version number used to form registry keys on Windows platforms. This is stored as string resource 1000 in the Python DLL. The value is normally the major and minor versions of the running Python interpreter. It is provided in the [sys](#) module for informational purposes; modifying this value has no effect on the registry keys used by Python.

[Availability](#): Windows.

### `sys.monitoring`

Namespace containing functions and constants for register callbacks and controlling monitoring events. See [sys.monitoring](#) for details.

### `sys._xoptions`

A dictionary of the various implementation-specific flags passed through the [-X](#) command-line option. Option names are either mapped to their values, if given explicitly, or to [True](#). Example:

```
$ ./python -Xa=b -Xc
Python 3.2a3+ (py3k, Oct 16 2010, 20:14:50)
[GCC 4.4.3] on linux2
Type "help", "copyright", "credits" or "license" fo
>>> import sys
>>> sys._xoptions
{'a': 'b', 'c': True}
```

**CPython implementation detail:** This is a CPython-specific way of accessing options passed through [-X](#). Other implementations may export them through other means, or not at all.

*New in version 3.2.*

# `sys.monitoring` — Execution event monitoring

---

## Note

`sys.monitoring` is a namespace within the `sys` module, not an independent module, so there is no need to `import sys.monitoring`, simply `import sys` and then use `sys.monitoring`.

This namespace provides access to the functions and constants necessary to activate and control event monitoring.

As programs execute, events occur that might be of interest to tools that monitor execution. The **`sys.monitoring`** namespace provides means to receive callbacks when events of interest occur.

The monitoring API consists of three components:

- Tool identifiers
- Events
- Callbacks

## Tool identifiers

A tool identifier is an integer and associated name. Tool identifiers are used to discourage tools from interfering with each other and to allow multiple tools to operate at the same time. Currently tools are completely independent and cannot be used to monitor each other. This restriction may be lifted in the future.

Before registering or activating events, a tool should choose an identifier. Identifiers are integers in the range 0 to 5.

## Registering and using tools

`sys.monitoring.use_tool_id(id: int, name: str) → None`

Must be called before `id` can be used. `id` must be in the range 0 to 5 inclusive. Raises a `ValueError` if `id` is in use.

`sys.monitoring.free_tool_id(id: int) → None`

Should be called once a tool no longer requires `id`.

`sys.monitoring.get_tool(id: int) → str | None`

Returns the name of the tool if `id` is in use, otherwise it returns `None`. `id` must be in the range 0 to 5 inclusive.

All IDs are treated the same by the VM with regard to events, but the following IDs are pre-defined to make co-operation of tools easier:

```
sys.monitoring.DEBUGGER_ID = 0
sys.monitoring.COVERAGE_ID = 1
sys.monitoring.PROFILER_ID = 2
sys.monitoring.OPTIMIZER_ID = 5
```

There is no obligation to set an ID, nor is there anything preventing a tool from using an ID even it is already in use. However, tools are encouraged to use a unique ID and respect other tools.

## Events

The following events are supported:

### BRANCH

A conditional branch is taken (or not).

### CALL

A call in Python code (event occurs before the call).

### C\_RAISE

Exception raised from any callable, except Python functions

(event occurs after the exit).

#### C\_RETURN

Return from any callable, except Python functions (event occurs after the return).

#### EXCEPTION\_HANDLED

An exception is handled.

#### INSTRUCTION

A VM instruction is about to be executed.

#### JUMP

An unconditional jump in the control flow graph is made.

#### LINE

An instruction is about to be executed that has a different line number from the preceding instruction.

#### PY\_RESUME

Resumption of a Python function (for generator and coroutine functions), except for throw() calls.

#### PY\_RETURN

Return from a Python function (occurs immediately before the return, the callee's frame will be on the stack).

#### PY\_START

Start of a Python function (occurs immediately after the call, the callee's frame will be on the stack)

#### PY\_THROW

A Python function is resumed by a throw() call.

#### PY\_UNWIND

Exit from a Python function during exception unwinding.

#### PY\_YIELD

Yield from a Python function (occurs immediately before the yield, the callee's frame will be on the stack).

#### RAISE

An exception is raised, except those that cause a `STOP_ITERATION` event.

#### **RERAISE**

An exception is re-raised, for example at the end of a `finally` block.

#### **STOP\_ITERATION**

An artificial `StopIteration` is raised; see [the `STOP\_ITERATION` event](#).

More events may be added in the future.

These events are attributes of the **`sys.monitoring.events`** namespace. Each event is represented as a power-of-2 integer constant. To define a set of events, simply bitwise or the individual events together. For example, to specify both `PY_RETURN` and `PY_START` events, use the expression `PY_RETURN | PY_START`.

Events are divided into three groups:

### **Local events**

Local events are associated with normal execution of the program and happen at clearly defined locations. All local events can be disabled. The local events are:

- `PY_START`
- `PY_RESUME`
- `PY_RETURN`
- `PY_YIELD`
- `CALL`
- `LINE`
- `INSTRUCTION`
- `JUMP`
- `BRANCH`
- `STOP_ITERATION`

### **Ancillary events**

Ancillary events can be monitored like other events, but are controlled by another event:

- `C_RAISE`
- `C_RETURN`

The `C_RETURN` and `C_RAISE` events are controlled by the `CALL` event. `C_RETURN` and `C_RAISE` events will only be seen if the corresponding `CALL` event is being monitored.

## Other events

Other events are not necessarily tied to a specific location in the program and cannot be individually disabled.

The other events that can be monitored are:

- `PY_THROW`
- `PY_UNWIND`
- `RAISE`
- `EXCEPTION_HANDLED`

## The `STOP_ITERATION` event

**PEP 380** [<https://peps.python.org/pep-0380/#use-of-stopiteration-to-return-values>] specifies that a `StopIteration` exception is raised when returning a value from a generator or coroutine. However, this is a very inefficient way to return a value, so some Python implementations, notably CPython 3.12+, do not raise an exception unless it would be visible to other code.

To allow tools to monitor for real exceptions without slowing down generators and coroutines, the `STOP_ITERATION` event is provided. `STOP_ITERATION` can be locally disabled, unlike `RAISE`.

## Turning events on and off

In order to monitor an event, it must be turned on and a callback registered. Events can be turned on or off by setting the events

either globally or for a particular code object.

## Setting events globally

Events can be controlled globally by modifying the set of events being monitored.

`sys.monitoring.get_events(tool_id: int) → int`

Returns the `int` representing all the active events.

`sys.monitoring.set_events(tool_id: int, event_set: int)`

Activates all events which are set in `event_set`. Raises a `ValueError` if `tool_id` is not in use.

No events are active by default.

## Per code object events

Events can also be controlled on a per code object basis.

`sys.monitoring.get_local_events(tool_id: int, code: CodeType) → int`

Returns all the local events for `code`

`sys.monitoring.set_local_events(tool_id: int, code: CodeType, event_set: int)`

Activates all the local events for `code` which are set in `event_set`. Raises a `ValueError` if `tool_id` is not in use.

Local events add to global events, but do not mask them. In other words, all global events will trigger for a code object, regardless of the local events.

## Disabling events

Local events can be disabled for a specific code location by returning `sys.monitoring.DISABLE` from a callback function.

This does not change which events are set, or any other code locations for the same event.

Disabling events for specific locations is very important for high performance monitoring. For example, a program can be run under a debugger with no overhead if the debugger disables all monitoring except for a few breakpoints.

## Registering callback functions

To register a callable for events call

```
sys.monitoring.register_callback(tool_id: int, event: int, func: Callable | None) → Callable | None
```

Registers the callable `func` for the `event` with the given `tool_id`

If another callback was registered for the given `tool_id` and `event`, it is unregistered and returned. Otherwise `register_callback` returns `None`.

Functions can be unregistered by calling

```
sys.monitoring.unregister_callback(tool_id, event, None).
```

Callback functions can be registered and unregistered at any time.

Registering or unregistering a callback function will generate a `sys.audit` event.

## Callback function arguments

When an active event occurs, the registered callback function is called. Different events will provide the callback function with different arguments, as follows:

- `PY_START` and `PY_RESUME`:

```
func(code: CodeType, instruction_offset: int) -> DI
```

- **PY\_RETURN and PY\_YIELD:**

```
func(code: CodeType,  
instruction_offset: int, retval:  
object) -> DISABLE | Any
```

- **CALL, C\_RAISE and C\_RETURN:**

```
func(code: CodeType,  
instruction_offset: int,  
callable: object, arg0: object |  
MISSING) -> DISABLE | Any
```

If there are no arguments, `arg0` is set to `MISSING`.

- **RAISE, RERAISE, EXCEPTION\_HANDLED, PY\_UNWIND, PY\_THROW and STOP\_ITERATION:**

```
func(code: CodeType,  
instruction_offset: int,  
exception: BaseException) ->  
DISABLE | Any
```

- **LINE:**

```
func(code: CodeType, line_number:  
int) -> DISABLE | Any
```

- **BRANCH and JUMP:**

```
func(code: CodeType,  
instruction_offset: int,  
destination_offset: int) ->  
DISABLE | Any
```

Note that the `destination_offset` is where the code will next execute. For an untaken branch this will be the offset of the instruction following the branch.

- **INSTRUCTION:**

```
func(code: CodeType,  
instruction_offset: int) ->  
DISABLE | Any
```

# `sysconfig` — Provide access to Python's configuration information

*New in version 3.2.*

**Source code:** [Lib/sysconfig.py](https://github.com/python/cpython/tree/3.12/Lib/sysconfig.py) [https://github.com/python/cpython/tree/3.12/Lib/sysconfig.py]

---

The `sysconfig` module provides access to Python's configuration information like the list of installation paths and the configuration variables relevant for the current platform.

## Configuration variables

A Python distribution contains a `Makefile` and a `pyconfig.h` header file that are necessary to build both the Python binary itself and third-party C extensions compiled using `setuptools`.

`sysconfig` puts all variables found in these files in a dictionary that can be accessed using `get_config_vars()` or `get_config_var()`.

Notice that on Windows, it's a much smaller set.

`sysconfig.get_config_vars(*args)`

With no arguments, return a dictionary of all configuration variables relevant for the current platform.

With arguments, return a list of values that result from looking up each argument in the configuration variable dictionary.

For each argument, if the value is not found, return `None`.

`sysconfig.get_config_var(name)`

Return the value of a single variable *name*. Equivalent to `get_config_vars().get(name)`.

If *name* is not found, return `None`.

Example of usage:

```
>>> import sysconfig
>>> sysconfig.get_config_var('Py_ENABLE_SHARED')
0
>>> sysconfig.get_config_var('LIBDIR')
'/usr/local/lib'
>>> sysconfig.get_config_vars('AR', 'CXX')
['ar', 'g++']
```

## Installation paths

Python uses an installation scheme that differs depending on the platform and on the installation options. These schemes are stored in `sysconfig` under unique identifiers based on the value returned by `os.name`. The schemes are used by package installers to determine where to copy files to.

Python currently supports nine schemes:

- *posix\_prefix*: scheme for POSIX platforms like Linux or macOS. This is the default scheme used when Python or a component is installed.
- *posix\_home*: scheme for POSIX platforms, when the *home* option is used. This scheme defines paths located under a specific home prefix.
- *posix\_user*: scheme for POSIX platforms, when the *user* option is used. This scheme defines paths located under the user's home directory (`site.USER_BASE`).
- *posix\_venv*: scheme for `Python virtual environments` on POSIX platforms; by default it is the same as *posix\_prefix*.

- *nt*: scheme for Windows. This is the default scheme used when Python or a component is installed.
- *nt\_user*: scheme for Windows, when the *user* option is used.
- *nt\_venv*: scheme for **Python virtual environments** on Windows; by default it is the same as *nt*.
- *venv*: a scheme with values from either *posix\_venv* or *nt\_venv* depending on the platform Python runs on.
- *osx\_framework\_user*: scheme for macOS, when the *user* option is used.

Each scheme is itself composed of a series of paths and each path has a unique identifier. Python currently uses eight paths:

- *stdlib*: directory containing the standard Python library files that are not platform-specific.
- *platstdlib*: directory containing the standard Python library files that are platform-specific.
- *platlib*: directory for site-specific, platform-specific files.
- *purelib*: directory for site-specific, non-platform-specific files ('pure' Python).
- *include*: directory for non-platform-specific header files for the Python C-API.
- *platinclude*: directory for platform-specific header files for the Python C-API.
- *scripts*: directory for script files.
- *data*: directory for data files.

## User scheme

This scheme is designed to be the most convenient solution for users that don't have write permission to the global site-packages directory or don't want to install into it.

Files will be installed into subdirectories of **site.USER\_BASE** (written as *userbase* hereafter). This scheme installs pure Python modules and extension modules in the same location (also known as **site.USER\_SITE**).

## Home scheme

The idea behind the “home scheme” is that you build and maintain a personal stash of Python modules. This scheme’s name is derived from the idea of a “home” directory on Unix, since it’s not unusual for a Unix user to make their home directory have a layout similar to /usr/ or /usr/local/. This scheme can be used by anyone, regardless of the operating system they are installing for.

## Prefix scheme

The “prefix scheme” is useful when you wish to use one Python installation to perform the build/install (i.e., to run the setup script), but install modules into the third-party module directory of a different Python installation (or something that looks like a different Python installation). If this sounds a trifle unusual, it is—that’s why the user and home schemes come before. However, there are at least two known cases where the prefix scheme will be useful.

First, consider that many Linux distributions put Python in `/usr`, rather than the more traditional `/usr/local`. This is entirely appropriate, since in those cases Python is part of “the system” rather than a local add-on. However, if you are installing Python modules from source, you probably want them to go in `/usr/local/lib/python2.X` rather than `/usr/lib/python2.X`.

Another possibility is a network filesystem where the name used to write to a remote directory is different from the name used to read it: for example, the Python interpreter accessed as `/usr/local/bin/python` might search for modules in `/usr/local/lib/python2.X`, but those modules would have to be installed to, say, `/mnt/@server/export/lib/python2.X`.

## Installation path functions

**sysconfig** provides some functions to determine these installation paths.

`sysconfig.get_scheme_names()`

Return a tuple containing all schemes currently supported in **sysconfig**.

`sysconfig.get_default_scheme()`

Return the default scheme name for the current platform.

*New in version 3.10:* This function was previously named `_get_default_scheme()` and considered an implementation detail.

*Changed in version 3.11:* When Python runs from a virtual environment, the `venv` scheme is returned.

`sysconfig.get_preferred_scheme(key)`

Return a preferred scheme name for an installation layout specified by *key*.

*key* must be either "prefix", "home", or "user".

The return value is a scheme name listed in `get_scheme_names()`. It can be passed to `sysconfig` functions that take a *scheme* argument, such as `get_paths()`.

*New in version 3.10.*

*Changed in version 3.11:* When Python runs from a virtual environment and `key="prefix"`, the *venv* scheme is returned.

`sysconfig.get_preferred_schemes()`

Return a dict containing preferred scheme names on the current platform. Python implementers and redistributors may add their preferred schemes to the `_INSTALL_SCHEMES` module-level global value, and modify this function to return those scheme names, to e.g. provide different schemes for system and language package managers to use, so packages installed by either do not mix with those by the other.

End users should not use this function, but `get_default_scheme()` and `get_preferred_scheme()` instead.

*New in version 3.10.*

`sysconfig.get_path_names()`

Return a tuple containing all path names currently supported in `sysconfig`.

`sysconfig.get_path(name[, scheme[, vars[, expand]]])`

Return an installation path corresponding to the path *name*, from the install scheme named *scheme*.

*name* has to be a value from the list returned by `get_path_names()`.

`sysconfig` stores installation paths corresponding to each path name, for each platform, with variables to be expanded. For instance the *stdlib* path for the *nt* scheme is: `{base}/Lib`.

`get_path()` will use the variables returned by `get_config_vars()` to expand the path. All variables have default values for each platform so one may call this function and get the default value.

If *scheme* is provided, it must be a value from the list returned by `get_scheme_names()`. Otherwise, the default scheme for the current platform is used.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary returned by `get_config_vars()`.

If *expand* is set to `False`, the path will not be expanded using the variables.

If *name* is not found, raise a `KeyError`.

`sysconfig.get_paths([scheme[, vars[, expand]]])`

Return a dictionary containing all installation paths corresponding to an installation scheme. See `get_path()` for more information.

If *scheme* is not provided, will use the default scheme for the current platform.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary used to expand the paths.

If *expand* is set to `false`, the paths will not be expanded.

If *scheme* is not an existing scheme, `get_paths()` will raise a `KeyError`.

# Other functions

`sysconfig.get_python_version()`

Return the MAJOR.MINOR Python version number as a string. Similar to `'%d.%d' % sys.version_info[:2]`.

`sysconfig.get_platform()`

Return a string that identifies the current platform.

This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by `os.uname()`), although the exact information included depends on the OS; e.g., on Linux, the kernel version isn't particularly important.

Examples of returned values:

- `linux-i586`
- `linux-alpha (?)`
- `solaris-2.6-sun4u`

Windows will return one of:

- `win-amd64` (64bit Windows on AMD64, aka x86\_64, Intel64, and EM64T)
- `win32` (all others - specifically, `sys.platform` is returned)

macOS can return:

- `macosx-10.6-ppc`
- `macosx-10.4-ppc64`
- `macosx-10.3-i386`
- `macosx-10.4-fat`

For other non-POSIX platforms, currently just returns `sys.platform`.

`sysconfig.is_python_build()`

Return `True` if the running Python interpreter was built from source and is being run from its built location, and not from a location resulting from e.g. running `make install` or installing via a binary installer.

`sysconfig.parse_config_h(fp[, vars])`

Parse a `config.h`-style file.

*fp* is a file-like object pointing to the `config.h`-like file.

A dictionary containing name/value pairs is returned. If an optional dictionary is passed in as the second argument, it is used instead of a new dictionary, and updated with the values read in the file.

`sysconfig.get_config_h_filename()`

Return the path of `pyconfig.h`.

`sysconfig.get_makefile_filename()`

Return the path of `Makefile`.

## Using **sysconfig** as a script

You can use **sysconfig** as a script with Python's `-m` option:

```
$ python -m sysconfig
```

```
Platform: "macosx-10.4-i386"
```

```
Python version: "3.2"
```

```
Current installation scheme: "posix_prefix"
```

Paths:

```
data = "/usr/local"
```

```
include = "/Users/tarek/Dev/svn.python.org/py3k/
```

```
platinclude = "."
```

```
platlib = "/usr/local/lib/python3.2/site-package
```

```
platstdlib = "/usr/local/lib/python3.2"
```

```
purelib = "/usr/local/lib/python3.2/site-package
```

```
scripts = "/usr/local/bin"  
stdlib = "/usr/local/lib/python3.2"
```

Variables:

```
AC_APPLE_UNIVERSAL_BUILD = "0"  
AIX_GENUINE_CPLUSPLUS = "0"  
AR = "ar"  
ARFLAGS = "rc"  
...
```

This call will print in the standard output the information returned by `get_platform()`, `get_python_version()`, `get_path()` and `get_config_vars()`.

# `builtins` — Built-in objects

---

This module provides direct access to all ‘built-in’ identifiers of Python; for example, `builtins.open` is the full name for the built-in function `open()`. See [Built-in Functions](#) and [Built-in Constants](#) for documentation.

This module is not normally accessed explicitly by most applications, but can be useful in modules that provide objects with the same name as a built-in value, but in which the built-in of that name is also needed. For example, in a module that wants to implement an `open()` function that wraps the built-in `open()`, this module can be used directly:

```
import builtins

def open(path):
    f = builtins.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''Wrapper around a file that converts output to upper case'''

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

    # ...
```

As an implementation detail, most modules have the name `__builtins__` made available as part of their globals. The value of `__builtins__` is normally either this module or the value of this module’s `__dict__` attribute. Since this is an implementation

detail, it may not be used by alternate implementations of Python.

# `__main__` — Top-level code environment

---

In Python, the special name `__main__` is used for two important constructs:

1. the name of the top-level environment of the program, which can be checked using the `__name__ == '__main__'` expression; and
2. the `__main__.py` file in Python packages.

Both of these mechanisms are related to Python modules; how users interact with them and how they interact with each other. They are explained in detail below. If you're new to Python modules, see the tutorial section [Modules](#) for an introduction.

## `__name__ == '__main__'`

When a Python module or package is imported, `__name__` is set to the module's name. Usually, this is the name of the Python file itself without the `.py` extension:

```
>>> import configparser
>>> configparser.__name__
'configparser'
```

If the file is part of a package, `__name__` will also include the parent package's path:

```
>>> from concurrent.futures import process
>>> process.__name__
'concurrent.futures.process'
```

However, if the module is executed in the top-level code

environment, its `__name__` is set to the string `'__main__'`.

## What is the “top-level code environment”?

`__main__` is the name of the environment where top-level code is run. “Top-level code” is the first user-specified Python module that starts running. It’s “top-level” because it imports all other modules that the program needs. Sometimes “top-level code” is called an *entry point* to the application.

The top-level code environment can be:

- the scope of an interactive prompt:

```
>>> __name__  
'__main__'
```

- the Python module passed to the Python interpreter as a file argument:

```
$ python helloworld.py  
Hello, world!
```

- the Python module or package passed to the Python interpreter with the `-m` argument:

```
$ python -m tarfile  
usage: tarfile.py [-h] [-v] (...)
```

- Python code read by the Python interpreter from standard input:

```
$ echo "import this" | python  
The Zen of Python, by Tim Peters
```

```
Beautiful is better than ugly.  
Explicit is better than implicit.  
...
```

- Python code passed to the Python interpreter with the `-c` argument:

```
$ python -c "import this"
The Zen of Python, by Tim Peters

Beautiful is better than ugly.
Explicit is better than implicit.
...
```

In each of these situations, the top-level module's `__name__` is set to `'__main__'`.

As a result, a module can discover whether or not it is running in the top-level environment by checking its own `__name__`, which allows a common idiom for conditionally executing code when the module is not initialized from an import statement:

```
if __name__ == '__main__':
    # Execute when the module is not initialized from an
    ...
```

### See also

For a more detailed look at how `__name__` is set in all situations, see the tutorial section [Modules](#).

## Idiomatic Usage

Some modules contain code that is intended for script use only, like parsing command-line arguments or fetching data from standard input. If a module like this was imported from a different module, for example to unit test it, the script code would unintentionally execute as well.

This is where using the `if __name__ == '__main__':` code block comes in handy. Code within this block won't run unless the module is executed in the top-level environment.

Putting as few statements as possible in the block below `if __name__ == '__main__':` can improve code clarity and correctness. Most often, a function named `main` encapsulates the program's primary behavior:

```
# echo.py

import shlex
import sys

def echo(phrase: str) -> None:
    """A dummy wrapper around print."""
    # for demonstration purposes, you can imagine that the
    # valuable and reusable logic inside this function
    print(phrase)

def main() -> int:
    """Echo the input arguments to standard output"""
    phrase = shlex.join(sys.argv)
    echo(phrase)
    return 0

if __name__ == '__main__':
    sys.exit(main()) # next section explains the use of
```

Note that if the module didn't encapsulate code inside the `main` function but instead put it directly within the `if __name__ == '__main__':` block, the `phrase` variable would be global to the entire module. This is error-prone as other functions within the module could be unintentionally using the global variable instead of a local name. A `main` function solves this problem.

Using a `main` function has the added benefit of the `echo` function itself being isolated and importable elsewhere. When `echo.py` is imported, the `echo` and `main` functions will be defined, but neither of them will be called, because `__name__ != '__main__'`.

## Packaging Considerations

`main` functions are often used to create command-line tools by specifying them as entry points for console scripts. When this is done, [pip](https://pip.pypa.io/) [https://pip.pypa.io/] inserts the function call into a template script, where the return value of `main` is passed into

`sys.exit()`. For example:

```
sys.exit(main())
```

Since the call to `main` is wrapped in `sys.exit()`, the expectation is that your function will return some value acceptable as an input to `sys.exit()`; typically, an integer or `None` (which is implicitly returned if your function does not have a return statement).

By proactively following this convention ourselves, our module will have the same behavior when run directly (i.e. `python echo.py`) as it will have if we later package it as a console script entry-point in a pip-installable package.

In particular, be careful about returning strings from your `main` function. `sys.exit()` will interpret a string argument as a failure message, so your program will have an exit code of `1`, indicating failure, and the string will be written to `sys.stderr`. The `echo.py` example from earlier exemplifies using the `sys.exit(main())` convention.

[Python Packaging User Guide](https://packaging.python.org/) [https://packaging.python.org/] contains a collection of tutorials and references on how to distribute and install Python packages with modern tools.

## `__main__.py` in Python Packages

If you are not familiar with Python packages, see section [Packages](#) of the tutorial. Most commonly, the `__main__.py` file is used to provide a command-line interface for a package. Consider the following hypothetical package, “bandclass”:

```
bandclass
  __init__.py
  __main__.py
  student.py
```

`__main__.py` will be executed when the package itself is invoked directly from the command line using the `-m` flag. For example:

```
$ python -m bandclass
```

This command will cause `__main__.py` to run. How you utilize this mechanism will depend on the nature of the package you are writing, but in this hypothetical case, it might make sense to allow the teacher to search for students:

```
# bandclass/__main__.py
```

```
import sys
```

```
from .student import search_students
```

```
student_name = sys.argv[2] if len(sys.argv) >= 2 else ''
print(f'Found student: {search_students(student_name)}')
```

Note that `from .student import search_students` is an example of a relative import. This import style can be used when referencing modules within a package. For more details, see [Intra-package References](#) in the [Modules](#) section of the tutorial.

## Idiomatic Usage

The content of `__main__.py` typically isn't fenced with an `if __name__ == '__main__':` block. Instead, those files are kept short and import functions to execute from other modules. Those other modules can then be easily unit-tested and are properly reusable.

If used, an `if __name__ == '__main__':` block will still work as expected for a `__main__.py` file within a package, because its `__name__` attribute will include the package's path if imported:

```
>>> import asyncio.__main__
>>> asyncio.__main__.__name__
'asyncio.__main__'
```

This won't work for `__main__.py` files in the root directory of a `.zip` file though. Hence, for consistency, minimal `__main__.py`

like the **venv** one mentioned below are preferred.

## See also

See **venv** for an example of a package with a minimal `__main__.py` in the standard library. It doesn't contain a `if __name__ == '__main__':` block. You can invoke it with `python -m venv [directory]`.

See **runpy** for more details on the `-m` flag to the interpreter executable.

See **zipapp** for how to run applications packaged as `.zip` files. In this case Python looks for a `__main__.py` file in the root directory of the archive.

## `import __main__`

Regardless of which module a Python program was started with, other modules running within that same program can import the top-level environment's scope (**namespace**) by importing the `__main__` module. This doesn't import a `__main__.py` file but rather whichever module that received the special name `'__main__'`.

Here is an example module that consumes the `__main__` namespace:

```
# namely.py
```

```
import __main__
```

```
def did_user_define_their_name():  
    return 'my_name' in dir(__main__)
```

```
def print_user_name():  
    if not did_user_define_their_name():  
        raise ValueError('Define the variable `my_name`!')
```

```
if '__file__' in dir(__main__):
    print(__main__.my_name, "found in file", __main__.__file__)
else:
    print(__main__.my_name)
```

Example usage of this module could be as follows:

```
# start.py

import sys

from namely import print_user_name

# my_name = "Dinsdale"

def main():
    try:
        print_user_name()
    except ValueError as ve:
        return str(ve)

if __name__ == "__main__":
    sys.exit(main())
```

Now, if we started our program, the result would look like this:

```
$ python start.py
Define the variable `my_name`!
```

The exit code of the program would be 1, indicating an error. Uncommenting the line with `my_name = "Dinsdale"` fixes the program and now it exits with status code 0, indicating success:

```
$ python start.py
Dinsdale found in file /path/to/start.py
```

Note that importing `__main__` doesn't cause any issues with unintentionally running top-level code meant for script use which is put in the `if __name__ == "__main__"` block of the `start` module. Why does this work?

Python inserts an empty `__main__` module in `sys.modules` at interpreter startup, and populates it by running top-level code. In our example this is the `start` module which runs line by line and imports `namely`. In turn, `namely` imports `__main__` (which is really `start`). That’s an import cycle! Fortunately, since the partially populated `__main__` module is present in `sys.modules`, Python passes that to `namely`. See [Special considerations for `\_\_main\_\_`](#) in the import system’s reference for details on how this works.

The Python REPL is another example of a “top-level environment”, so anything defined in the REPL becomes part of the `__main__` scope:

```
>>> import namely
>>> namely.did_user_define_their_name()
False
>>> namely.print_user_name()
Traceback (most recent call last):
...
ValueError: Define the variable `my_name`!
>>> my_name = 'Jabberwocky'
>>> namely.did_user_define_their_name()
True
>>> namely.print_user_name()
Jabberwocky
```

Note that in this case the `__main__` scope doesn’t contain a `__file__` attribute as it’s interactive.

The `__main__` scope is used in the implementation of `pdb` and `rlcompleter`.

# warnings — Warning control

**Source code:** [Lib/warnings.py](https://github.com/python/cpython/tree/3.12/Lib/warnings.py) [https://github.com/python/cpython/tree/3.12/Lib/warnings.py]

---

Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn't warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx()`; see [Exception Handling](#) for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the [warning category](#), the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control: first, each time a warning is issued, a determination is made whether a message should be issued or not; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the [warning filter](#), which is a sequence of matching rules and actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.

The printing of warning messages is done by calling `showwarning()`, which may be overridden; the default

implementation of this function formats the message by calling `formatwarning()`, which is also available for use by custom implementations.

See also

`logging.captureWarnings()` allows you to handle all warnings with the standard logging infrastructure.

## Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings.

While these are technically [built-in exceptions](#), they are documented here, because conceptually they belong to the warnings mechanism.

User code can define additional warning categories by subclassing one of the standard warning categories. A warning category must always be a subclass of the `Warning` class.

The following warnings category classes are currently defined:

Description
This is the base class of all warning category classes. It is a subclass of <code>Exception</code> .
The default category for <code>warn()</code> .
Base category for warnings about deprecated features when those warnings are intended for other Python developers (ignored by default, unless triggered by code in <code>__main__</code> ).
Base category for warnings about dubious syntactic features.
Base category for warnings about dubious runtime features.
Base category for warnings about deprecated features when those warnings are intended for end users of applications that are written in Python.
Base category for warnings about features that will be deprecated in the future (ignored by default).

**Base category for** warnings triggered during the process of importing a module (ignored by default).

---

**Base category for** warnings related to Unicode.

---

**Base category for** warnings related to **bytes** and **bytearray**.

---

**Base category for** warnings related to resource usage (ignored by default).

---

*Changed in version 3.7:* Previously **DeprecationWarning** and **FutureWarning** were distinguished based on whether a feature was being removed entirely or changing its behaviour. They are now distinguished based on their intended audience and the way they're handled by the default warnings filters.

## The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the filter determines the disposition of the match. Each entry is a tuple of the form (*action*, *message*, *category*, *module*, *lineno*), where:

- *action* is one of the following strings:

### **Disposition**

---

**print** the first occurrence of matching warnings for each location (module + line number) where the warning is issued

---

**turn** matching warnings into exceptions

---

**never print** matching warnings

---

**always print** matching warnings

---

**print** the first occurrence of matching warnings for each module where the warning is issued (regardless of line number)

---

**print only** the first occurrence of matching warnings, regardless of location

---

- *message* is a string containing a regular expression that the

start of the warning message must match, case-insensitively. In `-W` and `PYTHONWARNINGS`, *message* is a literal string that the start of the warning message must contain (case-insensitively), ignoring any whitespace at the start or end of *message*.

- *category* is a class (a subclass of `Warning`) of which the warning category must be a subclass in order to match.
- *module* is a string containing a regular expression that the start of the fully qualified module name must match, case-sensitively. In `-W` and `PYTHONWARNINGS`, *module* is a literal string that the fully qualified module name must be equal to (case-sensitively), ignoring any whitespace at the start or end of *module*.
- *lineno* is an integer that the line number where the warning occurred must match, or `0` to match all line numbers.

Since the `Warning` class is derived from the built-in `Exception` class, to turn a warning into an error we simply raise `category(message)`.

If a warning is reported and doesn't match any registered filter then the "default" action is applied (hence its name).

## Describing Warning Filters

The warnings filter is initialized by `-W` options passed to the Python interpreter command line and the `PYTHONWARNINGS` environment variable. The interpreter saves the arguments for all supplied entries without interpretation in `sys.warnoptions`; the `warnings` module parses these when it is first imported (invalid options are ignored, after printing a message to `sys.stderr`).

Individual warnings filters are specified as a sequence of fields separated by colons:

```
action:message:category:module:line
```

The meaning of each of these fields is as described in [The Warnings](#)

**Filter.** When listing multiple filters on a single line (as for **PYTHONWARNINGS**), the individual filters are separated by commas and the filters listed later take precedence over those listed before them (as they're applied left-to-right, and the most recently applied filters take precedence over earlier ones).

Commonly used warning filters apply to either all warnings, warnings in a particular category, or warnings raised by particular modules or packages. Some examples:

```
default                # Show all warnings (even t
ignore                 # Ignore all warnings
error                  # Convert all warnings to e
error::ResourceWarning # Treat ResourceWarning mes
default::DeprecationWarning # Show DeprecationWarning m
ignore,default::mymodule # Only report warnings trig
error::mymodule        # Convert warnings to error
```

## Default Warning Filter

By default, Python installs several warning filters, which can be overridden by the **-W** command-line option, the **PYTHONWARNINGS** environment variable and calls to **filterwarnings()**.

In regular release builds, the default warning filter has the following entries (in order of precedence):

```
default::DeprecationWarning:__main__
ignore::DeprecationWarning
ignore::PendingDeprecationWarning
ignore::ImportWarning
ignore::ResourceWarning
```

In a **debug build**, the list of default warning filters is empty.

*Changed in version 3.2:* **DeprecationWarning** is now ignored by default in addition to **PendingDeprecationWarning**.

*Changed in version 3.7:* **DeprecationWarning** is once again shown by default when triggered directly by code in **\_\_main\_\_**.

Changed in version 3.7: **BytesWarning** no longer appears in the default filter list and is instead configured via **sys.warnoptions** when **-b** is specified twice.

## Overriding the default filter

Developers of applications written in Python may wish to hide *all* Python level warnings from their users by default, and only display them when running tests or otherwise working on the application. The **sys.warnoptions** attribute used to pass filter configurations to the interpreter can be used as a marker to indicate whether or not warnings should be disabled:

```
import sys

if not sys.warnoptions:
    import warnings
    warnings.simplefilter("ignore")
```

Developers of test runners for Python code are advised to instead ensure that *all* warnings are displayed by default for the code under test, using code like:

```
import sys

if not sys.warnoptions:
    import os, warnings
    warnings.simplefilter("default") # Change the filter
    os.environ["PYTHONWARNINGS"] = "default" # Also affect
```

Finally, developers of interactive shells that run user code in a namespace other than `__main__` are advised to ensure that **DeprecationWarning** messages are made visible by default, using code like the following (where `user_ns` is the module used to execute code entered interactively):

```
import warnings
warnings.filterwarnings("default", category=DeprecationWarning,
                        module=user_ns.get("__
```

# Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning (even when warnings have been explicitly configured via the command line), then it is possible to suppress the warning using the `catch_warnings` context manager:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
```

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

## Testing Warnings

To test warnings raised by code, use the `catch_warnings` context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
```

```
warnings.simplefilter("always")
# Trigger a warning.
fxn()
# Verify some things
assert len(w) == 1
assert isinstance(w[-1].category, DeprecationWarning)
assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a `once/default` rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The `showwarning()` function in the module is also restored to its original value. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).

## Updating Code For New Versions of Dependencies

Warning categories that are primarily of interest to Python developers (rather than end users of applications written in Python) are ignored by default.

Notably, this “ignored by default” list includes

**DeprecationWarning** (for every module except `__main__`), which means developers should make sure to test their code with typically ignored warnings made visible in order to receive timely notifications of future breaking API changes (whether in the standard library or third party packages).

In the ideal case, the code will have a suitable test suite, and the test runner will take care of implicitly enabling all warnings when running tests (the test runner provided by the **unittest** module does this).

In less ideal cases, applications can be checked for use of deprecated interfaces by passing **-Wd** to the Python interpreter (this is shorthand for **-W default**) or setting `PYTHONWARNINGS=default` in the environment. This enables default handling for all warnings, including those that are ignored by default. To change what action is taken for encountered warnings you can change what argument is passed to **-W** (e.g. **-W error**). See the **-W** flag for more details on what is possible.

## Available Functions

```
warnings.warn(message, category=None, stacklevel=1,  
source=None, *, skip_file_prefixes=None)
```

Issue a warning, or maybe ignore it or raise an exception. The *category* argument, if given, must be a **warning category class**; it defaults to **UserWarning**. Alternatively, *message* can be a **Warning** instance, in which case *category* will be ignored and `message.__class__` will be used. In this case, the message text will be `str(message)`. This function raises an exception if the particular warning issued is changed into an error by the **warnings filter**. The *stacklevel* argument can be used by wrapper functions written in Python, like this:

```
def deprecated_api(message):  
    warnings.warn(message, DeprecationWarning, stack-
```

This makes the warning refer to `deprecated_api`'s caller, rather than to the source of `deprecated_api` itself (since

the latter would defeat the purpose of the warning message).

The *skip\_file\_prefixes* keyword argument can be used to indicate which stack frames are ignored when counting stack levels. This can be useful when you want the warning to always appear at call sites outside of a package when a constant *stacklevel* does not fit all call paths or is otherwise challenging to maintain. If supplied, it must be a tuple of strings. When prefixes are supplied, *stacklevel* is implicitly overridden to be `max(2, stacklevel)`. To cause a warning to be attributed to the caller from outside of the current package you might write:

```
# example/lower.py
_warn_skips = (os.path.dirname(__file__),)

def one_way(r_luxury_yacht=None, t_wobbler_mangrove=None,
            if_r_luxury_yacht=False):
    warnings.warn("Please migrate to t_wobbler_mangrove",
                  skip_file_prefixes=_warn_skips)

# example/higher.py
from . import lower

def another_way(**kw):
    lower.one_way(**kw)
```

This makes the warning refer to both the `example.lower.one_way()` and `package.higher.another_way()` call sites only from calling code living outside of `example` package.

*source*, if supplied, is the destroyed object which emitted a [ResourceWarning](#).

*Changed in version 3.6:* Added *source* parameter.

*Changed in version 3.12:* Added *skip\_file\_prefixes*.

`warnings.warn_explicit(message, category, filename, lineno,`

*module = None, registry = None, module\_globals = None, source = None)*

This is a low-level interface to the functionality of `warn()`, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the `__warningregistry__` dictionary of the module). The module name defaults to the filename with `.py` stripped; if no registry is passed, the warning is never suppressed. *message* must be a string and *category* a subclass of `Warning` or *message* may be a `Warning` instance, in which case *category* will be ignored.

*module\_globals*, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

*source*, if supplied, is the destroyed object which emitted a `ResourceWarning`.

*Changed in version 3.6:* Add the *source* parameter.

`warnings.showwarning(message, category, filename, lineno, file=None, line=None)`

Write a warning to a file. The default implementation calls `formatwarning(message, category, filename, lineno, line)` and writes the resulting string to *file*, which defaults to `sys.stderr`. You may replace this function with any callable by assigning to `warnings.showwarning`. *line* is a line of source code to be included in the warning message; if *line* is not supplied, `showwarning()` will try to read the line specified by *filename* and *lineno*.

`warnings.formatwarning(message, category, filename, lineno, line=None)`

Format a warning the standard way. This returns a string which may contain embedded newlines and ends in a newline. *line* is a line of source code to be included in the warning message; if *line* is not supplied, `formatwarning()`

will try to read the line specified by *filename* and *lineno*.

`warnings.filterwarnings(action, message="", category=Warning, module="", lineno=0, append=False)`

Insert an entry into the list of [warnings filter specifications](#). The entry is inserted at the front by default; if *append* is true, it is inserted at the end. This checks the types of the arguments, compiles the *message* and *module* regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a particular warning. Omitted arguments default to a value that matches everything.

`warnings.simplefilter(action, category=Warning, lineno=0, append=False)`

Insert a simple entry into the list of [warnings filter specifications](#). The meaning of the function parameters is as for [filterwarnings\(\)](#), but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

`warnings.resetwarnings()`

Reset the warnings filter. This discards the effect of all previous calls to [filterwarnings\(\)](#), including that of the **-W** command line options and calls to [simplefilter\(\)](#).

## Available Context Managers

`class warnings.catch_warnings(*, record=False, module=None, action=None, category=Warning, lineno=0, append=False)`

A context manager that copies and, upon exit, restores the warnings filter and the [showwarning\(\)](#) function. If the *record* argument is **False** (the default) the context manager returns **None** on entry. If *record* is **True**, a list is returned that is progressively populated with objects as seen by a custom [showwarning\(\)](#) function (which also suppresses output to `sys.stdout`). Each object in the list has attributes

with the same names as the arguments to `showwarning()`.

The *module* argument takes a module that will be used instead of the module returned when you import `warnings` whose filter will be protected. This argument exists primarily for testing the `warnings` module itself.

If the *action* argument is not `None`, the remaining arguments are passed to `simplefilter()` as if it were called immediately on entering the context.

### Note

The `catch_warnings` manager works by replacing and then later restoring the module's `showwarning()` function and internal list of filter specifications. This means the context manager is modifying global state and therefore is not thread-safe.

*Changed in version 3.11:* Added the *action*, *category*, *lineno*, and *append* parameters.

# dataclasses — Data Classes

**Source code:** [Lib/dataclasses.py](https://github.com/python/cpython/tree/3.12/Lib/dataclasses.py) [https://github.com/python/cpython/tree/3.12/Lib/dataclasses.py]

---

This module provides a decorator and functions for automatically adding generated [special methods](#) such as `__init__()` and `__repr__()` to user-defined classes. It was originally described in [PEP 557](#) [https://peps.python.org/pep-0557/].

The member variables to use in these generated methods are defined using [PEP 526](#) [https://peps.python.org/pep-0526/] type annotations. For example, this code:

```
from dataclasses import dataclass

@dataclass
class InventoryItem:
    """Class for keeping track of an item in inventory."""
    name: str
    unit_price: float
    quantity_on_hand: int = 0

    def total_cost(self) -> float:
        return self.unit_price * self.quantity_on_hand
```

will add, among other things, a `__init__()` that looks like:

```
def __init__(self, name: str, unit_price: float, quantity_on_hand: int):
    self.name = name
    self.unit_price = unit_price
    self.quantity_on_hand = quantity_on_hand
```

Note that this method is automatically added to the class: it is not directly specified in the `InventoryItem` definition shown above.

*New in version 3.7.*

## Module contents

`@dataclasses.dataclass(*, init=True, repr=True, eq=True, order=False, unsafe_hash=False, frozen=False, match_args=True, kw_only=False, slots=False, weakref_slot=False)`

This function is a [decorator](#) that is used to add generated [special methods](#) to classes, as described below.

The `dataclass()` decorator examines the class to find `fields`. A `field` is defined as a class variable that has a [type annotation](#). With two exceptions described below, nothing in `dataclass()` examines the type specified in the variable annotation.

The order of the fields in all of the generated methods is the order in which they appear in the class definition.

The `dataclass()` decorator will add various “dunder” methods to the class, described below. If any of the added methods already exist in the class, the behavior depends on the parameter, as documented below. The decorator returns the same class that it is called on; no new class is created.

If `dataclass()` is used just as a simple decorator with no parameters, it acts as if it has the default values documented in this signature. That is, these three uses of `dataclass()` are equivalent:

```
@dataclass
class C:
    ...
```

```
@dataclass()
class C:
    ...
```

```
@dataclass(init=True, repr=True, eq=True, order=False,
```

```
match_args=True, kw_only=False, slots=False)

class C:
    ...
```

The parameters to `dataclass()` are:

- `init`: If true (the default), a `__init__()` method will be generated.

If the class already defines `__init__()`, this parameter is ignored.

- `repr`: If true (the default), a `__repr__()` method will be generated. The generated repr string will have the class name and the name and repr of each field, in the order they are defined in the class. Fields that are marked as being excluded from the repr are not included. For example:

```
InventoryItem(name='widget',
unit_price=3.0, quantity_on_hand=10).
```

If the class already defines `__repr__()`, this parameter is ignored.

- `eq`: If true (the default), an `__eq__()` method will be generated. This method compares the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type.

If the class already defines `__eq__()`, this parameter is ignored.

- `order`: If true (the default is `False`), `__lt__()`, `__le__()`, `__gt__()`, and `__ge__()` methods will be generated. These compare the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type. If `order` is true and `eq` is false, a `ValueError` is raised.

If the class already defines any of `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`, then

`TypeError` is raised.

- `unsafe_hash`: If `False` (the default), a `__hash__()` method is generated according to how `eq` and `frozen` are set.

`__hash__()` is used by built-in `hash()`, and when objects are added to hashed collections such as dictionaries and sets. Having a `__hash__()` implies that instances of the class are immutable. Mutability is a complicated property that depends on the programmer's intent, the existence and behavior of `__eq__()`, and the values of the `eq` and `frozen` flags in the `dataclass()` decorator.

By default, `dataclass()` will not implicitly add a `__hash__()` method unless it is safe to do so. Neither will it add or change an existing explicitly defined `__hash__()` method. Setting the class attribute `__hash__ = None` has a specific meaning to Python, as described in the `__hash__()` documentation.

If `__hash__()` is not explicitly defined, or if it is set to `None`, then `dataclass()` may add an implicit `__hash__()` method. Although not recommended, you can force `dataclass()` to create a `__hash__()` method with `unsafe_hash=True`. This might be the case if your class is logically immutable but can nonetheless be mutated. This is a specialized use case and should be considered carefully.

Here are the rules governing implicit creation of a `__hash__()` method. Note that you cannot both have an explicit `__hash__()` method in your dataclass and set `unsafe_hash=True`; this will result in a `TypeError`.

If `eq` and `frozen` are both true, by default `dataclass()` will generate a `__hash__()` method for you. If `eq` is true and `frozen` is false, `__hash__()` will be set to `None`, marking it

unhashable (which it is, since it is mutable). If `eq` is false, `__hash__()` will be left untouched meaning the `__hash__()` method of the superclass will be used (if the superclass is `object`, this means it will fall back to id-based hashing).

- `frozen`: If true (the default is `False`), assigning to fields will generate an exception. This emulates read-only frozen instances. If `__setattr__()` or `__delattr__()` is defined in the class, then `TypeError` is raised. See the discussion below.
- `match_args`: If true (the default is `True`), the `__match_args__` tuple will be created from the list of parameters to the generated `__init__()` method (even if `__init__()` is not generated, see above). If false, or if `__match_args__` is already defined in the class, then `__match_args__` will not be generated.

*New in version 3.10.*

- `kw_only`: If true (the default value is `False`), then all fields will be marked as keyword-only. If a field is marked as keyword-only, then the only effect is that the `__init__()` parameter generated from a keyword-only field must be specified with a keyword when `__init__()` is called. There is no effect on any other aspect of dataclasses. See the [parameter](#) glossary entry for details. Also see the `KW_ONLY` section.

*New in version 3.10.*

- `slots`: If true (the default is `False`), `__slots__` attribute will be generated and new class will be returned instead of the original one. If `__slots__` is already defined in the class, then `TypeError` is raised.

*New in version 3.10.*

*Changed in version 3.11:* If a field name is already included in the `__slots__` of a

base class, it will not be included in the generated `__slots__` to prevent [overriding them](#). Therefore, do not use `__slots__` to retrieve the field names of a dataclass. Use [fields\(\)](#) instead. To be able to determine inherited slots, base class `__slots__` may be any iterable, but *not* an iterator.

- `weakref_slot`: If true (the default is `False`), add a slot named “`_weakref_`”, which is required to make an instance weakref-able. It is an error to specify `weakref_slot=True` without also specifying `slots=True`.

*New in version 3.11.*

`fields` may optionally specify a default value, using normal Python syntax:

```
@dataclass
class C:
    a: int          # 'a' has no default value
    b: int = 0      # assign a default value for 'b'
```

In this example, both `a` and `b` will be included in the added [\\_\\_init\\_\\_\(\)](#) method, which will be defined as:

```
def __init__(self, a: int, b: int = 0):
```

[TypeError](#) will be raised if a field without a default value follows a field with a default value. This is true whether this occurs in a single class, or as a result of class inheritance.

`dataclasses.field(*, default=MISSING, default_factory=MISSING, init=True, repr=True, hash=None, compare=True, metadata=None, kw_only=MISSING)`

For common and simple use cases, no other functionality is required. There are, however, some dataclass features that require additional per-field information. To satisfy this need for additional information, you can replace the default field

value with a call to the provided `field()` function. For example:

```
@dataclass
class C:
    mylist: list[int] = field(default_factory=list)

c = C()
c.mylist += [1, 2, 3]
```

As shown above, the `MISSING` value is a sentinel object used to detect if some parameters are provided by the user. This sentinel is used because `None` is a valid value for some parameters with a distinct meaning. No code should directly use the `MISSING` value.

The parameters to `field()` are:

- `default`: If provided, this will be the default value for this field. This is needed because the `field()` call itself replaces the normal position of the default value.
- `default_factory`: If provided, it must be a zero-argument callable that will be called when a default value is needed for this field. Among other purposes, this can be used to specify fields with mutable default values, as discussed below. It is an error to specify both `default` and `default_factory`.
- `init`: If true (the default), this field is included as a parameter to the generated `__init__()` method.
- `repr`: If true (the default), this field is included in the string returned by the generated `__repr__()` method.
- `hash`: This can be a bool or `None`. If true, this field is included in the generated `__hash__()` method. If `None` (the default), use the value of `compare`: this would normally be the expected behavior. A field should be considered in the hash if it's used for comparisons. Setting this value to anything other than

None is discouraged.

One possible reason to set `hash=False` but `compare=True` would be if a field is expensive to compute a hash value for, that field is needed for equality testing, and there are other fields that contribute to the type's hash value. Even if a field is excluded from the hash, it will still be used for comparisons.

- `compare`: If true (the default), this field is included in the generated equality and comparison methods (`__eq__()`, `__gt__()`, et al.).
- `metadata`: This can be a mapping or None. None is treated as an empty dict. This value is wrapped in `MappingProxyType()` to make it read-only, and exposed on the `Field` object. It is not used at all by Data Classes, and is provided as a third-party extension mechanism. Multiple third-parties can each have their own key, to use as a namespace in the metadata.
- `kw_only`: If true, this field will be marked as keyword-only. This is used when the generated `__init__()` method's parameters are computed.

*New in version 3.10.*

If the default value of a field is specified by a call to `field()`, then the class attribute for this field will be replaced by the specified `default` value. If no `default` is provided, then the class attribute will be deleted. The intent is that after the `dataclass()` decorator runs, the class attributes will all contain the default values for the fields, just as if the default value itself were specified. For example, after:

```
@dataclass
class C:
    x: int
    y: int = field(repr=False)
```

```
z: int = field(repr=False, default=10)
t: int = 20
```

The class attribute `C.z` will be `10`, the class attribute `C.t` will be `20`, and the class attributes `C.x` and `C.y` will not be set.

### `dataclasses.Field`

**Field** objects describe each defined field. These objects are created internally, and are returned by the `fields()` module-level method (see below). Users should never instantiate a **Field** object directly. Its documented attributes are:

- `name`: The name of the field.
- `type`: The type of the field.
- `default`, `default_factory`, `init`, `repr`, `hash`, `compare`, `metadata`, and `kw_only` have the identical meaning and values as they do in the `field()` function.

Other attributes may exist, but they are private and must not be inspected or relied on.

### `dataclasses.fields(class_or_instance)`

Returns a tuple of **Field** objects that define the fields for this dataclass. Accepts either a dataclass, or an instance of a dataclass. Raises **TypeError** if not passed a dataclass or instance of one. Does not return pseudo-fields which are `ClassVar` or `InitVar`.

### `dataclasses.asdict(obj, *, dict_factory=dict)`

Converts the dataclass `obj` to a dict (by using the factory function `dict_factory`). Each dataclass is converted to a dict of its fields, as `name: value` pairs. dataclasses, dicts, lists, and tuples are recursed into. Other objects are copied with `copy.deepcopy()`.

Example of using `asdict()` on nested dataclasses:

```
@dataclass
class Point:
    x: int
    y: int
```

```
@dataclass
class C:
    mylist: list[Point]
```

```
p = Point(10, 20)
assert asdict(p) == {'x': 10, 'y': 20}
```

```
c = C([Point(0, 0), Point(10, 4)])
assert asdict(c) == {'mylist': [{'x': 0, 'y': 0}, {
```

To create a shallow copy, the following workaround may be used:

```
dict((field.name, getattr(obj, field.name)) for field in dataclasses.fields(obj))
```

**asdict()** raises **TypeError** if **obj** is not a dataclass instance.

**dataclasses.astuple(obj, \*, tuple\_factory=tuple)**

Converts the dataclass **obj** to a tuple (by using the factory function **tuple\_factory**). Each dataclass is converted to a tuple of its field values. dataclasses, dicts, lists, and tuples are recursed into. Other objects are copied with **copy.deepcopy()**.

Continuing from the previous example:

```
assert astuple(p) == (10, 20)
assert astuple(c) == ((0, 0), (10, 4)),)
```

To create a shallow copy, the following workaround may be used:

```
tuple(getattr(obj, field.name) for field in dataclasses.fields(obj))
```

`astuple()` raises `TypeError` if `obj` is not a dataclass instance.

```
dataclasses.make_dataclass(cls_name, fields, *, bases=(),
                           namespace=None, init=True, repr=True, eq=True, order=False,
                           unsafe_hash=False, frozen=False, match_args=True, kw_only=False,
                           slots=False, weakref_slot=False, module=None)
```

Creates a new dataclass with name `cls_name`, fields as defined in `fields`, base classes as given in `bases`, and initialized with a namespace as given in `namespace`. `fields` is an iterable whose elements are each either `name`, `(name, type)`, or `(name, type, Field)`. If just `name` is supplied, `typing.Any` is used for `type`. The values of `init`, `repr`, `eq`, `order`, `unsafe_hash`, `frozen`, `match_args`, `kw_only`, `slots`, and `weakref_slot` have the same meaning as they do in `dataclass()`.

If `module` is defined, the `__module__` attribute of the dataclass is set to that value. By default, it is set to the module name of the caller.

This function is not strictly required, because any Python mechanism for creating a new class with `__annotations__` can then apply the `dataclass()` function to convert that class to a dataclass. This function is provided as a convenience. For example:

```
C = make_dataclass('C',
                  [ ('x', int),
                    'y',
                    ('z', int, field(default=5)) ],
                  namespace={'add_one': lambda self:
```

Is equivalent to:

```
@dataclass
class C:
    x: int
    y: 'typing.Any'
    z: int = 5
```

```
def add_one(self):  
    return self.x + 1
```

`dataclasses.replace(obj, /, **changes)`

Creates a new object of the same type as `obj`, replacing fields with values from `changes`. If `obj` is not a Data Class, raises `TypeError`. If values in `changes` do not specify fields, raises `TypeError`.

The newly returned object is created by calling the `__init__()` method of the dataclass. This ensures that `__post_init__()`, if present, is also called.

Init-only variables without default values, if any exist, must be specified on the call to `replace()` so that they can be passed to `__init__()` and `__post_init__()`.

It is an error for `changes` to contain any fields that are defined as having `init=False`. A `ValueError` will be raised in this case.

Be forewarned about how `init=False` fields work during a call to `replace()`. They are not copied from the source object, but rather are initialized in `__post_init__()`, if they're initialized at all. It is expected that `init=False` fields will be rarely and judiciously used. If they are used, it might be wise to have alternate class constructors, or perhaps a custom `replace()` (or similarly named) method which handles instance copying.

`dataclasses.is_dataclass(obj)`

Return `True` if its parameter is a dataclass or an instance of one, otherwise return `False`.

If you need to know if a class is an instance of a dataclass (and not a dataclass itself), then add a further check for `not isinstance(obj, type)`:

```
def is_dataclass_instance(obj):
```

```
return isinstance(obj) and not isinstance(obj,
```

### `dataclasses.MISSING`

A sentinel value signifying a missing default or `default_factory`.

### `dataclasses.KW_ONLY`

A sentinel value used as a type annotation. Any fields after a pseudo-field with the type of `KW_ONLY` are marked as keyword-only fields. Note that a pseudo-field of type `KW_ONLY` is otherwise completely ignored. This includes the name of such a field. By convention, a name of `_` is used for a `KW_ONLY` field. Keyword-only fields signify `__init__()` parameters that must be specified as keywords when the class is instantiated.

In this example, the fields `y` and `z` will be marked as keyword-only fields:

```
@dataclass
class Point:
    x: float
    _: KW_ONLY
    y: float
    z: float
```

```
p = Point(0, y=1.5, z=2.0)
```

In a single dataclass, it is an error to specify more than one field whose type is `KW_ONLY`.

*New in version 3.10.*

### *exception* `dataclasses.FrozenInstanceError`

Raised when an implicitly defined `__setattr__()` or `__delattr__()` is called on a dataclass which was defined with `frozen=True`. It is a subclass of `AttributeError`.

## Post-init processing

## `dataclasses.__post_init__()`

When defined on the class, it will be called by the generated `__init__()`, normally as `self.__post_init__()`. However, if any `InitVar` fields are defined, they will also be passed to `__post_init__()` in the order they were defined in the class. If no `__init__()` method is generated, then `__post_init__()` will not automatically be called.

Among other uses, this allows for initializing field values that depend on one or more other fields. For example:

```
@dataclass
class C:
    a: float
    b: float
    c: float = field(init=False)

    def __post_init__(self):
        self.c = self.a + self.b
```

The `__init__()` method generated by `dataclass()` does not call base class `__init__()` methods. If the base class has an `__init__()` method that has to be called, it is common to call this method in a `__post_init__()` method:

```
@dataclass
class Rectangle:
    height: float
    width: float

@dataclass
class Square(Rectangle):
    side: float

    def __post_init__(self):
        super().__init__(self.side, self.side)
```

Note, however, that in general the dataclass-generated `__init__()` methods don't need to be called, since the derived

`dataclass` will take care of initializing all fields of any base class that is a `dataclass` itself.

See the section below on `init-only` variables for ways to pass parameters to `__post_init__()`. Also see the warning about how `replace()` handles `init=False` fields.

## Class variables

One of the few places where `dataclass()` actually inspects the type of a field is to determine if a field is a class variable as defined in [PEP 526](https://peps.python.org/pep-0526/) [https://peps.python.org/pep-0526/]. It does this by checking if the type of the field is `typing.ClassVar`. If a field is a `ClassVar`, it is excluded from consideration as a field and is ignored by the `dataclass` mechanisms. Such `ClassVar` pseudo-fields are not returned by the module-level `fields()` function.

## Init-only variables

Another place where `dataclass()` inspects a type annotation is to determine if a field is an `init-only` variable. It does this by seeing if the type of a field is of type `dataclasses.InitVar`. If a field is an `InitVar`, it is considered a pseudo-field called an `init-only` field. As it is not a true field, it is not returned by the module-level `fields()` function. `Init-only` fields are added as parameters to the generated `__init__()` method, and are passed to the optional `__post_init__()` method. They are not otherwise used by `dataclasses`.

For example, suppose a field will be initialized from a database, if a value is not provided when creating the class:

```
@dataclass
class C:
    i: int
    j: int | None = None
    database: InitVar[DatabaseType | None] = None

    def __post_init__(self, database):
```

```
if self.j is None and database is not None:
    self.j = database.lookup('j')
```

```
c = C(10, database=my_database)
```

In this case, `fields()` will return `Field` objects for `i` and `j`, but not for `database`.

## Frozen instances

It is not possible to create truly immutable Python objects. However, by passing `frozen=True` to the `dataclass()` decorator you can emulate immutability. In that case, dataclasses will add `__setattr__()` and `__delattr__()` methods to the class. These methods will raise a `FrozenInstanceError` when invoked.

There is a tiny performance penalty when using `frozen=True`: `__init__()` cannot use simple assignment to initialize fields, and must use `object.__setattr__()`.

## Inheritance

When the dataclass is being created by the `dataclass()` decorator, it looks through all of the class's base classes in reverse MRO (that is, starting at `object`) and, for each dataclass that it finds, adds the fields from that base class to an ordered mapping of fields. After all of the base class fields are added, it adds its own fields to the ordered mapping. All of the generated methods will use this combined, calculated ordered mapping of fields. Because the fields are in insertion order, derived classes override base classes. An example:

```
@dataclass
class Base:
    x: Any = 15.0
    y: int = 0
```

```
@dataclass
```

```
class C(Base):
    z: int = 10
    x: int = 15
```

The final list of fields is, in order, `x`, `y`, `z`. The final type of `x` is `int`, as specified in class `C`.

The generated `__init__()` method for `C` will look like:

```
def __init__(self, x: int = 15, y: int = 0, z: int = 10)
```

## Re-ordering of keyword-only parameters in `__init__()`

After the parameters needed for `__init__()` are computed, any keyword-only parameters are moved to come after all regular (non-keyword-only) parameters. This is a requirement of how keyword-only parameters are implemented in Python: they must come after non-keyword-only parameters.

In this example, `Base.y`, `Base.w`, and `D.t` are keyword-only fields, and `Base.x` and `D.z` are regular fields:

```
@dataclass
class Base:
    x: Any = 15.0
    _: KW_ONLY
    y: int = 0
    w: int = 1
```

```
@dataclass
class D(Base):
    z: int = 10
    t: int = field(kw_only=True, default=0)
```

The generated `__init__()` method for `D` will look like:

```
def __init__(self, x: Any = 15.0, z: int = 10, *, y: int
```

Note that the parameters have been re-ordered from how they

appear in the list of fields: parameters derived from regular fields are followed by parameters derived from keyword-only fields.

The relative ordering of keyword-only parameters is maintained in the re-ordered `__init__()` parameter list.

## Default factory functions

If a `field()` specifies a `default_factory`, it is called with zero arguments when a default value for the field is needed. For example, to create a new instance of a list, use:

```
mylist: list = field(default_factory=list)
```

If a field is excluded from `__init__()` (using `init=False`) and the field also specifies `default_factory`, then the default factory function will always be called from the generated `__init__()` function. This happens because there is no other way to give the field an initial value.

## Mutable default values

Python stores default member variable values in class attributes. Consider this example, not using dataclasses:

```
class C:
    x = []
    def add(self, element):
        self.x.append(element)

o1 = C()
o2 = C()
o1.add(1)
o2.add(2)
assert o1.x == [1, 2]
assert o1.x is o2.x
```

Note that the two instances of class `C` share the same class variable `x`, as expected.

Using dataclasses, *if* this code was valid:

```
@dataclass
class D:
    x: list = []          # This code raises ValueError
    def add(self, element):
        self.x += element
```

it would generate code similar to:

```
class D:
    x = []
    def __init__(self, x=x):
        self.x = x
    def add(self, element):
        self.x += element
```

```
assert D().x is D().x
```

This has the same issue as the original example using class `C`. That is, two instances of class `D` that do not specify a value for `x` when creating a class instance will share the same copy of `x`. Because dataclasses just use normal Python class creation they also share this behavior. There is no general way for Data Classes to detect this condition. Instead, the `dataclass()` decorator will raise a **ValueError** if it detects an unhashable default parameter. The assumption is that if a value is unhashable, it is mutable. This is a partial solution, but it does protect against many common errors.

Using default factory functions is a way to create new instances of mutable types as default values for fields:

```
@dataclass
class D:
    x: list = field(default_factory=list)
```

```
assert D().x is not D().x
```

*Changed in version 3.11:* Instead of looking for and disallowing objects of type `list`, `dict`, or `set`, unhashable objects are now

not allowed as default values. Unhashability is used to approximate mutability.

## Descriptor-typed fields

Fields that are assigned [descriptor objects](#) as their default value have the following special behaviors:

- The value for the field passed to the dataclass's `__init__` method is passed to the descriptor's `__set__` method rather than overwriting the descriptor object.
- Similarly, when getting or setting the field, the descriptor's `__get__` or `__set__` method is called rather than returning or overwriting the descriptor object.
- To determine whether a field contains a default value, dataclasses will call the descriptor's `__get__` method using its class access form (i.e. `descriptor.__get__(obj=None, type=cls)`). If the descriptor returns a value in this case, it will be used as the field's default. On the other hand, if the descriptor raises [AttributeError](#) in this situation, no default value will be provided for the field.

```
class IntConversionDescriptor:
    def __init__(self, *, default):
        self._default = default

    def __set_name__(self, owner, name):
        self._name = "_" + name

    def __get__(self, obj, type):
        if obj is None:
            return self._default

        return getattr(obj, self._name, self._default)

    def __set__(self, obj, value):
        setattr(obj, self._name, int(value))
```

```
@dataclass
class InventoryItem:
    quantity_on_hand: IntConversionDescriptor = IntConversionDescriptor(100)

i = InventoryItem()
print(i.quantity_on_hand)    # 100
i.quantity_on_hand = 2.5     # calls __set__ with 2.5
print(i.quantity_on_hand)    # 2
```

Note that if a field is annotated with a descriptor type, but is not assigned a descriptor object as its default value, the field will act like a normal field.

# contextlib — Utilities for with-statement contexts

Source code: [Lib/contextlib.py](https://github.com/python/cpython/tree/3.12/Lib/contextlib.py) [https://github.com/python/cpython/tree/3.12/Lib/contextlib.py]

---

This module provides utilities for common tasks involving the `with` statement. For more information see also [Context Manager Types](#) and [With Statement Context Managers](#).

## Utilities

Functions and classes provided:

`class contextlib.AbstractContextManager`

An [abstract base class](#) for classes that implement `object.__enter__()` and `object.__exit__()`. A default implementation for `object.__enter__()` is provided which returns `self` while `object.__exit__()` is an abstract method which by default returns `None`. See also the definition of [Context Manager Types](#).

*New in version 3.6.*

`class contextlib.AbstractAsyncContextManager`

An [abstract base class](#) for classes that implement `object.__aenter__()` and `object.__aexit__()`. A default implementation for `object.__aenter__()` is provided which returns `self` while `object.__aexit__()` is an abstract method which by default returns `None`. See also the definition of [Asynchronous Context Managers](#).

*New in version 3.7.*

## @contextlib.contextmanager

This function is a **decorator** that can be used to define a factory function for **with** statement context managers, without needing to create a class or separate `__enter__()` and `__exit__()` methods.

While many objects natively support use in with statements, sometimes a resource needs to be managed that isn't a context manager in its own right, and doesn't implement a `close()` method for use with `contextlib.closing`

An abstract example would be the following to ensure correct resource management:

```
from contextlib import contextmanager

@contextmanager
def managed_resource(*args, **kwds):
    # Code to acquire resource, e.g.:
    resource = acquire_resource(*args, **kwds)
    try:
        yield resource
    finally:
        # Code to release resource, e.g.:
        release_resource(resource)
```

The function can then be used like this:

```
>>> with managed_resource(timeout=3600) as resource:
...     # Resource is released at the end of this block
...     # even if code in the block raises an exception
```

The function being decorated must return a **generator**-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the **with** statement's **as** clause, if any.

At the point where the generator yields, the block nested in the **with** statement is executed. The generator is then resumed after the block is exited. If an unhandled exception

occurs in the block, it is reraised inside the generator at the point where the yield occurred. Thus, you can use a `try...except...finally` statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the `with` statement that the exception has been handled, and execution will resume with the statement immediately following the `with` statement.

`contextmanager()` uses `ContextDecorator` so the context managers it creates can be used as decorators as well as in `with` statements. When used as a decorator, a new generator instance is implicitly created on each function call (this allows the otherwise “one-shot” context managers created by `contextmanager()` to meet the requirement that context managers support multiple invocations in order to be used as decorators).

*Changed in version 3.2:* Use of `ContextDecorator`.

`@contextlib.asynccontextmanager`

Similar to `contextmanager()`, but creates an `asynchronous context manager`.

This function is a `decorator` that can be used to define a factory function for `async with` statement asynchronous context managers, without needing to create a class or separate `__aenter__()` and `__aexit__()` methods. It must be applied to an `asynchronous generator` function.

A simple example:

```
from contextlib import asynccontextmanager

@asynccontextmanager
async def get_connection():
```

```

    conn = await acquire_db_connection()
    try:
        yield conn
    finally:
        await release_db_connection(conn)

async def get_all_users():
    async with get_connection() as conn:
        return conn.query('SELECT ...')

```

*New in version 3.7.*

Context managers defined with **`asynccontextmanager()`** can be used either as decorators or with **`async with`** statements:

```

import time
from contextlib import asynccontextmanager

@asynccontextmanager
async def timeit():
    now = time.monotonic()
    try:
        yield
    finally:
        print(f'it took {time.monotonic() - now} seconds')

@timeit()
async def main():
    # ... async code ...

```

When used as a decorator, a new generator instance is implicitly created on each function call. This allows the otherwise “one-shot” context managers created by **`asynccontextmanager()`** to meet the requirement that context managers support multiple invocations in order to be used as decorators.

*Changed in version 3.10:* Async context managers created with `asynccontextmanager()` can be used as decorators.

### `contextlib.closing(thing)`

Return a context manager that closes *thing* upon completion of the block. This is basically equivalent to:

```
from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
    finally:
        thing.close()
```

And lets you write code like this:

```
from contextlib import closing
from urllib.request import urlopen

with closing(urlopen('https://www.python.org')) as page:
    for line in page:
        print(line)
```

without needing to explicitly close `page`. Even if an error occurs, `page.close()` will be called when the `with` block is exited.

### `contextlib.aclosing(thing)`

Return an async context manager that calls the `aclose()` method of *thing* upon completion of the block. This is basically equivalent to:

```
from contextlib import asynccontextmanager

@asynccontextmanager
async def aclosing(thing):
    try:
```

```

        yield thing
    finally:
        await thing.aclose()

```

Significantly, `aclosing()` supports deterministic cleanup of async generators when they happen to exit early by **break** or an exception. For example:

```

from contextlib import aclosing

async with aclosing(my_generator()) as values:
    async for value in values:
        if value == 42:
            break

```

This pattern ensures that the generator’s async exit code is executed in the same context as its iterations (so that exceptions and context variables work as expected, and the exit code isn’t run after the lifetime of some task it depends on).

*New in version 3.10.*

`contextlib.nullcontext(enter_result=None)`

Return a context manager that returns *enter\_result* from `__enter__`, but otherwise does nothing. It is intended to be used as a stand-in for an optional context manager, for example:

```

def myfunction(arg, ignore_exceptions=False):
    if ignore_exceptions:
        # Use suppress to ignore all exceptions.
        cm = contextlib.suppress(Exception)
    else:
        # Do not ignore any exceptions, cm has no e
        cm = contextlib.nullcontext()
    with cm:
        # Do something

```

An example using *enter\_result*:

```
def process_file(file_or_path):
    if isinstance(file_or_path, str):
        # If string, open file
        cm = open(file_or_path)
    else:
        # Caller is responsible for closing file
        cm = nullcontext(file_or_path)

    with cm as file:
        # Perform processing on the file
```

It can also be used as a stand-in for [asynchronous context managers](#):

```
async def send_http(session=None):
    if not session:
        # If no http session, create it with aiohttp
        cm = aiohttp.ClientSession()
    else:
        # Caller is responsible for closing the session
        cm = nullcontext(session)

    async with cm as session:
        # Send http requests with session
```

*New in version 3.7.*

*Changed in version 3.10:* [asynchronous context manager](#) support was added.

`contextlib.suppress(*exceptions)`

Return a context manager that suppresses any of the specified exceptions if they occur in the body of a **with** statement and then resumes execution with the first statement following the end of the **with** statement.

As with any other mechanism that completely suppresses exceptions, this context manager should be used only to cover very specific errors where silently continuing with program

execution is known to be the right thing to do.

For example:

```
from contextlib import suppress

with suppress(FileNotFoundError):
    os.remove('somefile.tmp')

with suppress(FileNotFoundError):
    os.remove('someotherfile.tmp')
```

This code is equivalent to:

```
try:
    os.remove('somefile.tmp')
except FileNotFoundError:
    pass

try:
    os.remove('someotherfile.tmp')
except FileNotFoundError:
    pass
```

This context manager is [reentrant](#).

If the code within the **with** block raises an [ExceptionGroup](#), suppressed exceptions are removed from the group. If any exceptions in the group are not suppressed, a group containing them is re-raised.

*New in version 3.4.*

*Changed in version 3.12:* `suppress` now supports suppressing exceptions raised as part of an [ExceptionGroup](#).

`contextlib.redirect_stdout(new_target)`

Context manager for temporarily redirecting [sys.stdout](#) to another file or file-like object.

This tool adds flexibility to existing functions or classes whose output is hardwired to `stdout`.

For example, the output of `help()` normally is sent to `sys.stdout`. You can capture that output in a string by redirecting the output to an `io.StringIO` object. The replacement stream is returned from the `__enter__` method and so is available as the target of the `with` statement:

```
with redirect_stdout(io.StringIO()) as f:
    help(pow)
s = f.getvalue()
```

To send the output of `help()` to a file on disk, redirect the output to a regular file:

```
with open('help.txt', 'w') as f:
    with redirect_stdout(f):
        help(pow)
```

To send the output of `help()` to `sys.stderr`:

```
with redirect_stdout(sys.stderr):
    help(pow)
```

Note that the global side effect on `sys.stdout` means that this context manager is not suitable for use in library code and most threaded applications. It also has no effect on the output of subprocesses. However, it is still a useful approach for many utility scripts.

This context manager is [reentrant](#).

*New in version 3.4.*

`contextlib.redirect_stderr(new_target)`

Similar to `redirect_stdout()` but redirecting `sys.stderr` to another file or file-like object.

This context manager is [reentrant](#).

*New in version 3.5.*

`contextlib.chdir(path)`

Non parallel-safe context manager to change the current working directory. As this changes a global state, the working directory, it is not suitable for use in most threaded or async contexts. It is also not suitable for most non-linear code execution, like generators, where the program execution is temporarily relinquished – unless explicitly desired, you should not yield when this context manager is active.

This is a simple wrapper around `chdir()`, it changes the current working directory upon entering and restores the old one on exit.

This context manager is [reentrant](#).

*New in version 3.11.*

`class contextlib.ContextDecorator`

A base class that enables a context manager to also be used as a decorator.

Context managers inheriting from `ContextDecorator` have to implement `__enter__` and `__exit__` as normal. `__exit__` retains its optional exception handling even when used as a decorator.

`ContextDecorator` is used by `contextmanager()`, so you get this functionality automatically.

Example of `ContextDecorator`:

```
from contextlib import ContextDecorator

class mycontext(ContextDecorator):
    def __enter__(self):
        print('Starting')
        return self
```

```
def __exit__(self, *exc):
    print('Finishing')
    return False
```

The class can then be used like this:

```
>>> @mycontext()
... def function():
...     print('The bit in the middle')
...
>>> function()
Starting
The bit in the middle
Finishing
```

```
>>> with mycontext():
...     print('The bit in the middle')
...
Starting
The bit in the middle
Finishing
```

This change is just syntactic sugar for any construct of the following form:

```
def f():
    with cm():
        # Do stuff
```

ContextDecorator lets you instead write:

```
@cm()
def f():
    # Do stuff
```

It makes it clear that the `cm` applies to the whole function, rather than just a piece of it (and saving an indentation level is nice, too).

Existing context managers that already have a base class can

be extended by using `ContextDecorator` as a mixin class:

```
from contextlib import ContextDecorator

class mycontext(ContextBaseClass, ContextDecorator):
    def __enter__(self):
        return self

    def __exit__(self, *exc):
        return False
```

### Note

As the decorated function must be able to be called multiple times, the underlying context manager must support use in multiple **with** statements. If this is not the case, then the original construct with the explicit **with** statement inside the function should be used.

*New in version 3.2.*

*class* `contextlib.AsyncContextDecorator`

Similar to **ContextDecorator** but only for asynchronous functions.

Example of `AsyncContextDecorator`:

```
from asyncio import run
from contextlib import AsyncContextDecorator

class mycontext(AsyncContextDecorator):
    async def __aenter__(self):
        print('Starting')
        return self

    async def __aexit__(self, *exc):
        print('Finishing')
        return False
```

The class can then be used like this:

```
>>> @mycontext()
... async def function():
...     print('The bit in the middle')
...
>>> run(function())
Starting
The bit in the middle
Finishing

>>> async def function():
...     async with mycontext():
...         print('The bit in the middle')
...
>>> run(function())
Starting
The bit in the middle
Finishing
```

*New in version 3.10.*

*class* contextlib.ExitStack

A context manager that is designed to make it easy to programmatically combine other context managers and cleanup functions, especially those that are optional or otherwise driven by input data.

For example, a set of files may easily be handled in a single with statement as follows:

```
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for f
# All opened files will automatically be closed
# the with statement, even if attempts to open
# in the list raise an exception
```

The `__enter__()` method returns the `ExitStack` instance, and performs no additional operations.

Each instance maintains a stack of registered callbacks that are called in reverse order when the instance is closed (either explicitly or implicitly at the end of a `with` statement). Note that callbacks are *not* invoked implicitly when the context stack instance is garbage collected.

This stack model is used so that context managers that acquire their resources in their `__init__` method (such as file objects) can be handled correctly.

Since registered callbacks are invoked in the reverse order of registration, this ends up behaving as if multiple nested `with` statements had been used with the registered set of callbacks. This even extends to exception handling - if an inner callback suppresses or replaces an exception, then outer callbacks will be passed arguments based on that updated state.

This is a relatively low level API that takes care of the details of correctly unwinding the stack of exit callbacks. It provides a suitable foundation for higher level context managers that manipulate the exit stack in application specific ways.

*New in version 3.3.*

`enter_context(cm)`

Enters a new context manager and adds its `__exit__()` method to the callback stack. The return value is the result of the context manager's own `__enter__()` method.

These context managers may suppress exceptions just as they normally would if used directly as part of a `with` statement.

*Changed in version 3.11:* Raises `TypeError` instead of `AttributeError` if `cm` is not a context manager.

`push(exit)`

Adds a context manager's `__exit__()` method to the callback stack.

As `__enter__` is *not* invoked, this method can be used to cover part of an `__enter__()` implementation with a context manager's own `__exit__()` method.

If passed an object that is not a context manager, this method assumes it is a callback with the same signature as a context manager's `__exit__()` method and adds it directly to the callback stack.

By returning true values, these callbacks can suppress exceptions the same way context manager `__exit__()` methods can.

The passed in object is returned from the function, allowing this method to be used as a function decorator.

`callback(callback, /, *args, **kwargs)`

Accepts an arbitrary callback function and arguments and adds it to the callback stack.

Unlike the other methods, callbacks added this way cannot suppress exceptions (as they are never passed the exception details).

The passed in callback is returned from the function, allowing this method to be used as a function decorator.

`pop_all()`

Transfers the callback stack to a fresh `ExitStack` instance and returns it. No callbacks are invoked by this operation - instead, they will now be invoked when the new stack is closed (either explicitly or implicitly at the end of a `with` statement).

For example, a group of files can be opened as an “all or nothing” operation as follows:

```
with ExitStack() as stack:
```

```

files = [stack.enter_context(open(fname)) f
# Hold onto the close method, but don't call it
close_files = stack.pop_all().close
# If opening any file fails, all previously
# closed automatically. If all files are open
# they will remain open even after the with
# close_files() can then be invoked explicitly

```

## close()

Immediately unwinds the callback stack, invoking callbacks in the reverse order of registration. For any context managers and exit callbacks registered, the arguments passed in will indicate that no exception occurred.

## class contextlib.AsyncExitStack

An **asynchronous context manager**, similar to **ExitStack**, that supports combining both synchronous and asynchronous context managers, as well as having coroutines for cleanup logic.

The **close()** method is not implemented, **aclose()** must be used instead.

## coroutine enter\_async\_context(cm)

Similar to **enter\_context()** but expects an asynchronous context manager.

*Changed in version 3.11:* Raises **TypeError** instead of **AttributeError** if *cm* is not an asynchronous context manager.

## push\_async\_exit(exit)

Similar to **push()** but expects either an asynchronous context manager or a coroutine function.

## push\_async\_callback(callback, /, \*args, \*\*kwargs)

Similar to **callback()** but expects a coroutine

function.

*coroutine* `aclose()`

Similar to `close()` but properly handles awaitables.

Continuing the example for `asynccontextmanager()`:

```
async with AsyncExitStack() as stack:
    connections = [await stack.enter_async_context(
        for i in range(5)]
    # All opened connections will automatically be
    # the async with statement, even if attempts to
    # later in the list raise an exception.
```

*New in version 3.7.*

## Examples and Recipes

This section describes some examples and recipes for making effective use of the tools provided by `contextlib`.

### Supporting a variable number of context managers

The primary use case for `ExitStack` is the one given in the class documentation: supporting a variable number of context managers and other cleanup operations in a single `with` statement. The variability may come from the number of context managers needed being driven by user input (such as opening a user specified collection of files), or from some of the context managers being optional:

```
with ExitStack() as stack:
    for resource in resources:
        stack.enter_context(resource)
    if need_special_resource():
        special = acquire_special_resource()
        stack.callback(release_special_resource, special)
    # Perform operations that use the acquired resources
```

As shown, `ExitStack` also makes it quite easy to use `with` statements to manage arbitrary resources that don't natively support the context management protocol.

## Catching exceptions from `__enter__` methods

It is occasionally desirable to catch exceptions from an `__enter__` method implementation, *without* inadvertently catching exceptions from the `with` statement body or the context manager's `__exit__` method. By using `ExitStack` the steps in the context management protocol can be separated slightly in order to allow this:

```
stack = ExitStack()
try:
    x = stack.enter_context(cm)
except Exception:
    # handle __enter__ exception
else:
    with stack:
        # Handle normal case
```

Actually needing to do this is likely to indicate that the underlying API should be providing a direct resource management interface for use with `try/except/finally` statements, but not all APIs are well designed in that regard. When a context manager is the only resource management API provided, then `ExitStack` can make it easier to handle various situations that can't be handled directly in a `with` statement.

## Cleaning up in an `__enter__` implementation

As noted in the documentation of `ExitStack.push()`, this method can be useful in cleaning up an already allocated resource if later steps in the `__enter__()` implementation fail.

Here's an example of doing this for a context manager that accepts resource acquisition and release functions, along with an optional validation function, and maps them to the context management protocol:

```

from contextlib import contextmanager, AbstractContextManager

class ResourceManager(AbstractContextManager):

    def __init__(self, acquire_resource, release_resource):
        self.acquire_resource = acquire_resource
        self.release_resource = release_resource
        if check_resource_ok is None:
            def check_resource_ok(resource):
                return True
        self.check_resource_ok = check_resource_ok

    @contextmanager
    def _cleanup_on_error(self):
        with ExitStack() as stack:
            stack.push(self)
            yield
            # The validation check passed and didn't raise an exception
            # Accordingly, we want to keep the resource, and return it
            # back to our caller
            stack.pop_all()

    def __enter__(self):
        resource = self.acquire_resource()
        with self._cleanup_on_error():
            if not self.check_resource_ok(resource):
                msg = "Failed validation for {!r}"
                raise RuntimeError(msg.format(resource))
        return resource

    def __exit__(self, *exc_details):
        # We don't need to duplicate any of our resource management
        self.release_resource()

```

## Replacing any use of **try-finally** and flag variables

A pattern you will sometimes see is a `try-finally` statement with a flag variable to indicate whether or not the body of the

`finally` clause should be executed. In its simplest form (that can't already be handled just by using an `except` clause instead), it looks something like this:

```
cleanup_needed = True
try:
    result = perform_operation()
    if result:
        cleanup_needed = False
finally:
    if cleanup_needed:
        cleanup_resources()
```

As with any `try` statement based code, this can cause problems for development and review, because the setup code and the cleanup code can end up being separated by arbitrarily long sections of code.

**ExitStack** makes it possible to instead register a callback for execution at the end of a `with` statement, and then later decide to skip executing that callback:

```
from contextlib import ExitStack

with ExitStack() as stack:
    stack.callback(cleanup_resources)
    result = perform_operation()
    if result:
        stack.pop_all()
```

This allows the intended cleanup up behaviour to be made explicit up front, rather than requiring a separate flag variable.

If a particular application uses this pattern a lot, it can be simplified even further by means of a small helper class:

```
from contextlib import ExitStack

class Callback(ExitStack):
    def __init__(self, callback, /, *args, **kwds):
```

```

        super().__init__()
        self.callback(callback, *args, **kwds)

    def cancel(self):
        self.pop_all()

with Callback(cleanup_resources) as cb:
    result = perform_operation()
    if result:
        cb.cancel()

```

If the resource cleanup isn't already neatly bundled into a standalone function, then it is still possible to use the decorator form of `ExitStack.callback()` to declare the resource cleanup in advance:

```

from contextlib import ExitStack

with ExitStack() as stack:
    @stack.callback
    def cleanup_resources():
        ...
    result = perform_operation()
    if result:
        stack.pop_all()

```

Due to the way the decorator protocol works, a callback function declared this way cannot take any parameters. Instead, any resources to be released must be accessed as closure variables.

## Using a context manager as a function decorator

`ContextDecorator` makes it possible to use a context manager in both an ordinary `with` statement and also as a function decorator.

For example, it is sometimes useful to wrap functions or groups of statements with a logger that can track the time of entry and time of exit. Rather than writing both a function decorator and a context manager for the task, inheriting from `ContextDecorator` provides both capabilities in a single definition:

```
from contextlib import ContextDecorator
import logging

logging.basicConfig(level=logging.INFO)

class track_entry_and_exit(ContextDecorator):
    def __init__(self, name):
        self.name = name

    def __enter__(self):
        logging.info('Entering: %s', self.name)

    def __exit__(self, exc_type, exc, exc_tb):
        logging.info('Exiting: %s', self.name)
```

Instances of this class can be used as both a context manager:

```
with track_entry_and_exit('widget loader'):
    print('Some time consuming activity goes here')
    load_widget()
```

And also as a function decorator:

```
@track_entry_and_exit('widget loader')
def activity():
    print('Some time consuming activity goes here')
    load_widget()
```

Note that there is one additional limitation when using context managers as function decorators: there's no way to access the return value of `__enter__()`. If that value is needed, then it is still necessary to use an explicit `with` statement.

**See also**

**PEP 343** [<https://peps.python.org/pep-0343/>] - The “with” statement

The specification, background, and examples for the Python **with** statement.

# Single use, reusable and reentrant context managers

Most context managers are written in a way that means they can only be used effectively in a `with` statement once. These single use context managers must be created afresh each time they're used - attempting to use them a second time will trigger an exception or otherwise not work correctly.

This common limitation means that it is generally advisable to create context managers directly in the header of the `with` statement where they are used (as shown in all of the usage examples above).

Files are an example of effectively single use context managers, since the first `with` statement will close the file, preventing any further IO operations using that file object.

Context managers created using `contextmanager()` are also single use context managers, and will complain about the underlying generator failing to yield if an attempt is made to use them a second time:

```
>>> from contextlib import contextmanager
>>> @contextmanager
... def singleuse():
...     print("Before")
...     yield
...     print("After")
...
>>> cm = singleuse()
>>> with cm:
...     pass
...
Before
After
>>> with cm:
...     pass
...

```

```
Traceback (most recent call last):
...
RuntimeError: generator didn't yield
```

## Reentrant context managers

More sophisticated context managers may be “reentrant”. These context managers can not only be used in multiple **with** statements, but may also be used *inside* a **with** statement that is already using the same context manager.

**threading.RLock** is an example of a reentrant context manager, as are **suppress()**, **redirect\_stdout()**, and **chdir()**. Here’s a very simple example of reentrant use:

```
>>> from contextlib import redirect_stdout
>>> from io import StringIO
>>> stream = StringIO()
>>> write_to_stream = redirect_stdout(stream)
>>> with write_to_stream:
...     print("This is written to the stream rather than stdout")
...     with write_to_stream:
...         print("This is also written to the stream")
...
>>> print("This is written directly to stdout")
This is written directly to stdout
>>> print(stream.getvalue())
This is written to the stream rather than stdout
This is also written to the stream
```

Real world examples of reentrancy are more likely to involve multiple functions calling each other and hence be far more complicated than this example.

Note also that being reentrant is *not* the same thing as being thread safe. **redirect\_stdout()**, for example, is definitely not thread safe, as it makes a global modification to the system state by binding **sys.stdout** to a different stream.

## Reusable context managers

Distinct from both single use and reentrant context managers are “reusable” context managers (or, to be completely explicit, “reusable, but not reentrant” context managers, since reentrant context managers are also reusable). These context managers support being used multiple times, but will fail (or otherwise not work correctly) if the specific context manager instance has already been used in a containing with statement.

`threading.Lock` is an example of a reusable, but not reentrant, context manager (for a reentrant lock, it is necessary to use `threading.RLock` instead).

Another example of a reusable, but not reentrant, context manager is `ExitStack`, as it invokes *all* currently registered callbacks when leaving any with statement, regardless of where those callbacks were added:

```
>>> from contextlib import ExitStack
>>> stack = ExitStack()
>>> with stack:
...     stack.callback(print, "Callback: from first context")
...     print("Leaving first context")
...
Leaving first context
Callback: from first context
>>> with stack:
...     stack.callback(print, "Callback: from second context")
...     print("Leaving second context")
...
Leaving second context
Callback: from second context
>>> with stack:
...     stack.callback(print, "Callback: from outer context")
...     with stack:
...         stack.callback(print, "Callback: from inner context")
...         print("Leaving inner context")
...     print("Leaving outer context")
...
Leaving inner context
```

```
Callback: from inner context
Callback: from outer context
Leaving outer context
```

As the output from the example shows, reusing a single stack object across multiple with statements works correctly, but attempting to nest them will cause the stack to be cleared at the end of the innermost with statement, which is unlikely to be desirable behaviour.

Using separate **ExitStack** instances instead of reusing a single instance avoids that problem:

```
>>> from contextlib import ExitStack
>>> with ExitStack() as outer_stack:
...     outer_stack.callback(print, "Callback: from outer context")
...     with ExitStack() as inner_stack:
...         inner_stack.callback(print, "Callback: from inner context")
...         print("Leaving inner context")
...     print("Leaving outer context")
...
Leaving inner context
Callback: from inner context
Leaving outer context
Callback: from outer context
```

# abc — Abstract Base Classes

**Source code:** [Lib/abc.py](https://github.com/python/cpython/tree/3.12/Lib/abc.py) [https://github.com/python/cpython/tree/3.12/Lib/abc.py]

---

This module provides the infrastructure for defining [abstract base classes](#) (ABCs) in Python, as outlined in [PEP 3119](https://peps.python.org/pep-3119/) [https://peps.python.org/pep-3119/]; see the PEP for why this was added to Python. (See also [PEP 3141](https://peps.python.org/pep-3141/) [https://peps.python.org/pep-3141/] and the [numbers](#) module regarding a type hierarchy for numbers based on ABCs.)

The [collections](#) module has some concrete classes that derive from ABCs; these can, of course, be further derived. In addition, the [collections.abc](#) submodule has some ABCs that can be used to test whether a class or instance provides a particular interface, for example, if it is [hashable](#) or if it is a mapping.

This module provides the metaclass [ABCMeta](#) for defining ABCs and a helper class [ABC](#) to alternatively define ABCs through inheritance:

*class* abc.ABC

A helper class that has [ABCMeta](#) as its metaclass. With this class, an abstract base class can be created by simply deriving from [ABC](#) avoiding sometimes confusing metaclass usage, for example:

```
from abc import ABC

class MyABC(ABC):
    pass
```

Note that the type of [ABC](#) is still [ABCMeta](#), therefore inheriting from [ABC](#) requires the usual precautions regarding metaclass usage, as multiple inheritance may lead to

metaclass conflicts. One may also define an abstract base class by passing the metaclass keyword and using `ABCMeta` directly, for example:

```
from abc import ABCMeta

class MyABC(metaclass=ABCMeta):
    pass
```

*New in version 3.4.*

`class abc.ABCMeta`

Metaclass for defining Abstract Base Classes (ABCs).

Use this metaclass to create an ABC. An ABC can be subclassed directly, and then acts as a mix-in class. You can also register unrelated concrete classes (even built-in classes) and unrelated ABCs as “virtual subclasses” – these and their descendants will be considered subclasses of the registering ABC by the built-in `issubclass()` function, but the registering ABC won’t show up in their MRO (Method Resolution Order) nor will method implementations defined by the registering ABC be callable (not even via `super()`). <sup>1</sup>

Classes created with a metaclass of `ABCMeta` have the following method:

`register(subclass)`

Register *subclass* as a “virtual subclass” of this ABC. For example:

```
from abc import ABC

class MyABC(ABC):
    pass

MyABC.register(tuple)

assert issubclass(tuple, MyABC)
assert isinstance((), MyABC)
```

*Changed in version 3.3:* Returns the registered subclass, to allow usage as a class decorator.

*Changed in version 3.4:* To detect calls to `register()`, you can use the `get_cache_token()` function.

You can also override this method in an abstract base class:

`__subclasshook__(subclass)`

(Must be defined as a class method.)

Check whether *subclass* is considered a subclass of this ABC. This means that you can customize the behavior of `issubclass` further without the need to call `register()` on every class you want to consider a subclass of the ABC. (This class method is called from the `__subclasscheck__()` method of the ABC.)

This method should return `True`, `False` or `NotImplemented`. If it returns `True`, the *subclass* is considered a subclass of this ABC. If it returns `False`, the *subclass* is not considered a subclass of this ABC, even if it would normally be one. If it returns `NotImplemented`, the subclass check is continued with the usual mechanism.

For a demonstration of these concepts, look at this example ABC definition:

```
class Foo:
    def __getitem__(self, index):
        ...
    def __len__(self):
        ...
    def get_iterator(self):
        return iter(self)

class MyIterable(ABC):

    @abstractmethod
```

```

def __iter__(self):
    while False:
        yield None

def get_iterator(self):
    return self.__iter__()

@classmethod
def __subclasshook__(cls, C):
    if cls is MyIterable:
        if any("__iter__" in B.__dict__ for B in C.__mro__):
            return True
    return NotImplemented

MyIterable.register(Foo)

```

The `ABC` `MyIterable` defines the standard iterable method, `__iter__()`, as an abstract method. The implementation given here can still be called from subclasses. The `get_iterator()` method is also part of the `MyIterable` abstract base class, but it does not have to be overridden in non-abstract derived classes.

The `__subclasshook__()` class method defined here says that any class that has an `__iter__()` method in its `__dict__` (or in that of one of its base classes, accessed via the `__mro__` list) is considered a `MyIterable` too.

Finally, the last line makes `Foo` a virtual subclass of `MyIterable`, even though it does not define an `__iter__()` method (it uses the old-style iterable protocol, defined in terms of `__len__()` and `__getitem__()`). Note that this will not make `get_iterator` available as a method of `Foo`, so it is provided separately.

The `abc` module also provides the following decorator:

```
@abc.abstractmethod
```

A decorator indicating abstract methods.

Using this decorator requires that the class's metaclass is `ABCMeta` or is derived from it. A class that has a metaclass derived from `ABCMeta` cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract methods can be called using any of the normal 'super' call mechanisms. `abstractmethod()` may be used to declare abstract methods for properties and descriptors.

Dynamically adding abstract methods to a class, or attempting to modify the abstraction status of a method or class once it is created, are only supported using the `update_abstractmethods()` function. The `abstractmethod()` only affects subclasses derived using regular inheritance; "virtual subclasses" registered with the ABC's `register()` method are not affected.

When `abstractmethod()` is applied in combination with other method descriptors, it should be applied as the innermost decorator, as shown in the following usage examples:

```
class C(ABC):
    @abstractmethod
    def my_abstract_method(self, arg1):
        ...
    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, arg2):
        ...
    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(arg3):
        ...

    @property
    @abstractmethod
    def my_abstract_property(self):
        ...
    @my_abstract_property.setter
    @abstractmethod
```

```

def my_abstract_property(self, val):
    ...

    @abstractmethod
    def _get_x(self):
        ...

    @abstractmethod
    def _set_x(self, val):
        ...

    x = property(_get_x, _set_x)

```

In order to correctly interoperate with the abstract base class machinery, the descriptor must identify itself as abstract using `__isabstractmethod__`. In general, this attribute should be `True` if any of the methods used to compose the descriptor are abstract. For example, Python's built-in `property` does the equivalent of:

```

class Descriptor:
    ...
    @property
    def __isabstractmethod__(self):
        return any(getattr(f, '__isabstractmethod__'
                           f in (self._fget, self._fset, se

```

## Note

Unlike Java abstract methods, these abstract methods may have an implementation. This implementation can be called via the `super()` mechanism from the class that overrides it. This could be useful as an end-point for a super-call in a framework that uses cooperative multiple-inheritance.

The `abc` module also supports the following legacy decorators:

`@abc.abstractclassmethod`

*New in version 3.2.*

*Deprecated since version 3.3:* It is now possible to use `classmethod` with `abstractmethod()`, making this decorator redundant.

A subclass of the built-in `classmethod()`, indicating an abstract classmethod. Otherwise it is similar to `abstractmethod()`.

This special case is deprecated, as the `classmethod()` decorator is now correctly identified as abstract when applied to an abstract method:

```
class C(ABC):
    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, arg):
        ...
```

`@abc.abstractstaticmethod`

*New in version 3.2.*

*Deprecated since version 3.3:* It is now possible to use `staticmethod` with `abstractmethod()`, making this decorator redundant.

A subclass of the built-in `staticmethod()`, indicating an abstract staticmethod. Otherwise it is similar to `abstractmethod()`.

This special case is deprecated, as the `staticmethod()` decorator is now correctly identified as abstract when applied to an abstract method:

```
class C(ABC):
    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(arg):
        ...
```

`@abc.abstractproperty`

*Deprecated since version 3.3:* It is now possible to use `property`, `property.getter()`, `property.setter()` and `property.deleter()` with `abstractmethod()`, making this decorator redundant.

A subclass of the built-in `property()`, indicating an abstract property.

This special case is deprecated, as the `property()` decorator is now correctly identified as abstract when applied to an abstract method:

```
class C(ABC):
    @property
    @abstractmethod
    def my_abstract_property(self):
        ...
```

The above example defines a read-only property; you can also define a read-write abstract property by appropriately marking one or more of the underlying methods as abstract:

```
class C(ABC):
    @property
    def x(self):
        ...

    @x.setter
    @abstractmethod
    def x(self, val):
        ...
```

If only some components are abstract, only those components need to be updated to create a concrete property in a subclass:

```
class D(C):
    @C.x.setter
    def x(self, val):
        ...
```

The `abc` module also provides the following functions:

`abc.get_cache_token()`

Returns the current abstract base class cache token.

The token is an opaque object (that supports equality testing) identifying the current version of the abstract base class cache for virtual subclasses. The token changes with every call to `ABCMeta.register()` on any ABC.

*New in version 3.4.*

`abc.update_abstractmethods(cls)`

A function to recalculate an abstract class's abstraction status. This function should be called if a class's abstract methods have been implemented or changed after it was created. Usually, this function should be called from within a class decorator.

Returns `cls`, to allow usage as a class decorator.

If `cls` is not an instance of `ABCMeta`, does nothing.

### Note

This function assumes that `cls`'s superclasses are already updated. It does not update any subclasses.

*New in version 3.10.*

## Footnotes

1

C++ programmers should note that Python's virtual base class concept is not the same as C++'s.

# atexit — Exit handlers

---

The `atexit` module defines functions to register and unregister cleanup functions. Functions thus registered are automatically executed upon normal interpreter termination. `atexit` runs these functions in the *reverse* order in which they were registered; if you register `A`, `B`, and `C`, at interpreter termination time they will be run in the order `C`, `B`, `A`.

**Note:** The functions registered via this module are not called when the program is killed by a signal not handled by Python, when a Python fatal internal error is detected, or when `os._exit()` is called.

**Note:** The effect of registering or unregistering functions from within a cleanup function is undefined.

*Changed in version 3.7:* When used with C-API subinterpreters, registered functions are local to the interpreter they were registered in.

`atexit.register(func, *args, **kwargs)`

Register *func* as a function to be executed at termination. Any optional arguments that are to be passed to *func* must be passed as arguments to `register()`. It is possible to register the same function and arguments more than once.

At normal program termination (for instance, if `sys.exit()` is called or the main module's execution completes), all functions registered are called in last in, first out order. The assumption is that lower level modules will normally be imported before higher level modules and thus must be cleaned up later.

If an exception is raised during execution of the exit handlers,

a traceback is printed (unless `SystemExit` is raised) and the exception information is saved. After all exit handlers have had a chance to run, the last exception to be raised is re-raised.

This function returns *func*, which makes it possible to use it as a decorator.

### Warning

Starting new threads or calling `os.fork()` from a registered function can lead to race condition between the main Python runtime thread freeing thread states while internal `threading` routines or the new process try to use that state. This can lead to crashes rather than clean shutdown.

*Changed in version 3.12:* Attempts to start a new thread or `os.fork()` a new process in a registered function now leads to `RuntimeError`.

### `atexit.unregister(func)`

Remove *func* from the list of functions to be run at interpreter shutdown. `unregister()` silently does nothing if *func* was not previously registered. If *func* has been registered more than once, every occurrence of that function in the `atexit` call stack will be removed. Equality comparisons (`==`) are used internally during unregistration, so function references do not need to have matching identities.

See also

### Module `readline`

Useful example of `atexit` to read and write `readline` history files.

## `atexit` Example

The following simple example demonstrates how a module can initialize a counter from a file when it is imported and save the counter's updated value automatically when the program terminates without relying on the application making an explicit call into this module at termination.

```
try:
    with open('counterfile') as infile:
        _count = int(infile.read())
except FileNotFoundError:
    _count = 0

def incrcounter(n):
    global _count
    _count = _count + n

def savecounter():
    with open('counterfile', 'w') as outfile:
        outfile.write('%d' % _count)

import atexit

atexit.register(savecounter)
```

Positional and keyword arguments may also be passed to `register()` to be passed along to the registered function when it is called:

```
def goodbye(name, adjective):
    print('Goodbye %s, it was %s to meet you.' % (name,

import atexit

atexit.register(goodbye, 'Donny', 'nice')
# or:
atexit.register(goodbye, adjective='nice', name='Donny')
```

Usage as a [decorator](#):

```
import atexit
```

```
@atexit.register
def goodbye():
    print('You are now leaving the Python sector.')
```

This only works with functions that can be called without arguments.

# traceback — Print or retrieve a stack traceback

**Source code:** [Lib/traceback.py](https://github.com/python/cpython/tree/3.12/Lib/traceback.py) [https://github.com/python/cpython/tree/3.12/Lib/traceback.py]

---

This module provides a standard interface to extract, format and print stack traces of Python programs. It exactly mimics the behavior of the Python interpreter when it prints a stack trace. This is useful when you want to print stack traces under program control, such as in a “wrapper” around the interpreter.

The module uses traceback objects — these are objects of type `types.TracebackType`, which are assigned to the `__traceback__` field of `BaseException` instances.

**See also**

**Module `faulthandler`**

Used to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal.

**Module `pdb`**

Interactive source code debugger for Python programs.

The module defines the following functions:

`traceback.print_tb(tb, limit=None, file=None)`

Print up to *limit* stack trace entries from traceback object *tb* (starting from the caller’s frame) if *limit* is positive.

Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. If *file* is omitted or `None`, the output goes to `sys.stderr`; otherwise it should be an open file or file-like object to receive the output.

*Changed in version 3.5:* Added negative *limit* support.

```
traceback.print_exception(exc, /, [value, tb, ]limit=None,  
file=None, chain=True)
```

Print exception information and stack trace entries from traceback object *tb* to *file*. This differs from `print_tb()` in the following ways:

- if *tb* is not `None`, it prints a header `Traceback (most recent call last):`
- it prints the exception type and *value* after the stack trace
- if `type(value)` is `SyntaxError` and *value* has the appropriate format, it prints the line where the syntax error occurred with a caret indicating the approximate position of the error.

Since Python 3.10, instead of passing *value* and *tb*, an exception object can be passed as the first argument. If *value* and *tb* are provided, the first argument is ignored in order to provide backwards compatibility.

The optional *limit* argument has the same meaning as for `print_tb()`. If *chain* is true (the default), then chained exceptions (the `__cause__` or `__context__` attributes of the exception) will be printed as well, like the interpreter itself does when printing an unhandled exception.

*Changed in version 3.5:* The *etype* argument is ignored and inferred from the type of *value*.

*Changed in version 3.10:* The *etype* parameter has been renamed to *exc* and is now positional-only.

```
traceback.print_exc(limit=None, file=None, chain=True)
```

This is a shorthand for

```
print_exception(sys.exception(), limit, file,  
chain).
```

`traceback.print_last(limit=None, file=None, chain=True)`

This is a shorthand for

`print_exception(sys.last_exc, limit, file, chain)`. In general it will work only after an exception has reached an interactive prompt (see [sys.last\\_exc](#)).

`traceback.print_stack(f=None, limit=None, file=None)`

Print up to *limit* stack trace entries (starting from the invocation point) if *limit* is positive. Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. The optional *f* argument can be used to specify an alternate stack frame to start. The optional *file* argument has the same meaning as for [print\\_tb\(\)](#).

*Changed in version 3.5:* Added negative *limit* support.

`traceback.extract_tb(tb, limit=None)`

Return a [StackSummary](#) object representing a list of “pre-processed” stack trace entries extracted from the traceback object *tb*. It is useful for alternate formatting of stack traces. The optional *limit* argument has the same meaning as for [print\\_tb\(\)](#). A “pre-processed” stack trace entry is a [FrameSummary](#) object containing attributes **filename**, **lineno**, **name**, and **line** representing the information that is usually printed for a stack trace. The **line** is a string with leading and trailing whitespace stripped; if the source is not available it is `None`.

`traceback.extract_stack(f=None, limit=None)`

Extract the raw traceback from the current stack frame. The return value has the same format as for [extract\\_tb\(\)](#). The optional *f* and *limit* arguments have the same meaning as for [print\\_stack\(\)](#).

`traceback.format_list(extracted_list)`

Given a list of tuples or [FrameSummary](#) objects as returned by [extract\\_tb\(\)](#) or [extract\\_stack\(\)](#), return a list of

strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not `None`.

`traceback.format_exception_only(exc, [, value])`

Format the exception part of a traceback using an exception value such as given by `sys.last_value`. The return value is a list of strings, each ending in a newline. The list contains the exception's message, which is normally a single string; however, for `SyntaxError` exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. Following the message, the list contains the exception's `notes`.

Since Python 3.10, instead of passing *value*, an exception object can be passed as the first argument. If *value* is provided, the first argument is ignored in order to provide backwards compatibility.

*Changed in version 3.10:* The *etype* parameter has been renamed to *exc* and is now positional-only.

*Changed in version 3.11:* The returned list now includes any notes attached to the exception.

`traceback.format_exception(exc, /, [value, tb, ]limit=None, chain=True)`

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to `print_exception()`. The return value is a list of strings, each ending in a newline and some containing internal newlines. When these lines are concatenated and printed, exactly the same text is printed as does `print_exception()`.

*Changed in version 3.5:* The *etype* argument is ignored and inferred from the type of *value*.

*Changed in version 3.10:* This function's behavior and signature were modified to match `print_exception()`.

`traceback.format_exc(limit=None, chain=True)`

This is like `print_exc(limit)` but returns a string instead of printing to a file.

`traceback.format_tb(tb, limit=None)`

A shorthand for `format_list(extract_tb(tb, limit))`.

`traceback.format_stack(f=None, limit=None)`

A shorthand for `format_list(extract_stack(f, limit))`.

`traceback.clear_frames(tb)`

Clears the local variables of all the stack frames in a traceback `tb` by calling the `clear()` method of each frame object.

*New in version 3.4.*

`traceback.walk_stack(f)`

Walk a stack following `f.f_back` from the given frame, yielding the frame and line number for each frame. If `f` is `None`, the current stack is used. This helper is used with `StackSummary.extract()`.

*New in version 3.5.*

`traceback.walk_tb(tb)`

Walk a traceback following `tb_next` yielding the frame and line number for each frame. This helper is used with `StackSummary.extract()`.

*New in version 3.5.*

The module also defines the following classes:

## TracebackException Objects

*New in version 3.5.*

**TracebackException** objects are created from actual exceptions to capture data for later printing in a lightweight fashion.

```
class traceback.TracebackException(exc_type, exc_value,  
exc_traceback, *, limit=None, lookup_lines=True,  
capture_locals=False, compact=False, max_group_width=15,  
max_group_depth=10)
```

Capture an exception for later rendering. *limit*, *lookup\_lines* and *capture\_locals* are as for the **StackSummary** class.

If *compact* is true, only data that is required by **TracebackException**'s `format` method is saved in the class attributes. In particular, the `__context__` field is calculated only if `__cause__` is `None` and `__suppress_context__` is false.

Note that when locals are captured, they are also shown in the traceback.

*max\_group\_width* and *max\_group\_depth* control the formatting of exception groups (see **BaseExceptionGroup**). The depth refers to the nesting level of the group, and the width refers to the size of a single exception group's exceptions array. The formatted output is truncated when either limit is exceeded.

*Changed in version 3.10:* Added the *compact* parameter.

*Changed in version 3.11:* Added the *max\_group\_width* and *max\_group\_depth* parameters.

`__cause__`

A **TracebackException** of the original

`__cause__`.

`_context_`

A `TracebackException` of the original  
`__context__`.

`exceptions`

If `self` represents an `ExceptionGroup`, this field holds a list of `TracebackException` instances representing the nested exceptions. Otherwise it is `None`.

*New in version 3.11.*

`_suppress_context_`

The `__suppress_context__` value from the original exception.

`_notes_`

The `__notes__` value from the original exception, or `None` if the exception does not have any notes. If it is not `None` is it formatted in the traceback after the exception string.

*New in version 3.11.*

`stack`

A `StackSummary` representing the traceback.

`exc_type`

The class of the original traceback.

`filename`

For syntax errors - the file name where the error occurred.

`lineno`

For syntax errors - the line number where the error occurred.

`end_lineno`

For syntax errors - the end line number where the error occurred. Can be `None` if not present.

*New in version 3.10.*

`text`

For syntax errors - the text where the error occurred.

`offset`

For syntax errors - the offset into the text where the error occurred.

`end_offset`

For syntax errors - the end offset into the text where the error occurred. Can be `None` if not present.

*New in version 3.10.*

`msg`

For syntax errors - the compiler error message.

*classmethod* `from_exception(exc, *, limit=None, lookup_lines=True, capture_locals=False)`

Capture an exception for later rendering. *limit*, *lookup\_lines* and *capture\_locals* are as for the [StackSummary](#) class.

Note that when locals are captured, they are also shown in the traceback.

`print(*, file=None, chain=True)`

Print to *file* (default `sys.stderr`) the exception information returned by [format\(\)](#).

*New in version 3.11.*

`format(*, chain=True)`

Format the exception.

If *chain* is not `True`, `__cause__` and `__context__` will not be formatted.

The return value is a generator of strings, each ending in a newline and some containing internal newlines.

`print_exception()` is a wrapper around this method which just prints the lines to a file.

`format_exception_only()`

Format the exception part of the traceback.

The return value is a generator of strings, each ending in a newline.

The generator emits the exception's message followed by its notes (if it has any). The exception message is normally a single string; however, for `SyntaxError` exceptions, it consists of several lines that (when printed) display detailed information about where the syntax error occurred.

*Changed in version 3.11:* The exception's notes are now included in the output.

## StackSummary Objects

*New in version 3.5.*

`StackSummary` objects represent a call stack ready for formatting.

`class traceback.StackSummary`

`classmethod extract(frame_gen, *, limit=None,  
lookup_lines=True, capture_locals=False)`

Construct a `StackSummary` object from a frame generator (such as is returned by `walk_stack()` or

`walk_tb()`).

If *limit* is supplied, only this many frames are taken from *frame\_gen*. If *lookup\_lines* is `False`, the returned **FrameSummary** objects will not have read their lines in yet, making the cost of creating the **StackSummary** cheaper (which may be valuable if it may not actually get formatted). If *capture\_locals* is `True` the local variables in each **FrameSummary** are captured as object representations.

*Changed in version 3.12:* Exceptions raised from `repr()` on a local variable (when *capture\_locals* is `True`) are no longer propagated to the caller.

*classmethod* `from_list(a_list)`

Construct a **StackSummary** object from a supplied list of **FrameSummary** objects or old-style list of tuples. Each tuple should be a 4-tuple with filename, lineno, name, line as the elements.

`format()`

Returns a list of strings ready for printing. Each string in the resulting list corresponds to a single frame from the stack. Each string ends in a newline; the strings may contain internal newlines as well, for those items with source text lines.

For long sequences of the same frame and line, the first few repetitions are shown, followed by a summary line stating the exact number of further repetitions.

*Changed in version 3.6:* Long sequences of repeated frames are now abbreviated.

`format_frame_summary(frame_summary)`

Returns a string for printing one of the frames involved in the stack. This method is called for each **FrameSummary** object to be printed by

`StackSummary.format()`. If it returns `None`, the frame is omitted from the output.

*New in version 3.11.*

## FrameSummary Objects

*New in version 3.5.*

A **FrameSummary** object represents a single frame in a traceback.

```
class traceback.FrameSummary(filename, lineno, name,  
lookup_line = True, locals = None, line = None)
```

Represent a single frame in the traceback or stack that is being formatted or printed. It may optionally have a stringified version of the frames locals included in it. If `lookup_line` is `False`, the source code is not looked up until the **FrameSummary** has the `line` attribute accessed (which also happens when casting it to a tuple). `line` may be directly provided, and will prevent line lookups happening at all. `locals` is an optional local variable dictionary, and if supplied the variable representations are stored in the summary for later display.

## Traceback Examples

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the `code` module.

```
import sys, traceback  
  
def run_user_code(envdir):  
    source = input(">>> ")  
    try:  
        exec(source, envdir)  
    except Exception:
```

```
print("Exception in user code:")
print("-"*60)
traceback.print_exc(file=sys.stdout)
print("-"*60)
```

```
envdir = {}
while True:
    run_user_code(envdir)
```

The following example demonstrates the different ways to print and format the exception and traceback:

```
import sys, traceback

def lumberjack():
    bright_side_of_life()

def bright_side_of_life():
    return tuple()[0]

try:
    lumberjack()
except IndexError:
    exc = sys.exception()
    print("*** print_tb:")
    traceback.print_tb(exc.__traceback__, limit=1, file=sys.stdout)
    print("*** print_exception:")
    traceback.print_exception(exc, limit=2, file=sys.stdout)
    print("*** print_exc:")
    traceback.print_exc(limit=2, file=sys.stdout)
    print("*** format_exc, first and last line:")
    formatted_lines = traceback.format_exc().splitlines()
    print(formatted_lines[0])
    print(formatted_lines[-1])
    print("*** format_exception:")
    print(repr(traceback.format_exception(exc)))
    print("*** extract_tb:")
    print(repr(traceback.extract_tb(exc.__traceback__)))
    print("*** format_tb:")
```

```
print(repr(traceback.format_tb(exc.__traceback__)))
print("*** tb_lineno:", exc.__traceback__.tb_lineno)
```

The output for the example would look similar to this:

```
*** print_tb:
  File "<doctest...>", line 10, in <module>
    lumberjack()
*** print_exception:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
  File "<doctest...>", line 4, in lumberjack
    bright_side_of_life()
IndexError: tuple index out of range
*** print_exc:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
  File "<doctest...>", line 4, in lumberjack
    bright_side_of_life()
IndexError: tuple index out of range
*** format_exc, first and last line:
Traceback (most recent call last):
IndexError: tuple index out of range
*** format_exception:
['Traceback (most recent call last):\n',
 '  File "<doctest default[0]>", line 10, in <module>\n',
 '  File "<doctest default[0]>", line 4, in lumberjack\n',
 '  File "<doctest default[0]>", line 7, in bright_side_of_life\n',
 'IndexError: tuple index out of range\n']
*** extract_tb:
[<FrameSummary file <doctest...>, line 10 in <module>>,
 <FrameSummary file <doctest...>, line 4 in lumberjack>,
 <FrameSummary file <doctest...>, line 7 in bright_side_of_life>]
*** format_tb:
['  File "<doctest default[0]>", line 10, in <module>\n',
 '  File "<doctest default[0]>", line 4, in lumberjack\n',
 '  File "<doctest default[0]>", line 7, in bright_side_of_life\n']
```

```
*** tb_lineno: 10
```

The following example shows the different ways to print and format the stack:

```
>>> import traceback
>>> def another_function():
...     lumberstack()
...
>>> def lumberstack():
...     traceback.print_stack()
...     print(repr(traceback.extract_stack()))
...     print(repr(traceback.format_stack()))
...
>>> another_function()
File "<doctest>", line 10, in <module>
    another_function()
File "<doctest>", line 3, in another_function
    lumberstack()
File "<doctest>", line 6, in lumberstack
    traceback.print_stack()
[('<doctest>', 10, '<module>', 'another_function()'),
  ('<doctest>', 3, 'another_function', 'lumberstack()'),
  ('<doctest>', 7, 'lumberstack', 'print(repr(traceback.e
['  File "<doctest>", line 10, in <module>\n    another_
'  File "<doctest>", line 3, in another_function\n    l
'  File "<doctest>", line 8, in lumberstack\n    print(
```

This last example demonstrates the final few formatting functions:

```
>>> import traceback
>>> traceback.format_list([('spam.py', 3, '<module>', 's
...                        ('eggs.py', 42, 'eggs', 'retu
['  File "spam.py", line 3, in <module>\n    spam.eggs()
'  File "eggs.py", line 42, in eggs\n    return "bacon"
>>> an_error = IndexError('tuple index out of range')
>>> traceback.format_exception_only(type(an_error), an_e
['IndexError: tuple index out of range\n']
```

# \_\_future\_\_ — Future statement definitions

**Source code:** [Lib/\\_future\\_.py](https://github.com/python/cpython/tree/3.12/Lib/_future_.py) [https://github.com/python/cpython/tree/3.12/Lib/\_future\_.py]

---

`__future__` is a real module, and serves three purposes:

- To avoid confusing existing tools that analyze import statements and expect to find the modules they're importing.
- To ensure that [future statements](#) run under releases prior to 2.1 at least yield runtime exceptions (the import of `__future__` will fail, because there was no module of that name prior to 2.1).
- To document when incompatible changes were introduced, and when they will be — or were — made mandatory. This is a form of executable documentation, and can be inspected programmatically via importing `__future__` and examining its contents.

Each statement in `__future__.py` is of the form:

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease,
                        CompilerFlag)
```

where, normally, *OptionalRelease* is less than *MandatoryRelease*, and both are 5-tuples of the same form as [sys.version\\_info](#):

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
 PY_MINOR_VERSION, # the 1; an int
 PY_MICRO_VERSION, # the 0; an int
 PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or "final"
 PY_RELEASE_SERIAL # the 3; an int
)
```

*OptionalRelease* records the first release in which the feature was accepted.

In the case of a *MandatoryRelease* that has not yet occurred, *MandatoryRelease* predicts the release in which the feature will become part of the language.

Else *MandatoryRelease* records when the feature became part of the language; in releases at or after that, modules no longer need a future statement to use the feature in question, but may continue to use such imports.

*MandatoryRelease* may also be `None`, meaning that a planned feature got dropped.

Instances of class **`_Feature`** have two corresponding methods, **`getOptionalRelease()`** and **`getMandatoryRelease()`**.

*CompilerFlag* is the (bitfield) flag that should be passed in the fourth argument to the built-in function **`compile()`** to enable the feature in dynamically compiled code. This flag is stored in the **`compiler_flag`** attribute on **`_Feature`** instances.

No feature description will ever be deleted from **`__future__`**. Since its introduction in Python 2.1 the following features have found their way into the language using this mechanism:

### **mandatory in**

**`Python 2.5`** **`from __future__ import nested_scopes`** Dynamically Nested Scopes

**`Python 2.5`** **`from __future__ import generators`** Simple Generators

**`Python 2.8`** **`from __future__ import division`** Changing the Division Operator

**`Python 2.8`** **`from __future__ import absolute_import`** Imports: Multi-Line and Absolute/Relative

**`Python 2.7`** **`from __future__ import with_statement`** “with” Statement

**`Python 2.6`** **`from __future__ import print_function`** Make `print` a function

**`Python 3.0`** **`from __future__ import unicode_literals`** Unicode literals in Python 3000

**`Python 3.0`** **`from __future__ import stop_iteration`** Stop iteration handling inside generators

**`Python 3.0`** **`from __future__ import annotations`** Postponed evaluation of annotations

`from __future__ import annotations` was previously scheduled to become mandatory in Python 3.10, but the

Python Steering Council twice decided to delay the change ([announcement for Python 3.10](https://mail.python.org/archives/list/python-dev@python.org/message/CLVXXPQ2T2LQ5MP2Y53VVQFCXYWQJHKZ/) [https://mail.python.org/archives/list/python-dev@python.org/message/CLVXXPQ2T2LQ5MP2Y53VVQFCXYWQJHKZ/]; [announcement for Python 3.11](https://mail.python.org/archives/list/python-dev@python.org/message/VIZEBX5EYMSYIJNDBF6DMUMZOCWHARSO/) [https://mail.python.org/archives/list/python-dev@python.org/message/VIZEBX5EYMSYIJNDBF6DMUMZOCWHARSO/]). No final decision has been made yet. See also [PEP 563](https://peps.python.org/pep-0563/) [https://peps.python.org/pep-0563/] and [PEP 649](https://peps.python.org/pep-0649/) [https://peps.python.org/pep-0649/].

How the compiler treats future imports.

# gc — Garbage Collector interface

---

This module provides an interface to the optional garbage collector. It provides the ability to disable the collector, tune the collection frequency, and set debugging options. It also provides access to unreachable objects that the collector found but cannot free. Since the collector supplements the reference counting already used in Python, you can disable the collector if you are sure your program does not create reference cycles. Automatic collection can be disabled by calling `gc.disable()`. To debug a leaking program call `gc.set_debug(gc.DEBUG_LEAK)`. Notice that this includes `gc.DEBUG_SAVEALL`, causing garbage-collected objects to be saved in `gc.garbage` for inspection.

The `gc` module provides the following functions:

`gc.enable()`

Enable automatic garbage collection.

`gc.disable()`

Disable automatic garbage collection.

`gc.isenabled()`

Return `True` if automatic collection is enabled.

`gc.collect(generation=2)`

With no arguments, run a full collection. The optional argument *generation* may be an integer specifying which generation to collect (from 0 to 2). A `ValueError` is raised if the generation number is invalid. The number of unreachable objects found is returned.

The free lists maintained for a number of built-in types are cleared whenever a full collection or collection of the highest generation (2) is run. Not all items in some free lists may be freed due to the particular implementation, in particular `float`.

The effect of calling `gc.collect()` while the interpreter is already performing a collection is undefined.

### `gc.set_debug(flags)`

Set the garbage collection debugging flags. Debugging information will be written to `sys.stderr`. See below for a list of debugging flags which can be combined using bit operations to control debugging.

### `gc.get_debug()`

Return the debugging flags currently set.

### `gc.get_objects(generation=None)`

Returns a list of all objects tracked by the collector, excluding the list returned. If *generation* is not `None`, return only the objects tracked by the collector that are in that generation.

*Changed in version 3.8:* New *generation* parameter.

Raises an [auditing event](#) `gc.get_objects` with argument *generation*.

### `gc.get_stats()`

Return a list of three per-generation dictionaries containing collection statistics since interpreter start. The number of keys may change in the future, but currently each dictionary will contain the following items:

- `collections` is the number of times this generation was collected;
- `collected` is the total number of objects collected inside this generation;

- `uncollectable` is the total number of objects which were found to be uncollectable (and were therefore moved to the `garbage` list) inside this generation.

*New in version 3.4.*

```
gc.set_threshold(threshold0[, threshold1[, threshold2]])
```

Set the garbage collection thresholds (the collection frequency). Setting `threshold0` to zero disables collection.

The GC classifies objects into three generations depending on how many collection sweeps they have survived. New objects are placed in the youngest generation (generation 0). If an object survives a collection it is moved into the next older generation. Since generation 2 is the oldest generation, objects in that generation remain there after a collection. In order to decide when to run, the collector keeps track of the number object allocations and deallocations since the last collection. When the number of allocations minus the number of deallocations exceeds `threshold0`, collection starts. Initially only generation 0 is examined. If generation 0 has been examined more than `threshold1` times since generation 1 has been examined, then generation 1 is examined as well. With the third generation, things are a bit more complicated, see [Collecting the oldest generation](https://devguide.python.org/garbage_collector/#collecting-the-oldest-generation) [https://devguide.python.org/garbage\_collector/#collecting-the-oldest-generation] for more information.

```
gc.get_count()
```

Return the current collection counts as a tuple of `(count0, count1, count2)`.

```
gc.get_threshold()
```

Return the current collection thresholds as a tuple of `(threshold0, threshold1, threshold2)`.

```
gc.get_referrers(*objs)
```

Return the list of objects that directly refer to any of `objs`.

This function will only locate those containers which support garbage collection; extension types which do refer to other objects but do not support garbage collection will not be found.

Note that objects which have already been dereferenced, but which live in cycles and have not yet been collected by the garbage collector can be listed among the resulting referencers. To get only currently live objects, call `collect()` before calling `get_referencers()`.

### Warning

Care must be taken when using objects returned by `get_referencers()` because some of them could still be under construction and hence in a temporarily invalid state. Avoid using `get_referencers()` for any purpose other than debugging.

Raises an [auditing event](#) `gc.get_referencers` with argument `objs`.

### `gc.get_referents(*objs)`

Return a list of objects directly referred to by any of the arguments. The referents returned are those objects visited by the arguments' C-level `tp_traverse` methods (if any), and may not be all objects actually directly reachable.

`tp_traverse` methods are supported only by objects that support garbage collection, and are only required to visit objects that may be involved in a cycle. So, for example, if an integer is directly reachable from an argument, that integer object may or may not appear in the result list.

Raises an [auditing event](#) `gc.get_referents` with argument `objs`.

### `gc.is_tracked(obj)`

Returns `True` if the object is currently tracked by the garbage collector, `False` otherwise. As a general rule,

instances of atomic types aren't tracked and instances of non-atomic types (containers, user-defined objects...) are. However, some type-specific optimizations can be present in order to suppress the garbage collector footprint of simple instances (e.g. dicts containing only atomic keys and values):

```
>>> gc.is_tracked(0)
False
>>> gc.is_tracked("a")
False
>>> gc.is_tracked([])
True
>>> gc.is_tracked({})
False
>>> gc.is_tracked({"a": 1})
False
>>> gc.is_tracked({"a": []})
True
```

*New in version 3.1.*

`gc.is_finalized(obj)`

Returns `True` if the given object has been finalized by the garbage collector, `False` otherwise.

```
>>> x = None
>>> class Lazarus:
...     def __del__(self):
...         global x
...         x = self
...
>>> lazarus = Lazarus()
>>> gc.is_finalized(lazarus)
False
>>> del lazarus
>>> gc.is_finalized(x)
True
```

*New in version 3.9.*

## `gc.freeze()`

Freeze all the objects tracked by the garbage collector; move them to a permanent generation and ignore them in all the future collections.

If a process will `fork()` without `exec()`, avoiding unnecessary copy-on-write in child processes will maximize memory sharing and reduce overall memory usage. This requires both avoiding creation of freed “holes” in memory pages in the parent process and ensuring that GC collections in child processes won’t touch the `gc_refs` counter of long-lived objects originating in the parent process. To accomplish both, call `gc.disable()` early in the parent process, `gc.freeze()` right before `fork()`, and `gc.enable()` early in child processes.

*New in version 3.7.*

## `gc.unfreeze()`

Unfreeze the objects in the permanent generation, put them back into the oldest generation.

*New in version 3.7.*

## `gc.get_freeze_count()`

Return the number of objects in the permanent generation.

*New in version 3.7.*

The following variables are provided for read-only access (you can mutate the values but should not rebind them):

## `gc.garbage`

A list of objects which the collector found to be unreachable but could not be freed (uncollectable objects). Starting with Python 3.4, this list should be empty most of the time, except when using instances of C extension types with a non-NULL `tp_del` slot.

If `DEBUG_SAVEALL` is set, then all unreachable objects will be added to this list rather than freed.

*Changed in version 3.2:* If this list is non-empty at [interpreter shutdown](#), a `ResourceWarning` is emitted, which is silent by default. If `DEBUG_UNCOLLECTABLE` is set, in addition all uncollectable objects are printed.

*Changed in version 3.4:* Following [PEP 442](https://peps.python.org/pep-0442/) [https://peps.python.org/pep-0442/], objects with a `__del__()` method don't end up in `gc.garbage` anymore.

## `gc.callbacks`

A list of callbacks that will be invoked by the garbage collector before and after collection. The callbacks will be called with two arguments, *phase* and *info*.

*phase* can be one of two values:

“start”: The garbage collection is about to start.

“stop”: The garbage collection has finished.

*info* is a dict providing more information for the callback. The following keys are currently defined:

“generation”: The oldest generation being collected.

“collected”: When *phase* is “stop”, the number of objects successfully collected.

“uncollectable”: When *phase* is “stop”, the number of objects that could not be collected and were put in `garbage`.

Applications can add their own callbacks to this list. The primary use cases are:

Gathering statistics about garbage collection,

such as how often various generations are collected, and how long the collection takes.

Allowing applications to identify and clear their own uncollectable types when they appear in [garbage](#).

*New in version 3.3.*

The following constants are provided for use with [set\\_debug\(\)](#):

`gc.DEBUG_STATS`

Print statistics during collection. This information can be useful when tuning the collection frequency.

`gc.DEBUG_COLLECTABLE`

Print information on collectable objects found.

`gc.DEBUG_UNCOLLECTABLE`

Print information of uncollectable objects found (objects which are not reachable but cannot be freed by the collector). These objects will be added to the [garbage](#) list.

*Changed in version 3.2:* Also print the contents of the [garbage](#) list at [interpreter shutdown](#), if it isn't empty.

`gc.DEBUG_SAVEALL`

When set, all unreachable objects found will be appended to *garbage* rather than being freed. This can be useful for debugging a leaking program.

`gc.DEBUG_LEAK`

The debugging flags necessary for the collector to print information about a leaking program (equal to

`DEBUG_COLLECTABLE | DEBUG_UNCOLLECTABLE |  
DEBUG_SAVEALL`).

# inspect — Inspect live objects

**Source code:** [Lib/inspect.py](#) [<https://github.com/python/cpython/tree/3.12/Lib/inspect.py>]

---

The `inspect` module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module: type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.

## Types and members

The `getmembers()` function retrieves the members of an object such as a class or module. The functions whose names begin with “is” are mainly provided as convenient choices for the second argument to `getmembers()`. They also help you determine when you can expect to find the following special attributes (see [Import-related module attributes](#) for module attributes):

### Type description

Type	Description
<code>class</code>	documentation string
<code>name</code>	with which this class was defined
<code>qualifiedname</code>	
<code>module</code>	of module in which this class was defined
<code>doc</code>	documentation string
<code>name</code>	with which this method was defined
<code>qualifiedname</code>	
<code>function</code>	object containing implementation of method

`self` instance to which this method is bound, or `None`  
`__module__` module in which this method was defined  
`__doc__` documentation string  
`__name__` with which this function was defined  
`__qualname__`  
`code` object containing compiled function [bytecode](#)  
`tuple` of any default values for positional or keyword parameters  
`map` of default values for keyword-only parameters  
`global` namespace in which this function was defined  
`builtins` namespace  
`__annotations__` mapping of parameter names to annotations; "return" key is reserved for return annotations.  
`__module__` module in which this function was defined  
`__frame__` object at this level  
`__index__` of last attempted instruction in bytecode  
`__current__` line number in Python source code  
`__text__` traceback object (called by this level)  
`__frame__` outer frame object (this frame's caller)  
`__builtins__` namespace seen by this frame  
`code` object being executed in this frame  
`global` namespace seen by this frame  
`__index__` of last attempted instruction in bytecode  
`__current__` line number in Python source code  
`local` namespace seen by this frame  
`__trace__` function for this frame, or `None`  
`__code__` of arguments (not including keyword only arguments, \* or \*\* args)  
`__code__` of raw compiled bytecode  
`__code__` of frames of cell variables (referenced by containing scopes)  
`__code__` of constants used in the bytecode  
`__file__` file in which this code object was created  
`__firstlineno__` first line in Python source code  
`__flags__` of `CO_*` flags, read more [here](#)  
`__enclosed__` mapping of line numbers to bytecode indices  
`__free__` of names of free variables (referenced via a function's closure)  
`__posonlyargs__` of positional only arguments  
`__kwonlyargs__` of keyword only arguments (not including \*\* arg)  
`__name__` with which this code object was defined  
`__qualname__` fully qualified name with which this code object was defined

`top_level_names` names other than arguments and function locals

`num_locals` number of local variables

`virtual_size` virtual machine stack space required

`top_level_names` names of arguments and local variables

`generator`

`qualified_name`

`giframe`

`is_running` generator running?

`code`

`obj` object being iterated by `yield from`, or `None`

`name`

`qualified_name`

`obj` object being awaited on, or `None`

`fiframe`

`is_running` coroutine running?

`code`

`cr_origin` routine was created, or `None`. See

[`sys.set\_coroutine\_origin\_tracking\_depth\(\)`](#)

`doc` documentation string

`original_name` of this function or method

`qualified_name`

`instance` to which a method is bound, or `None`

*Changed in version 3.5:* Add `__qualname__` and `gi_yieldfrom` attributes to generators.

The `__name__` attribute of generators is now set from the function name, instead of the code name, and it can now be modified.

*Changed in version 3.7:* Add `cr_origin` attribute to coroutines.

*Changed in version 3.10:* Add `__builtins__` attribute to functions.

`inspect.getmembers(object[, predicate])`

Return all the members of an object in a list of `(name, value)` pairs sorted by name. If the optional *predicate* argument—which will be called with the `value` object of each member—is supplied, only members for which the predicate returns a true value are included.

## Note

`getmembers()` will only return class attributes defined in the metaclass when the argument is a class and those attributes have been listed in the metaclass' custom `__dir__()`.

`inspect.getmembers_static(object[, predicate])`

Return all the members of an object in a list of (name, value) pairs sorted by name without triggering dynamic lookup via the descriptor protocol, `__getattr__` or `__getattribute__`. Optionally, only return members that satisfy a given predicate.

## Note

`getmembers_static()` may not be able to retrieve all members that `getmembers` can fetch (like dynamically created attributes) and may find members that `getmembers` can't (like descriptors that raise `AttributeError`). It can also return descriptor objects instead of instance members in some cases.

*New in version 3.11.*

`inspect.getmodulename(path)`

Return the name of the module named by the file *path*, without including the names of enclosing packages. The file extension is checked against all of the entries in `importlib.machinery.all_suffixes()`. If it matches, the final path component is returned with the extension removed. Otherwise, `None` is returned.

Note that this function *only* returns a meaningful name for actual Python modules - paths that potentially refer to Python packages will still return `None`.

*Changed in version 3.3:* The function is based directly on

`importlib.`

`inspect.ismodule(object)`

Return `True` if the object is a module.

`inspect.isclass(object)`

Return `True` if the object is a class, whether built-in or created in Python code.

`inspect.ismethod(object)`

Return `True` if the object is a bound method written in Python.

`inspect.isfunction(object)`

Return `True` if the object is a Python function, which includes functions created by a `lambda` expression.

`inspect.isgeneratorfunction(object)`

Return `True` if the object is a Python generator function.

*Changed in version 3.8:* Functions wrapped in `functools.partial()` now return `True` if the wrapped function is a Python generator function.

`inspect.isgenerator(object)`

Return `True` if the object is a generator.

`inspect.iscoroutinefunction(object)`

Return `True` if the object is a `coroutine function` (a function defined with an `async def` syntax), a `functools.partial()` wrapping a `coroutine function`, or a sync function marked with `markcoroutinefunction()`.

*New in version 3.5.*

*Changed in version 3.8:* Functions wrapped in `functools.partial()` now return `True` if the wrapped

function is a [coroutine function](#).

*Changed in version 3.12:* Sync functions marked with [markcoroutinefunction\(\)](#) now return `True`.

`inspect.markcoroutinefunction(func)`

Decorator to mark a callable as a [coroutine function](#) if it would not otherwise be detected by [is\\_coroutine\\_function\(\)](#).

This may be of use for sync functions that return a [coroutine](#), if the function is passed to an API that requires [is\\_coroutine\\_function\(\)](#).

When possible, using an [async def](#) function is preferred. Also acceptable is calling the function and testing the return with [is\\_coroutine\(\)](#).

*New in version 3.12.*

`inspect.iscoroutine(object)`

Return `True` if the object is a [coroutine](#) created by an [async def](#) function.

*New in version 3.5.*

`inspect.isawaitable(object)`

Return `True` if the object can be used in [await](#) expression.

Can also be used to distinguish generator-based coroutines from regular generators:

```
def gen():
    yield
@types.coroutine
def gen_coro():
    yield

assert not isawaitable(gen())
```

```
assert isawaitable(gen_coro())
```

*New in version 3.5.*

`inspect.isasyncgenfunction(object)`

Return `True` if the object is an [asynchronous generator](#) function, for example:

```
>>> async def agen():
...     yield 1
...
>>> inspect.isasyncgenfunction(agen)
True
```

*New in version 3.6.*

*Changed in version 3.8:* Functions wrapped in [functools.partial\(\)](#) now return `True` if the wrapped function is a [asynchronous generator](#) function.

`inspect.isasyncgen(object)`

Return `True` if the object is an [asynchronous generator iterator](#) created by an [asynchronous generator](#) function.

*New in version 3.6.*

`inspect.istraceback(object)`

Return `True` if the object is a traceback.

`inspect.isframe(object)`

Return `True` if the object is a frame.

`inspect.iscode(object)`

Return `True` if the object is a code.

`inspect.isbuiltin(object)`

Return `True` if the object is a built-in function or a bound

built-in method.

`inspect.ismethodwrapper(object)`

Return `True` if the type of object is a `MethodWrapperType`.

These are instances of `MethodWrapperType`, such as `__str__()`, `__eq__()` and `__repr__()`.

*New in version 3.11.*

`inspect.isroutine(object)`

Return `True` if the object is a user-defined or built-in function or method.

`inspect.isabstract(object)`

Return `True` if the object is an abstract base class.

`inspect.ismethoddescriptor(object)`

Return `True` if the object is a method descriptor, but not if `ismethod()`, `isclass()`, `isfunction()` or `isbuiltin()` are true.

This, for example, is true of `int.__add__`. An object passing this test has a `__get__()` method but not a `__set__()` method, but beyond that the set of attributes varies. A `__name__` attribute is usually sensible, and `__doc__` often is.

Methods implemented via descriptors that also pass one of the other tests return `False` from the `ismethoddescriptor()` test, simply because the other tests promise more – you can, e.g., count on having the `__func__` attribute (etc) when an object passes `ismethod()`.

`inspect.isdatadescriptor(object)`

Return `True` if the object is a data descriptor.

Data descriptors have a `__set__` or a `__delete__` method. Examples are properties (defined in Python), getsets, and members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have `__name__` and `__doc__` attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

`inspect.isgetsetdescriptor(object)`

Return `True` if the object is a getset descriptor.

**CPython implementation detail:** getsets are attributes defined in extension modules via `PyGetSetDef` structures. For Python implementations without such types, this method will always return `False`.

`inspect.ismemberdescriptor(object)`

Return `True` if the object is a member descriptor.

**CPython implementation detail:** Member descriptors are attributes defined in extension modules via `PyMemberDef` structures. For Python implementations without such types, this method will always return `False`.

## Retrieving source code

`inspect.getdoc(object)`

Get the documentation string for an object, cleaned up with `cleandoc()`. If the documentation string for an object is not provided and the object is a class, a method, a property or a descriptor, retrieve the documentation string from the inheritance hierarchy. Return `None` if the documentation string is invalid or missing.

*Changed in version 3.5:* Documentation strings are now inherited if not overridden.

`inspect.getcomments(object)`

Return in a single string any lines of comments immediately preceding the object's source code (for a class, function, or method), or at the top of the Python source file (if the object is a module). If the object's source code is unavailable, return `None`. This could happen if the object has been defined in C or the interactive shell.

`inspect.getfile(object)`

Return the name of the (text or binary) file in which an object was defined. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getmodule(object)`

Try to guess which module an object was defined in. Return `None` if the module cannot be determined.

`inspect.getsourcefile(object)`

Return the name of the Python source file in which an object was defined or `None` if no way can be identified to get the source. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getsourcelines(object)`

Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was found. An `OSError` is raised if the source code cannot be retrieved. A `TypeError` is raised if the object is a built-in module, class, or function.

*Changed in version 3.3:* `OSError` is raised instead of `IOError`, now an alias of the former.

`inspect.getsource(object)`

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An **OSError** is raised if the source code cannot be retrieved. A **TypeError** is raised if the object is a built-in module, class, or function.

*Changed in version 3.3:* **OSError** is raised instead of **IOError**, now an alias of the former.

`inspect.cleandoc(doc)`

Clean up indentation from docstrings that are indented to line up with blocks of code.

All leading whitespace is removed from the first line. Any leading whitespace that can be uniformly removed from the second line onwards is removed. Empty lines at the beginning and end are subsequently removed. Also, all tabs are expanded to spaces.

## Introspecting callables with the Signature object

*New in version 3.3.*

The Signature object represents the call signature of a callable object and its return annotation. To retrieve a Signature object, use the **signature()** function.

`inspect.signature(callable, *, follow_wrapped=True, globals=None, locals=None, eval_str=False)`

Return a **Signature** object for the given callable:

```
>>> from inspect import signature
>>> def foo(a, *, b:int, **kwargs):
...     pass

>>> sig = signature(foo)
```

```
>>> str(sig)
'(a, *, b:int, **kwargs)'

>>> str(sig.parameters['b'])
'b:int'

>>> sig.parameters['b'].annotation
<class 'int'>
```

Accepts a wide range of Python callables, from plain functions and classes to `functools.partial()` objects.

For objects defined in modules using stringized annotations (from `__future__` import `annotations`), `signature()` will attempt to automatically un-stringize the annotations using `inspect.get_annotations()`. The `global`, `locals`, and `eval_str` parameters are passed into `inspect.get_annotations()` when resolving the annotations; see the documentation for `inspect.get_annotations()` for instructions on how to use these parameters.

Raises `ValueError` if no signature can be provided, and `TypeError` if that type of object is not supported. Also, if the annotations are stringized, and `eval_str` is not `false`, the `eval()` call(s) to un-stringize the annotations could potentially raise any kind of exception.

A slash(/) in the signature of a function denotes that the parameters prior to it are positional-only. For more info, see [the FAQ entry on positional-only parameters](#).

*New in version 3.5:* `follow_wrapped` parameter. Pass `False` to get a signature of `callable` specifically (`callable.__wrapped__` will not be used to unwrap decorated callables.)

*New in version 3.10:* `globals`, `locals`, and `eval_str` parameters.

## Note

Some callables may not be introspectable in certain implementations of Python. For example, in CPython, some built-in functions defined in C provide no metadata about their arguments.

```
class inspect.Signature(parameters=None, *,
return_annotation=Signature.empty)
```

A Signature object represents the call signature of a function and its return annotation. For each parameter accepted by the function it stores a [Parameter](#) object in its [parameters](#) collection.

The optional *parameters* argument is a sequence of [Parameter](#) objects, which is validated to check that there are no parameters with duplicate names, and that the parameters are in the right order, i.e. positional-only first, then positional-or-keyword, and that parameters with defaults follow parameters without defaults.

The optional *return\_annotation* argument, can be an arbitrary Python object, is the “return” annotation of the callable.

Signature objects are *immutable*. Use [Signature.replace\(\)](#) to make a modified copy.

*Changed in version 3.5:* Signature objects are picklable and [hashable](#).

### empty

A special class-level marker to specify absence of a return annotation.

### parameters

An ordered mapping of parameters’ names to the corresponding [Parameter](#) objects. Parameters appear in strict definition order, including keyword-only parameters.

*Changed in version 3.7:* Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

`return_annotation`

The “return” annotation for the callable. If the callable has no “return” annotation, this attribute is set to `Signature.empty`.

`bind(*args, **kwargs)`

Create a mapping from positional and keyword arguments to parameters. Returns `BoundArguments` if `*args` and `**kwargs` match the signature, or raises a `TypeError`.

`bind_partial(*args, **kwargs)`

Works the same way as `Signature.bind()`, but allows the omission of some required arguments (mimics `functools.partial()` behavior.) Returns `BoundArguments`, or raises a `TypeError` if the passed arguments do not match the signature.

`replace(*[, parameters][, return_annotation])`

Create a new Signature instance based on the instance `replace()` was invoked on. It is possible to pass different `parameters` and/or `return_annotation` to override the corresponding properties of the base signature. To remove `return_annotation` from the copied Signature, pass in `Signature.empty`.

```
>>> def test(a, b):
...     pass
...
>>> sig = signature(test)
>>> new_sig = sig.replace(return_annotation="new")
>>> str(new_sig)
```

```
"(a, b) -> 'new return anno'"
```

*classmethod* `from_callable(obj, *, follow_wrapped=True, globalns=None, localns=None)`

Return a **Signature** (or its subclass) object for a given callable `obj`. Pass `follow_wrapped=False` to get a signature of `obj` without unwrapping its `__wrapped__` chain. `globalns` and `localns` will be used as the namespaces when resolving annotations.

This method simplifies subclassing of **Signature**:

```
class MySignature(Signature):  
    pass  
sig = MySignature.from_callable(min)  
assert isinstance(sig, MySignature)
```

*New in version 3.5.*

*New in version 3.10:* `globalns` and `localns` parameters.

*class* `inspect.Parameter(name, kind, *, default=Parameter.empty, annotation=Parameter.empty)`

Parameter objects are *immutable*. Instead of modifying a Parameter object, you can use **`Parameter.replace()`** to create a modified copy.

*Changed in version 3.5:* Parameter objects are picklable and **hashable**.

**empty**

A special class-level marker to specify absence of default values and annotations.

**name**

The name of the parameter as a string. The name must be a valid Python identifier.

**CPython implementation detail:** CPython generates implicit parameter names of the form `._0` on the code objects used to implement comprehensions and generator expressions.

*Changed in version 3.6:* These parameter names are exposed by this module as names like `implicit0`.

## default

The default value for the parameter. If the parameter has no default value, this attribute is set to `Parameter.empty`.

## annotation

The annotation for the parameter. If the parameter has no annotation, this attribute is set to `Parameter.empty`.

## kind

Describes how argument values are bound to the parameter. The possible values are accessible via `Parameter` (like `Parameter.KEYWORD_ONLY`), and support comparison and ordering, in the following order:

### Meaning

---

**POSITIONAL\_ONLY** Applied as a positional argument.

Positional only parameters are those which appear before a `/` entry (if present) in a Python function definition.

---

**POSITIONAL\_OR\_KEYWORD** Applied as either a keyword or

positional argument (this is the standard binding behaviour for functions implemented in Python.)

---

**VAR\_POSITIONAL** Applied to final arguments that aren't bound to any other parameter. This corresponds to a `*args` parameter in a Python function definition.

---

**KEYWORD\_ONLY** Applied as a keyword argument.

Keyword only parameters are those which appear after a `*` or `*args` entry in a Python function

---

definition.

---

**KEYWORD\_ONLY** Keyword arguments that aren't bound to any other parameter. This corresponds to a `**kwargs` parameter in a Python function definition.

---

Example: print all keyword-only arguments without default values:

```
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     if (param.kind == param.KEYWORD_ONLY and
...         param.default is param.empty):
...         print('Parameter:', param)
Parameter: c
```

`kind.description`

Describes an enum value of `Parameter.kind`.

*New in version 3.8.*

Example: print all descriptions of arguments:

```
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     print(param.kind.description)
positional or keyword
positional or keyword
keyword-only
keyword-only
```

`replace(*[, name][, kind][, default][, annotation])`

Create a new `Parameter` instance based on the instance

replaced was invoked on. To override a `Parameter` attribute, pass the corresponding argument. To remove a default value or/and an annotation from a `Parameter`, pass `Parameter.empty`.

```
>>> from inspect import Parameter
>>> param = Parameter('foo', Parameter.KEYWORD_ONLY)
>>> str(param)
'foo=42'

>>> str(param.replace()) # Will create a shallow copy
'foo=42'

>>> str(param.replace(default=Parameter.empty,
                        "foo:'spam'"))
```

*Changed in version 3.4:* In Python 3.3 `Parameter` objects were allowed to have `name` set to `None` if their `kind` was set to `POSITIONAL_ONLY`. This is no longer permitted.

`class inspect.BoundArguments`

Result of a `Signature.bind()` or `Signature.bind_partial()` call. Holds the mapping of arguments to the function's parameters.

arguments

A mutable mapping of parameters' names to arguments' values. Contains only explicitly bound arguments. Changes in `arguments` will reflect in `args` and `kwargs`.

Should be used in conjunction with `Signature.parameters` for any argument processing purposes.

### Note

Arguments for which `Signature.bind()` or `Signature.bind_partial()` relied on a default value are skipped. However, if needed, use

`BoundArguments.apply_defaults()` to add them.

*Changed in version 3.9:* `arguments` is now of type `dict`. Formerly, it was of type `collections.OrderedDict`.

`args`

A tuple of positional arguments values. Dynamically computed from the `arguments` attribute.

`kwargs`

A dict of keyword arguments values. Dynamically computed from the `arguments` attribute.

`signature`

A reference to the parent `Signature` object.

`apply_defaults()`

Set default values for missing arguments.

For variable-positional arguments (`*args`) the default is an empty tuple.

For variable-keyword arguments (`**kwargs`) the default is an empty dict.

```
>>> def foo(a, b='ham', *args): pass
>>> ba = inspect.signature(foo).bind('spam')
>>> ba.apply_defaults()
>>> ba.arguments
{'a': 'spam', 'b': 'ham', 'args': ()}
```

*New in version 3.5.*

The `args` and `kwargs` properties can be used to invoke functions:

```
def test(a, *, b):  
    ...  
  
sig = signature(test)  
ba = sig.bind(10, b=20)  
test(*ba.args, **ba.kwargs)
```

**See also**

**PEP 362** [<https://peps.python.org/pep-0362/>] - **Function Signature Object**.

The detailed specification, implementation details and examples.

## Classes and functions

`inspect.getclasstree(classes, unique=False)`

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple containing a class and a tuple of its base classes. If the *unique* argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

`inspect.getfullargspec(func)`

Get the names and default values of a Python function's parameters. A [named tuple](#) is returned:

```
FullArgSpec(args, varargs, varkw, defaults,  
            kwonlyargs, kwonlydefaults, annotations)
```

*args* is a list of the positional parameter names. *varargs* is the name of the `*` parameter or `None` if arbitrary positional arguments are not accepted. *varkw* is the name of the `**` parameter or `None` if arbitrary keyword arguments are not

accepted. *defaults* is an *n*-tuple of default argument values corresponding to the last *n* positional parameters, or `None` if there are no such defaults defined. *kwonlyargs* is a list of keyword-only parameter names in declaration order. *kwonlydefaults* is a dictionary mapping parameter names from *kwonlyargs* to the default values used if no argument is supplied. *annotations* is a dictionary mapping parameter names to annotations. The special key `"return"` is used to report the function return value annotation (if any).

Note that `signature()` and `Signature Object` provide the recommended API for callable introspection, and support additional behaviours (like positional-only arguments) that are sometimes encountered in extension module APIs. This function is retained primarily for use in code that needs to maintain compatibility with the Python 2 `inspect` module API.

*Changed in version 3.4:* This function is now based on `signature()`, but still ignores `__wrapped__` attributes and includes the already bound first parameter in the signature output for bound methods.

*Changed in version 3.6:* This method was previously documented as deprecated in favour of `signature()` in Python 3.5, but that decision has been reversed in order to restore a clearly supported standard interface for single-source Python 2/3 code migrating away from the legacy `getargspec()` API.

*Changed in version 3.7:* Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

`inspect.getargvalues(frame)`

Get information about arguments passed into a particular frame. A `named tuple` `ArgInfo(args, varargs, keywords, locals)` is returned. *args* is a list of the argument names. *varargs* and *keywords* are the names of the

*\** and *\*\** arguments or *None*. *locals* is the locals dictionary of the given frame.

### Note

This function was inadvertently marked as deprecated in Python 3.5.

`inspect.formatargvalues(args[, varargs, varkw, locals, formatarg, formatvarargs, formatvarkw, formatvalue])`

Format a pretty argument spec from the four values returned by `getargvalues()`. The *format\** arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

### Note

This function was inadvertently marked as deprecated in Python 3.5.

`inspect.getmro(cls)`

Return a tuple of class *cls*'s base classes, including *cls*, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on *cls*'s type. Unless a very peculiar user-defined metatype is in use, *cls* will be the first element of the tuple.

`inspect.getcallargs(func, /, *args, **kwargs)`

Bind the *args* and *kwargs* to the argument names of the Python function or method *func*, as if it was called with them. For bound methods, bind also the first argument (typically named *self*) to the associated instance. A dict is returned, mapping the argument names (including the names of the *\** and *\*\** arguments, if any) to their values from *args* and *kwargs*. In case of invoking *func* incorrectly, i.e. whenever `func(*args, **kwargs)` would raise an exception because of incompatible

signature, an exception of the same type and the same or similar message is raised. For example:

```
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...     pass
...
>>> getcallargs(f, 1, 2, 3) == {'a': 1, 'named': {}}
True
>>> getcallargs(f, a=2, x=4) == {'a': 2, 'named': {}}
True
>>> getcallargs(f)
Traceback (most recent call last):
...
TypeError: f() missing 1 required positional argument
```

*New in version 3.2.*

*Deprecated since version 3.5:* Use [Signature.bind\(\)](#) and [Signature.bind\\_partial\(\)](#) instead.

`inspect.getclosurevars(func)`

Get the mapping of external name references in a Python function or method *func* to their current values. A [named tuple](#) `ClosureVars(nonlocals, globals, builtins, unbound)` is returned. *nonlocals* maps referenced names to lexical closure variables, *globals* to the function's module globals and *builtins* to the builtins visible from the function body. *unbound* is the set of names referenced in the function that could not be resolved at all given the current module globals and builtins.

[TypeError](#) is raised if *func* is not a Python function or method.

*New in version 3.3.*

`inspect.unwrap(func, *, stop=None)`

Get the object wrapped by *func*. It follows the chain of

`__wrapped__` attributes returning the last object in the chain.

`stop` is an optional callback accepting an object in the wrapper chain as its sole argument that allows the unwrapping to be terminated early if the callback returns a true value. If the callback never returns a true value, the last object in the chain is returned as usual. For example, `signature()` uses this to stop unwrapping if any object in the chain has a `__signature__` attribute defined.

`ValueError` is raised if a cycle is encountered.

*New in version 3.4.*

`inspect.get_annotations(obj, *, globals=None, locals=None, eval_str=False)`

Compute the annotations dict for an object.

`obj` may be a callable, class, or module. Passing in an object of any other type raises `TypeError`.

Returns a dict. `get_annotations()` returns a new dict every time it's called; calling it twice on the same object will return two different but equivalent dicts.

This function handles several details for you:

- If `eval_str` is true, values of type `str` will be un-stringized using `eval()`. This is intended for use with stringized annotations (`from __future__ import annotations`).
- If `obj` doesn't have an annotations dict, returns an empty dict. (Functions and methods always have an annotations dict; classes, modules, and other types of callables may not.)
- Ignores inherited annotations on classes. If a class doesn't have its own annotations dict, returns an empty dict.
- All accesses to object members and dict values are done

using `getattr()` and `dict.get()` for safety.

- Always, always, always returns a freshly created dict.

`eval_str` controls whether or not values of type `str` are replaced with the result of calling `eval()` on those values:

- If `eval_str` is true, `eval()` is called on values of type `str`. (Note that `get_annotations` doesn't catch exceptions; if `eval()` raises an exception, it will unwind the stack past the `get_annotations` call.)
- If `eval_str` is false (the default), values of type `str` are unchanged.

`globals` and `locals` are passed in to `eval()`; see the documentation for `eval()` for more information. If `globals` or `locals` is `None`, this function may replace that value with a context-specific default, contingent on `type(obj)`:

- If `obj` is a module, `globals` defaults to `obj.__dict__`.
- If `obj` is a class, `globals` defaults to `sys.modules[obj.__module__].__dict__` and `locals` defaults to the `obj` class namespace.
- If `obj` is a callable, `globals` defaults to `obj.__globals__`, although if `obj` is a wrapped function (using `functools.update_wrapper()`) it is first unwrapped.

Calling `get_annotations` is best practice for accessing the annotations dict of any object. See [Annotations Best Practices](#) for more information on annotations best practices.

*New in version 3.10.*

## The interpreter stack

Some of the following functions return `FrameInfo` objects. For backwards compatibility these objects allow tuple-like operations on all attributes except `positions`. This behavior is considered deprecated and may be removed in the future.

*class* inspect.FrameInfo

frame

The [frame object](#) that the record corresponds to.

filename

The file name associated with the code being executed by the frame this record corresponds to.

lineno

The line number of the current line associated with the code being executed by the frame this record corresponds to.

function

The function name that is being executed by the frame this record corresponds to.

code\_context

A list of lines of context from the source code that's being executed by the frame this record corresponds to.

index

The index of the current line being executed in the [code\\_context](#) list.

positions

A [dis.Positions](#) object containing the start line number, end line number, start column offset, and end column offset associated with the instruction being executed by the frame this record corresponds to.

*Changed in version 3.5:* Return a [named tuple](#) instead of a [tuple](#).

*Changed in version 3.11:* **FrameInfo** is now a class instance (that is backwards compatible with the previous [named tuple](#)).

*class inspect.Traceback*

filename

The file name associated with the code being executed by the frame this traceback corresponds to.

lineno

The line number of the current line associated with the code being executed by the frame this traceback corresponds to.

function

The function name that is being executed by the frame this traceback corresponds to.

code\_context

A list of lines of context from the source code that's being executed by the frame this traceback corresponds to.

index

The index of the current line being executed in the `code_context` list.

positions

A `dis.Positions` object containing the start line number, end line number, start column offset, and end column offset associated with the instruction being executed by the frame this traceback corresponds to.

*Changed in version 3.11:* **Traceback** is now a class instance (that is backwards compatible with the previous `named tuple`).

## Note

Keeping references to frame objects, as found in the first element

of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python's optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs.

Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a **finally** clause. This is also important if the cycle detector was disabled when Python was compiled or using **gc.disable()**. For example:

```
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
        del frame
```

If you want to keep the frame around (for example to print a traceback later), you can also break reference cycles by using the **frame.clear()** method.

The optional *context* argument supported by most of these functions specifies the number of lines of context to return, which are centered around the current line.

`inspect.getframeinfo(frame, context=1)`

Get information about a frame or traceback object. A **Traceback** object is returned.

*Changed in version 3.11:* A **Traceback** object is returned instead of a named tuple.

`inspect.getouterframes(frame, context=1)`

Get a list of **FrameInfo** objects for a frame and all outer

frames. These frames represent the calls that lead to the creation of *frame*. The first entry in the returned list represents *frame*; the last entry represents the outermost call on *frame*'s stack.

*Changed in version 3.5:* A list of [named tuples](#)

`FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

*Changed in version 3.11:* A list of [FrameInfo](#) objects is returned.

`inspect.getinnerframes(traceback, context=1)`

Get a list of [FrameInfo](#) objects for a traceback's frame and all inner frames. These frames represent calls made as a consequence of *frame*. The first entry in the list represents *traceback*; the last entry represents where the exception was raised.

*Changed in version 3.5:* A list of [named tuples](#)

`FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

*Changed in version 3.11:* A list of [FrameInfo](#) objects is returned.

`inspect.currentframe()`

Return the frame object for the caller's stack frame.

**CPython implementation detail:** This function relies on Python stack frame support in the interpreter, which isn't guaranteed to exist in all implementations of Python. If running in an implementation without Python stack frame support this function returns `None`.

`inspect.stack(context=1)`

Return a list of [FrameInfo](#) objects for the caller's stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.

*Changed in version 3.5:* A list of **named tuples**

`FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

*Changed in version 3.11:* A list of **FrameInfo** objects is returned.

```
inspect.trace(context=1)
```

Return a list of **FrameInfo** objects for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.

*Changed in version 3.5:* A list of **named tuples**

`FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

*Changed in version 3.11:* A list of **FrameInfo** objects is returned.

## Fetching attributes statically

Both **getattr()** and **hasattr()** can trigger code execution when fetching or checking for the existence of attributes.

Descriptors, like properties, will be invoked and **\_\_getattr\_\_()** and **\_\_getattribute\_\_()** may be called.

For cases where you want passive introspection, like documentation tools, this can be inconvenient. **getattr\_static()** has the same signature as **getattr()** but avoids executing code when it fetches attributes.

```
inspect.getattr_static(obj, attr, default=None)
```

Retrieve attributes without triggering dynamic lookup via the descriptor protocol, **\_\_getattr\_\_()** or **\_\_getattribute\_\_()**.

Note: this function may not be able to retrieve all attributes

that `getattr` can fetch (like dynamically created attributes) and may find attributes that `getattr` can't (like descriptors that raise `AttributeError`). It can also return descriptors objects instead of instance members.

If the instance `__dict__` is shadowed by another member (for example a property) then this function will be unable to find instance members.

*New in version 3.2.*

`getattr_static()` does not resolve descriptors, for example slot descriptors or getset descriptors on objects implemented in C. The descriptor object is returned instead of the underlying attribute.

You can handle these with code like the following. Note that for arbitrary getset descriptors invoking these may trigger code execution:

```
# example code for resolving the builtin descriptor types
class _foo:
    __slots__ = ['foo']

slot_descriptor = type(_foo.foo)
getset_descriptor = type(type(open(__file__)).name)
wrapper_descriptor = type(str.__dict__['__add__'])
descriptor_types = (slot_descriptor, getset_descriptor,
                    wrapper_descriptor)

result = getattr_static(some_object, 'foo')
if type(result) in descriptor_types:
    try:
        result = result.__get__()
    except AttributeError:
        # descriptors can raise AttributeError to
        # indicate there is no underlying value
        # in which case the descriptor itself will
        # have to do
        pass
```

# Current State of Generators, Coroutines, and Asynchronous Generators

When implementing coroutine schedulers and for other advanced uses of generators, it is useful to determine whether a generator is currently executing, is waiting to start or resume or execution, or has already terminated. `getgeneratorstate()` allows the current state of a generator to be determined easily.

`inspect.getgeneratorstate(generator)`

Get current state of a generator-iterator.

Possible states are:

- `GEN_CREATED`: Waiting to start execution.
- `GEN_RUNNING`: Currently being executed by the interpreter.
- `GEN_SUSPENDED`: Currently suspended at a yield expression.
- `GEN_CLOSED`: Execution has completed.

*New in version 3.2.*

`inspect.getcoroutinestate(coroutine)`

Get current state of a coroutine object. The function is intended to be used with coroutine objects created by `async def` functions, but will accept any coroutine-like object that has `cr_running` and `cr_frame` attributes.

Possible states are:

- `CORO_CREATED`: Waiting to start execution.
- `CORO_RUNNING`: Currently being executed by the interpreter.
- `CORO_SUSPENDED`: Currently suspended at an await expression.
- `CORO_CLOSED`: Execution has completed.

*New in version 3.5.*

`inspect.getasyncgenstate(agen)`

Get current state of an asynchronous generator object. The function is intended to be used with asynchronous iterator objects created by `async def` functions which use the `yield` statement, but will accept any asynchronous generator-like object that has `ag_running` and `ag_frame` attributes.

Possible states are:

- `AGEN_CREATED`: Waiting to start execution.
- `AGEN_RUNNING`: Currently being executed by the interpreter.
- `AGEN_SUSPENDED`: Currently suspended at a yield expression.
- `AGEN_CLOSED`: Execution has completed.

*New in version 3.12.*

The current internal state of the generator can also be queried. This is mostly useful for testing purposes, to ensure that internal state is being updated as expected:

`inspect.getgeneratorlocals(generator)`

Get the mapping of live local variables in *generator* to their current values. A dictionary is returned that maps from variable names to values. This is the equivalent of calling `locals()` in the body of the generator, and all the same caveats apply.

If *generator* is a `generator` with no currently associated frame, then an empty dictionary is returned. `TypeError` is raised if *generator* is not a Python generator object.

**CPython implementation detail:** This function relies on the generator exposing a Python stack frame for introspection, which isn't guaranteed to be the case in all implementations of Python. In such cases, this function will always return an empty dictionary.

*New in version 3.3.*

`inspect.getcoroutinelocals(coroutine)`

This function is analogous to `getgeneratorlocals()`, but works for coroutine objects created by `async def` functions.

*New in version 3.5.*

`inspect.getasyncgenlocals(agen)`

This function is analogous to `getgeneratorlocals()`, but works for asynchronous generator objects created by `async def` functions which use the `yield` statement.

*New in version 3.12.*

## Code Objects Bit Flags

Python code objects have a `co_flags` attribute, which is a bitmap of the following flags:

`inspect.CO_OPTIMIZED`

The code object is optimized, using fast locals.

`inspect.CO_NEWLOCALS`

If set, a new dict will be created for the frame's `f_locals` when the code object is executed.

`inspect.CO_VARARGS`

The code object has a variable positional parameter (`*args`-like).

`inspect.CO_VARKEYWORDS`

The code object has a variable keyword parameter (`**kwargs`-like).

`inspect.CO_NESTED`

The flag is set when the code object is a nested function.

#### `inspect.CO_GENERATOR`

The flag is set when the code object is a generator function, i.e. a generator object is returned when the code object is executed.

#### `inspect.CO_COROUTINE`

The flag is set when the code object is a coroutine function. When the code object is executed it returns a coroutine object. See [PEP 492](https://peps.python.org/pep-0492/) [https://peps.python.org/pep-0492/] for more details.

*New in version 3.5.*

#### `inspect.CO_ITERABLE_COROUTINE`

The flag is used to transform generators into generator-based coroutines. Generator objects with this flag can be used in `await` expression, and can `yield` from coroutine objects. See [PEP 492](https://peps.python.org/pep-0492/) [https://peps.python.org/pep-0492/] for more details.

*New in version 3.5.*

#### `inspect.CO_ASYNC_GENERATOR`

The flag is set when the code object is an asynchronous generator function. When the code object is executed it returns an asynchronous generator object. See [PEP 525](https://peps.python.org/pep-0525/) [https://peps.python.org/pep-0525/] for more details.

*New in version 3.6.*

### **Note**

The flags are specific to CPython, and may not be defined in other Python implementations. Furthermore, the flags are an implementation detail, and can be removed or deprecated in future Python releases. It's recommended to use public APIs from the `inspect` module for any introspection needs.

# Buffer flags

*class inspect.BufferFlags*

This is an [enum.IntFlag](#) that represents the flags that can be passed to the [\\_\\_buffer\\_\\_\(\)](#) method of objects implementing the [buffer protocol](#).

The meaning of the flags is explained at [Buffer request types](#).

## Command Line Interface

The `inspect` module also provides a basic introspection capability from the command line.

By default, accepts the name of a module and prints the source of that module. A class or function within the module can be printed instead by appended a colon and the qualified name of the target object.

`--details`

Print information about the specified object rather than the source code

# site — Site-specific configuration hook

**Source code:** [Lib/site.py](https://github.com/python/cpython/tree/3.12/Lib/site.py) [https://github.com/python/cpython/tree/3.12/Lib/site.py]

---

**This module is automatically imported during initialization.** The automatic import can be suppressed using the interpreter's **-S** option.

Importing this module will append site-specific paths to the module search path and add a few builtins, unless **-S** was used. In that case, this module can be safely imported with no automatic modifications to the module search path or additions to the builtins. To explicitly trigger the usual site-specific additions, call the **main()** function.

*Changed in version 3.3:* Importing the module used to trigger paths manipulation even when using **-S**.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses `sys.prefix` and `sys.exec_prefix`; empty heads are skipped. For the tail part, it uses the empty string and then `lib/site-packages` (on Windows) or `lib/pythonX.Y/site-packages` (on Unix and macOS). For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to `sys.path` and also inspects the newly added path for configuration files.

*Changed in version 3.5:* Support for the “site-python” directory has been removed.

If a file named “pyvenv.cfg” exists one directory above `sys.executable`, `sys.prefix` and `sys.exec_prefix` are set to that directory and it is also checked for site-packages (`sys.base_prefix`

and `sys.base_exec_prefix` will always be the “real” prefixes of the Python installation). If “`pyvenv.cfg`” (a bootstrap configuration file) contains the key “`include-system-site-packages`” set to anything other than “`true`” (case-insensitive), the system-level prefixes will not be searched for site-packages; otherwise they will.

A path configuration file is a file whose name has the form `name.pth` and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to `sys.path`. Non-existing items are never added to `sys.path`, and no check is made that the item refers to a directory rather than a file. No item is added to `sys.path` more than once. Blank lines and lines beginning with `#` are skipped. Lines starting with `import` (followed by space or tab) are executed.

### Note

An executable line in a `.pth` file is run at every Python startup, regardless of whether a particular module is actually going to be used. Its impact should thus be kept to a minimum. The primary intended purpose of executable lines is to make the corresponding module(s) importable (load 3rd-party import hooks, adjust **`PATH`** etc). Any other initialization is supposed to be done upon a module’s actual import, if and when it happens. Limiting a code chunk to a single line is a deliberate measure to discourage putting anything more complex here.

For example, suppose `sys.prefix` and `sys.exec_prefix` are set to `/usr/local`. The Python X.Y library is then installed in `/usr/local/lib/pythonX.Y`. Suppose this has a subdirectory `/usr/local/lib/pythonX.Y/site-packages` with three subsubdirectories, `foo`, `bar` and `spam`, and two path configuration files, `foo.pth` and `bar.pth`. Assume `foo.pth` contains the following:

```
# foo package configuration

foo
bar
bletch
```

and `bar.pth` contains:

```
# bar package configuration  
  
bar
```

Then the following version-specific directories are added to `sys.path`, in this order:

```
/usr/local/lib/pythonX.Y/site-packages/bar  
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that `bletch` is omitted because it doesn't exist; the `bar` directory precedes the `foo` directory because `bar.pth` comes alphabetically before `foo.pth`; and `spam` is omitted because it is not mentioned in either path configuration file.

## sitecustomize

After these path manipulations, an attempt is made to import a module named `sitecustomize`, which can perform arbitrary site-specific customizations. It is typically created by a system administrator in the site-packages directory. If this import fails with an `ImportError` or its subclass exception, and the exception's `name` attribute equals to `'sitecustomize'`, it is silently ignored. If Python is started without output streams available, as with `pythonw.exe` on Windows (which is used by default to start IDLE), attempted output from `sitecustomize` is ignored. Any other exception causes a silent and perhaps mysterious failure of the process.

## usercustomize

After this, an attempt is made to import a module named `usercustomize`, which can perform arbitrary user-specific customizations, if `ENABLE_USER_SITE` is true. This file is intended to be created in the user site-packages directory (see below), which is part of `sys.path` unless disabled by `-s`. If this import fails with an `ImportError` or its subclass exception, and

the exception's `name` attribute equals to `'usercustomize'`, it is silently ignored.

Note that for some non-Unix systems, `sys.prefix` and `sys.exec_prefix` are empty, and the path manipulations are skipped; however the import of `sitecustomize` and `usercustomize` is still attempted.

## Readline configuration

On systems that support `readline`, this module will also import and configure the `rlcompleter` module, if Python is started in `interactive mode` and without the `-S` option. The default behavior is enable tab-completion and to use `~/.python_history` as the history save file. To disable it, delete (or override) the `sys.__interactivehook__` attribute in your `sitecustomize` or `usercustomize` module or your `PYTHONSTARTUP` file.

*Changed in version 3.4:* Activation of `rlcompleter` and history was made automatic.

## Module contents

`site.PREFIXES`

A list of prefixes for site-packages directories.

`site.ENABLE_USER_SITE`

Flag showing the status of the user site-packages directory. True means that it is enabled and was added to `sys.path`. False means that it was disabled by user request (with `-s` or `PYTHONNOUSERSITE`). None means it was disabled for security reasons (mismatch between user or group id and effective id) or by an administrator.

`site.USER_SITE`

Path to the user site-packages for the running Python. Can be None if `getusersitepackages()` hasn't been called yet. Default value is `~/.local/lib/pythonX.Y/site-`

packages for UNIX and non-framework macOS builds, `~/Library/Python/X.Y/lib/python/site-packages` for macOS framework builds, and `%APPDATA%\Python\PythonXY\site-packages` on Windows. This directory is a site directory, which means that `.pth` files in it will be processed.

#### `site.USER_BASE`

Path to the base directory for the user site-packages. Can be `None` if `getuserbase()` hasn't been called yet. Default value is `~/local` for UNIX and macOS non-framework builds, `~/Library/Python/X.Y` for macOS framework builds, and `%APPDATA%\Python` for Windows. This value is used to compute the installation directories for scripts, data files, Python modules, etc. for the [user installation scheme](#). See also [PYTHONUSERBASE](#).

#### `site.main()`

Adds all the standard site-specific directories to the module search path. This function is called automatically when this module is imported, unless the Python interpreter was started with the `-S` flag.

*Changed in version 3.3:* This function used to be called unconditionally.

#### `site.addsitedir(sitedir, known_paths=None)`

Add a directory to `sys.path` and process its `.pth` files. Typically used in [sitecustomize](#) or [usercustomize](#) (see above).

#### `site.getsitepackages()`

Return a list containing all global site-packages directories.

*New in version 3.2.*

#### `site.getuserbase()`

Return the path of the user base directory, [USER\\_BASE](#). If it

is not initialized yet, this function will also set it, respecting **PYTHONUSERBASE**.

*New in version 3.2.*

`site.getusersitepackages()`

Return the path of the user-specific site-packages directory, **USER\_SITE**. If it is not initialized yet, this function will also set it, respecting **USER\_BASE**. To determine if the user-specific site-packages was added to `sys.path` **ENABLE\_USER\_SITE** should be used.

*New in version 3.2.*

## Command Line Interface

The **site** module also provides a way to get the user directories from the command line:

```
$ python -m site --user-site
/home/user/.local/lib/python3.11/site-packages
```

If it is called without arguments, it will print the contents of **sys.path** on the standard output, followed by the value of **USER\_BASE** and whether the directory exists, then the same thing for **USER\_SITE**, and finally the value of **ENABLE\_USER\_SITE**.

**--user-base**

Print the path to the user base directory.

**--user-site**

Print the path to the user site-packages directory.

If both options are given, user base and user site will be printed (always in this order), separated by **os.pathsep**.

If any option is given, the script will exit with one of these values: 0 if the user site-packages directory is enabled, 1 if it was disabled by the user, 2 if it is disabled for security reasons or by an

administrator, and a value greater than 2 if there is an error.

# Custom Python Interpreters

The modules described in this chapter allow writing interfaces similar to Python’s interactive interpreter. If you want a Python interpreter that supports some special feature in addition to the Python language, you should look at the [code](#) module. (The [codeop](#) module is lower-level, used to support compiling a possibly incomplete chunk of Python code.)

The full list of modules described in this chapter is:

- [code](#) — Interpreter base classes
  - [Interactive Interpreter Objects](#)
  - [Interactive Console Objects](#)
- [codeop](#) — Compile Python code

# code — Interpreter base classes

**Source code:** [Lib/code.py](https://github.com/python/cpython/tree/3.12/Lib/code.py) [https://github.com/python/cpython/tree/3.12/Lib/code.py]

---

The `code` module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

*class* `code.InteractiveInterpreter(locals=None)`

This class deals with parsing and interpreter state (the user's namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional *locals* argument specifies the dictionary in which code will be executed; it defaults to a newly created dictionary with key `'__name__'` set to `'__console__'` and key `'__doc__'` set to `None`.

*class* `code.InteractiveConsole(locals=None, filename='<console>')`

Closely emulate the behavior of the interactive Python interpreter. This class builds on [InteractiveInterpreter](#) and adds prompting using the familiar `sys.ps1` and `sys.ps2`, and input buffering.

`code.interact(banner=None, readfunc=None, local=None, exitmsg=None)`

Convenience function to run a read-eval-print loop. This creates a new instance of [InteractiveConsole](#) and sets *readfunc* to be used as the [InteractiveConsole.raw\\_input\(\)](#) method, if provided. If *local* is provided, it is passed to the [InteractiveConsole](#) constructor for use as the default namespace for the interpreter loop. The [interact\(\)](#)

method of the instance is then run with *banner* and *exitmsg* passed as the banner and exit message to use, if provided. The console object is discarded after use.

*Changed in version 3.6:* Added *exitmsg* parameter.

```
code.compile_command(source, filename='<input>',  
symbol='single')
```

This function is useful for programs that want to emulate Python's interpreter main loop (a.k.a. the read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function *almost* always makes the same decision as the real interpreter main loop.

*source* is the source string; *filename* is the optional filename from which source was read, defaulting to '*<input>*'; and *symbol* is the optional grammar start symbol, which should be 'single' (the default), 'eval' or 'exec'.

Returns a code object (the same as `compile(source, filename, symbol)`) if the command is complete and valid; `None` if the command is incomplete; raises **SyntaxError** if the command is complete and contains a syntax error, or raises **OverflowError** or **ValueError** if the command contains an invalid literal.

## Interactive Interpreter Objects

```
InteractiveInterpreter.runsource(source, filename='<input>',  
symbol='single')
```

Compile and run some source in the interpreter. Arguments are the same as for `compile_command()`; the default for *filename* is '*<input>*', and for *symbol* is 'single'. One of several things can happen:

- The input is incorrect; `compile_command()` raised an exception (**SyntaxError** or **OverflowError**). A

syntax traceback will be printed by calling the `showsyntaxerror()` method. `runsource()` returns `False`.

- The input is incomplete, and more input is required; `compile_command()` returned `None`. `runsource()` returns `True`.
- The input is complete; `compile_command()` returned a code object. The code is executed by calling the `runcode()` (which also handles run-time exceptions, except for `SystemExit`). `runsource()` returns `False`.

The return value can be used to decide whether to use `sys.ps1` or `sys.ps2` to prompt the next line.

### `InteractiveInterpreter.runcode(code)`

Execute a code object. When an exception occurs, `showtraceback()` is called to display a traceback. All exceptions are caught except `SystemExit`, which is allowed to propagate.

A note about `KeyboardInterrupt`: this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.

### `InteractiveInterpreter.showsyntaxerror(filename=None)`

Display the syntax error that just occurred. This does not display a stack trace because there isn't one for syntax errors. If *filename* is given, it is stuffed into the exception instead of the default filename provided by Python's parser, because it always uses `'<string>'` when reading from a string. The output is written by the `write()` method.

### `InteractiveInterpreter.showtraceback()`

Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the `write()` method.

*Changed in version 3.5:* The full chained traceback is displayed instead of just the primary traceback.

`InteractiveInterpreter.write(data)`

Write a string to the standard error stream (`sys.stderr`). Derived classes should override this to provide the appropriate output handling as needed.

## Interactive Console Objects

The `InteractiveConsole` class is a subclass of `InteractiveInterpreter`, and so offers all the methods of the interpreter objects as well as the following additions.

`InteractiveConsole.interact(banner=None, exitmsg=None)`

Closely emulate the interactive Python console. The optional *banner* argument specify the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter – since it's so close!).

The optional *exitmsg* argument specifies an exit message printed when exiting. Pass the empty string to suppress the exit message. If *exitmsg* is not given or `None`, a default message is printed.

*Changed in version 3.4:* To suppress printing any banner, pass an empty string.

*Changed in version 3.6:* Print an exit message when exiting.

`InteractiveConsole.push(line)`

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter's `runsource()` method is called with the concatenated contents of the buffer as source. If this indicates that the

command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as `runsource()`).

`InteractiveConsole.resetbuffer()`

Remove any unhandled source text from the input buffer.

`InteractiveConsole.raw_input(prompt="")`

Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence, `EOFError` is raised. The base implementation reads from `sys.stdin`; a subclass may replace this with a different implementation.

# codeop — Compile Python code

**Source code:** [Lib/codeop.py](https://github.com/python/cpython/tree/3.12/Lib/codeop.py) [https://github.com/python/cpython/tree/3.12/Lib/codeop.py]

---

The `codeop` module provides utilities upon which the Python read-eval-print loop can be emulated, as is done in the `code` module. As a result, you probably don't want to use the module directly; if you want to include such a loop in your program you probably want to use the `code` module instead.

There are two parts to this job:

1. Being able to tell if a line of input completes a Python statement: in short, telling whether to print '>>>' or '...' next.
2. Remembering which future statements the user has entered, so subsequent input can be compiled with these in effect.

The `codeop` module provides a way of doing each of these things, and a way of doing them both.

To do just the former:

```
codeop.compile_command(source, filename = '<input>',  
symbol = 'single')
```

Tries to compile *source*, which should be a string of Python code and return a code object if *source* is valid Python code. In that case, the filename attribute of the code object will be *filename*, which defaults to '*<input>*'. Returns `None` if *source* is *not* valid Python code, but is a prefix of valid Python code.

If there is a problem with *source*, an exception will be raised.

**SyntaxError** is raised if there is invalid Python syntax, and **OverflowError** or **ValueError** if there is an invalid literal.

The *symbol* argument determines whether *source* is compiled as a statement ('single', the default), as a sequence of **statement** ('exec') or as an **expression** ('eval'). Any other value will cause **ValueError** to be raised.

### Note

It is possible (but not likely) that the parser stops parsing with a successful outcome before reaching the end of the source; in this case, trailing symbols may be ignored instead of causing an error. For example, a backslash followed by two newlines may be followed by arbitrary garbage. This will be fixed once the API for the parser is better.

### *class* codeop.Compile

Instances of this class have **\_\_call\_\_()** methods identical in signature to the built-in function **compile()**, but with the difference that if the instance compiles program text containing a **\_\_future\_\_** statement, the instance ‘remembers’ and compiles all subsequent program texts with the statement in force.

### *class* codeop.CommandCompiler

Instances of this class have **\_\_call\_\_()** methods identical in signature to **compile\_command()**; the difference is that if the instance compiles program text containing a **\_\_future\_\_** statement, the instance ‘remembers’ and compiles all subsequent program texts with the statement in force.

# Importing Modules

The modules described in this chapter provide new ways to import other Python modules and hooks for customizing the import process.

The full list of modules described in this chapter is:

- **zipimport** — Import modules from Zip archives
  - **zipimporter** Objects
  - Examples
- **pkgutil** — Package extension utility
- **modulefinder** — Find modules used by a script
  - Example usage of **ModuleFinder**
- **runpy** — Locating and executing Python modules
- **importlib** — The implementation of **import**
  - Introduction
  - Functions
  - **importlib.abc** – Abstract base classes related to import
  - **importlib.machinery** – Importers and path hooks
  - **importlib.util** – Utility code for importers
  - Examples
    - Importing programmatically
    - Checking if a module can be imported
    - Importing a source file directly
    - Implementing lazy imports
    - Setting up an importer
    - Approximating `importlib.import_module()`

- **importlib.resources** – Package resource reading, opening and access
  - Deprecated functions
- **importlib.resources.abc** – Abstract base classes for resources
- **importlib.metadata** – Accessing package metadata
  - Overview
  - Functional API
    - Entry points
    - Distribution metadata
    - Distribution versions
    - Distribution files
    - Distribution requirements
    - Mapping import to distribution packages
  - Distributions
  - Distribution Discovery
  - Extending the search algorithm
- The initialization of the **sys.path** module search path
  - Virtual environments
  - `_pth` files
  - Embedded Python

# zipimport — Import modules from Zip archives

**Source code:** [Lib/zipimport.py](https://github.com/python/cpython/tree/3.12/Lib/zipimport.py) [https://github.com/python/cpython/tree/3.12/Lib/zipimport.py]

---

This module adds the ability to import Python modules (`*.py`, `*.pyc`) and packages from ZIP-format archives. It is usually not needed to use the `zipimport` module explicitly; it is automatically used by the built-in `import` mechanism for `sys.path` items that are paths to ZIP archives.

Typically, `sys.path` is a list of directory names as strings. This module also allows an item of `sys.path` to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path `example.zip/lib/` would only import from the `lib/` subdirectory within the archive.

Any files may be present in the ZIP archive, but importers are only invoked for `.py` and `.pyc` files. ZIP import of dynamic modules (`.pyd`, `.so`) is disallowed. Note that if an archive only contains `.py` files, Python will not attempt to modify the archive by adding the corresponding `.pyc` file, meaning that if a ZIP archive doesn't contain `.pyc` files, importing may be rather slow.

*Changed in version 3.8:* Previously, ZIP archives with an archive comment were not supported.

## See also

**PKZIP Application Note** [https://pkware.cachefly.net/webdocs/casestudies/APPNOTE.TXT]

Documentation on the ZIP file format by Phil Katz, the

creator of the format and algorithms used.

### **PEP 273** [<https://peps.python.org/pep-0273/>] - Import Modules from Zip Archives

Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in **PEP 273** [<https://peps.python.org/pep-0273/>], but uses an implementation written by Just van Rossum that uses the import hooks described in **PEP 302** [<https://peps.python.org/pep-0302/>].

### **importlib** - The implementation of the import machinery

Package providing the relevant protocols for all importers to implement.

This module defines an exception:

*exception* `zipimport.ZipImportError`

Exception raised by `zipimporter` objects. It's a subclass of **ImportError**, so it can be caught as **ImportError**, too.

## zipimporter Objects

**zipimporter** is the class for importing ZIP files.

*class* `zipimport.zipimporter(archivepath)`

Create a new `zipimporter` instance. *archivepath* must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an *archivepath* of `foo/bar.zip/lib` will look for modules in the `lib` directory inside the ZIP file `foo/bar.zip` (provided that it exists).

**ZipImportError** is raised if *archivepath* doesn't point to a valid ZIP archive.

*Changed in version 3.12:* Methods `find_loader()` and `find_module()`, deprecated in 3.10 are now removed. Use **`find_spec()`** instead.

`create_module(spec)`

Implementation of

`importlib.abc.Loader.create_module()` that returns `None` to explicitly request the default semantics.

*New in version 3.10.*

`exec_module(module)`

Implementation of

`importlib.abc.Loader.exec_module()`.

*New in version 3.10.*

`find_spec(fullname, target=None)`

An implementation of

`importlib.abc.PathEntryFinder.find_spec()`.

*New in version 3.10.*

`get_code(fullname)`

Return the code object for the specified module. Raise `ZipImportError` if the module couldn't be imported.

`get_data(pathname)`

Return the data associated with *pathname*. Raise `OSError` if the file wasn't found.

*Changed in version 3.3:* `IOError` used to be raised, it is now an alias of `OSError`.

`get_filename(fullname)`

Return the value `__file__` would be set to if the specified module was imported. Raise `ZipImportError` if the module couldn't be imported.

*New in version 3.1.*

`get_source(fullname)`

Return the source code for the specified module. Raise `ZipImportError` if the module couldn't be found, return `None` if the archive does contain the module, but has no source for it.

`is_package(fullname)`

Return `True` if the module specified by *fullname* is a package. Raise `ZipImportError` if the module couldn't be found.

`load_module(fullname)`

Load the module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. Returns the imported module on success, raises `ZipImportError` on failure.

*Deprecated since version 3.10:* Use `exec_module()` instead.

`invalidate_caches()`

Clear out the internal cache of information about files found within the ZIP archive.

*New in version 3.10.*

`archive`

The file name of the importer's associated ZIP file, without a possible subpath.

`prefix`

The subpath within the ZIP file where modules are searched. This is the empty string for `zipimporter` objects which point to the root of the ZIP file.

The `archive` and `prefix` attributes, when combined with a slash, equal the original *archivepath* argument given to the

`zipimporter` constructor.

## Examples

Here is an example that imports a module from a ZIP archive - note that the `zipimport` module is not explicitly used.

```
$ unzip -l example.zip
Archive:  example.zip
  Length      Date    Time    Name
-----
      8467   11-26-02  22:30   jwzthreading.py
-----
      8467                   1 file

$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, 'example.zip')  # Add .zip file to path
>>> import jwzthreading
>>> jwzthreading.__file__
'example.zip/jwzthreading.py'
```

# pkgutil — Package extension utility

**Source code:** [Lib/pkgutil.py](https://github.com/python/cpython/tree/3.12/Lib/pkgutil.py) [https://github.com/python/cpython/tree/3.12/Lib/pkgutil.py]

---

This module provides utilities for the import system, in particular package support.

`class pkgutil.ModuleInfo(module_finder, name, ispkg)`

A namedtuple that holds a brief summary of a module's info.

*New in version 3.6.*

`pkgutil.extend_path(path, name)`

Extend the search path for the modules which comprise a package. Intended use is to place the following code in a package's `__init__.py`:

```
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
```

For each directory on `sys.path` that has a subdirectory that matches the package name, add the subdirectory to the package's `__path__`. This is useful if one wants to distribute different parts of a single logical package as multiple directories.

It also looks for `*.pkg` files beginning where `*` matches the `name` argument. This feature is similar to `*.pth` files (see the `site` module for more information), except that it doesn't special-case lines starting with `import`. A `*.pkg` file is trusted at face value: apart from checking for duplicates, all entries found in a `*.pkg` file are added to the path,

regardless of whether they exist on the filesystem. (This is a feature.)

If the input path is not a list (as is the case for frozen packages) it is returned unchanged. The input path is not modified; an extended copy is returned. Items are only appended to the copy at the end.

It is assumed that `sys.path` is a sequence. Items of `sys.path` that are not strings referring to existing directories are ignored. Unicode items on `sys.path` that cause errors when used as filenames may cause this function to raise an exception (in line with `os.path.isdir()` behavior).

`pkgutil.find_loader(fullname)`

Retrieve a module `loader` for the given `fullname`.

This is a backwards compatibility wrapper around `importlib.util.find_spec()` that converts most failures to `ImportError` and only returns the loader rather than the full `importlib.machinery.ModuleSpec`.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/] import emulation.

*Changed in version 3.4:* Updated to be based on [PEP 451](https://peps.python.org/pep-0451/) [https://peps.python.org/pep-0451/]

*Deprecated since version 3.12, will be removed in version 3.14:* Use `importlib.util.find_spec()` instead.

`pkgutil.get_importer(path_item)`

Retrieve a `finder` for the given `path_item`.

The returned finder is cached in `sys.path_importer_cache` if it was newly created by a path hook.

The cache (or part of it) can be cleared manually if a rescan

of `sys.path_hooks` is necessary.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/] import emulation.

`pkgutil.get_loader(module_or_name)`

Get a `loader` object for `module_or_name`.

If the module or package is accessible via the normal import mechanism, a wrapper around the relevant part of that machinery is returned. Returns `None` if the module cannot be found or imported. If the named module is not already imported, its containing package (if any) is imported, in order to establish the package `__path__`.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/] import emulation.

*Changed in version 3.4:* Updated to be based on [PEP 451](https://peps.python.org/pep-0451/) [https://peps.python.org/pep-0451/]

*Deprecated since version 3.12, will be removed in version 3.14:*  
Use `importlib.util.find_spec()` instead.

`pkgutil.iter_importers(fullname="")`

Yield `finder` objects for the given module name.

If `fullname` contains a `'.'`, the finders will be for the package containing `fullname`, otherwise they will be all registered top level finders (i.e. those on both `sys.meta_path` and `sys.path_hooks`).

If the named module is in a package, that package is imported as a side effect of invoking this function.

If no module name is specified, all top level finders are produced.

*Changed in version 3.3:* Updated to be based directly on

`importlib` rather than relying on the package internal [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/] import emulation.

`pkgutil.iter_modules(path=None, prefix="")`

Yields `ModuleInfo` for all submodules on *path*, or, if *path* is `None`, all top-level modules on `sys.path`.

*path* should be either `None` or a list of paths to look for modules in.

*prefix* is a string to output on the front of every module name on output.

### Note

Only works for a `finder` which defines an `iter_modules()` method. This interface is non-standard, so the module also provides implementations for `importlib.machinery.FileFinder` and `zipimport.zipimporter`.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/] import emulation.

`pkgutil.walk_packages(path=None, prefix="", onerror=None)`

Yields `ModuleInfo` for all modules recursively on *path*, or, if *path* is `None`, all accessible modules.

*path* should be either `None` or a list of paths to look for modules in.

*prefix* is a string to output on the front of every module name on output.

Note that this function must import all *packages* (not all modules!) on the given *path*, in order to access the `__path__` attribute to find submodules.

*onerror* is a function which gets called with one argument (the

name of the package which was being imported) if any exception occurs while trying to import a package. If no *onerror* function is supplied, `ImportErrors` are caught and ignored, while all other exceptions are propagated, terminating the search.

Examples:

```
# list all modules python can access
walk_packages()
```

```
# list all submodules of ctypes
walk_packages(ctypes.__path__, ctypes.__name__ + '.')
```

### Note

Only works for a `finder` which defines an `iter_modules()` method. This interface is non-standard, so the module also provides implementations for `importlib.machinery.FileFinder` and `zipimport.zipimporter`.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/] import emulation.

`pkgutil.get_data(package, resource)`

Get a resource from a package.

This is a wrapper for the `loader.get_data` API. The *package* argument should be the name of a package, in standard module format (`foo.bar`). The *resource* argument should be in the form of a relative filename, using `/` as the path separator. The parent directory name `..` is not allowed, and nor is a rooted name (starting with a `/`).

The function returns a binary string that is the contents of the specified resource.

For packages located in the filesystem, which have already

been imported, this is the rough equivalent of:

```
d = os.path.dirname(sys.modules[package].__file__)
data = open(os.path.join(d, resource), 'rb').read()
```

If the package cannot be located or loaded, or it uses a [loader](#) which does not support [get\\_data](#), then `None` is returned. In particular, the [loader](#) for [namespace packages](#) does not support [get\\_data](#).

`pkgutil.resolve_name(name)`

Resolve a name to an object.

This functionality is used in numerous places in the standard library (see [bpo-12915](#) [<https://bugs.python.org/issue?@action=redirect&bpo=12915>]) - and equivalent functionality is also in widely used third-party packages such as `setuptools`, `Django` and `Pyramid`.

It is expected that *name* will be a string in one of the following formats, where *W* is shorthand for a valid Python identifier and *dot* stands for a literal period in these pseudo-regexes:

- `W (.W) *`
- `W (.W) *: (W (.W) *) ?`

The first form is intended for backward compatibility only. It assumes that some part of the dotted name is a package, and the rest is an object somewhere within that package, possibly nested inside other objects. Because the place where the package stops and the object hierarchy starts can't be inferred by inspection, repeated attempts to import must be done with this form.

In the second form, the caller makes the division point clear through the provision of a single colon: the dotted name to the left of the colon is a package to be imported, and the dotted name to the right is the object hierarchy within that package. Only one import is needed in this form. If it ends with the colon, then a module object is returned.

The function will return an object (which might be a module), or raise one of the following exceptions:

**ValueError** – if *name* isn't in a recognised format.

**ImportError** – if an import failed when it shouldn't have.

**AttributeError** – If a failure occurred when traversing the object hierarchy within the imported package to get to the desired object.

*New in version 3.9.*

# modulefinder — Find modules used by a script

**Source code:** [Lib/modulefinder.py](https://github.com/python/cpython/tree/3.12/Lib/modulefinder.py) [https://github.com/python/cpython/tree/3.12/Lib/modulefinder.py]

---

This module provides a `ModuleFinder` class that can be used to determine the set of modules imported by a script. `modulefinder.py` can also be run as a script, giving the filename of a Python script as its argument, after which a report of the imported modules will be printed.

`modulefinder.AddPackagePath(pkg_name, path)`

Record that the package named *pkg\_name* can be found in the specified *path*.

`modulefinder.ReplacePackage(oldname, newname)`

Allows specifying that the module named *oldname* is in fact the package named *newname*.

`class modulefinder.ModuleFinder(path=None, debug=0, excludes=[], replace_paths=[])`

This class provides `run_script()` and `report()` methods to determine the set of modules imported by a script. *path* can be a list of directories to search for modules; if not specified, `sys.path` is used. *debug* sets the debugging level; higher values make the class print debugging messages about what it's doing. *excludes* is a list of module names to exclude from the analysis. *replace\_paths* is a list of (*oldpath*, *newpath*) tuples that will be replaced in module paths.

`report()`

Print a report to standard output that lists the modules imported by the script and their paths, as well as modules that are missing or seem to be missing.

`run_script(pathname)`

Analyze the contents of the *pathname* file, which must contain Python code.

`modules`

A dictionary mapping module names to modules. See [Example usage of ModuleFinder](#).

## Example usage of **ModuleFinder**

The script that is going to get analyzed later on (bacon.py):

```
import re, itertools

try:
    import baconhameggs
except ImportError:
    pass

try:
    import guido.python.ham
except ImportError:
    pass
```

The script that will output the report of bacon.py:

```
from modulefinder import ModuleFinder

finder = ModuleFinder()
finder.run_script('bacon.py')

print('Loaded modules:')
for name, mod in finder.modules.items():
    print('%s: ' % name, end='')
```

```
print(','.join(list(mod.globalnames.keys())[0:3]))

print('-'*50)
print('Modules not imported:')
print('\n'.join(finder.badmodules.keys()))
```

**Sample output (may vary depending on the architecture):**

```
Loaded modules:
_types:
copyreg:  _inverted_registry, _slotnames, __all__
re._compiler:  isstring, _sre, _optimize_unicode
_sre:
re._constants:  REPEAT_ONE, makedict, AT_END_LINE
sys:
re:  __module__, finditer, _expand
itertools:
__main__:  re, itertools, baconhameggs
re._parser:  _PATTERNENDERS, SRE_FLAG_UNICODE
array:
types:  __module__, IntType, TypeType
-----
```

```
Modules not imported:
guido.python.ham
baconhameggs
```

# runpy — Locating and executing Python modules

Source code: [Lib/runpy.py](https://github.com/python/cpython/tree/3.12/Lib/runpy.py) [https://github.com/python/cpython/tree/3.12/Lib/runpy.py]

---

The **runpy** module is used to locate and run Python modules without importing them first. Its main use is to implement the **-m** command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

Note that this is *not* a sandbox module - all code is executed in the current process, and any side effects (such as cached imports of other modules) will remain in place after the functions have returned.

Furthermore, any functions and classes defined by the executed code are not guaranteed to work correctly after a **runpy** function has returned. If that limitation is not acceptable for a given use case, **importlib** is likely to be a more suitable choice than this module.

The **runpy** module provides two functions:

`runpy.run_module(mod_name, init_globals=None, run_name=None, alter_sys=False)`

Execute the code of the specified module and return the resulting module globals dictionary. The module's code is first located using the standard import mechanism (refer to [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/] for details) and then executed in a fresh module namespace.

The *mod\_name* argument should be an absolute module name. If the module name refers to a package rather than a normal

module, then that package is imported and the `__main__` submodule within that package is then executed and the resulting module globals dictionary returned.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by `run_module()`.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

`__name__` is set to `run_name` if this optional argument is not `None`, to `mod_name + '.__main__'` if the named module is a package and to the `mod_name` argument otherwise.

`__spec__` will be set appropriately for the *actually* imported module (that is, `__spec__.name` will always be `mod_name` or `mod_name + '.__main__'`, never `run_name`).

`__file__`, `__cached__`, `__loader__` and `__package__` are **set as normal** based on the module spec.

If the argument `alter_sys` is supplied and evaluates to `True`, then `sys.argv[0]` is updated with the value of `__file__` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. Both `sys.argv[0]` and `sys.modules[__name__]` are restored to their original values before the function returns.

Note that this manipulation of `sys` is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the `sys` module be left alone when invoking this function from threaded code.

## See also

The `-m` option offering equivalent functionality from the command line.

*Changed in version 3.1:* Added ability to execute packages by looking for a `__main__` submodule.

*Changed in version 3.2:* Added `__cached__` global variable (see [PEP 3147](https://peps.python.org/pep-3147/) [https://peps.python.org/pep-3147/]).

*Changed in version 3.4:* Updated to take advantage of the module spec feature added by [PEP 451](https://peps.python.org/pep-0451/) [https://peps.python.org/pep-0451/]. This allows `__cached__` to be set correctly for modules run this way, as well as ensuring the real module name is always accessible as `__spec__.name`.

*Changed in version 3.12:* The setting of `__cached__`, `__loader__`, and `__package__` are deprecated. See [ModuleSpec](#) for alternatives.

`runpy.run_path(path_name, init_globals=None, run_name=None)`

Execute the code at the named filesystem location and return the resulting module globals dictionary. As with a script name supplied to the CPython command line, the supplied path may refer to a Python source file, a compiled bytecode file or a valid [sys.path](#) entry containing a `__main__` module (e.g. a zipfile containing a top-level `__main__.py` file).

For a simple script, the specified code is simply executed in a fresh module namespace. For a valid [sys.path](#) entry (typically a zipfile or directory), the entry is first added to the beginning of `sys.path`. The function then looks for and executes a `__main__` module using the updated path. Note that there is no special protection against invoking an existing `__main__` entry located elsewhere on `sys.path` if there is no such module at the specified location.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code

is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by `run_path()`.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

`__name__` is set to `run_name` if this optional argument is not `None` and to `'<run_path>'` otherwise.

If the supplied path directly references a script file (whether as source or as precompiled byte code), then `__file__` will be set to the supplied path, and `__spec__`, `__cached__`, `__loader__` and `__package__` will all be set to `None`.

If the supplied path is a reference to a valid `sys.path` entry, then `__spec__` will be set appropriately for the imported `__main__` module (that is, `__spec__.name` will always be `__main__`). `__file__`, `__cached__`, `__loader__` and `__package__` will be `set as normal` based on the module spec.

A number of alterations are also made to the `sys` module. Firstly, `sys.path` may be altered as described above. `sys.argv[0]` is updated with the value of `path_name` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. All modifications to items in `sys` are reverted before the function returns.

Note that, unlike `run_module()`, the alterations made to `sys` are not optional in this function as these adjustments are essential to allowing the execution of `sys.path` entries. As the thread-safety limitations still apply, use of this function in threaded code should be either serialised with the import lock or delegated to a separate process.

## See also

[Interface options](#) for equivalent functionality on the command line (`python path/to/script`).

*New in version 3.2.*

*Changed in version 3.4:* Updated to take advantage of the module spec feature added by [PEP 451](#) [<https://peps.python.org/pep-0451/>]. This allows `__cached__` to be set correctly in the case where `__main__` is imported from a valid `sys.path` entry rather than being executed directly.

*Changed in version 3.12:* The setting of `__cached__`, `__loader__`, and `__package__` are deprecated.

# importlib — The implementation of `import`

*New in version 3.1.*

**Source code:** [Lib/importlib/\\_init\\_.py](https://github.com/python/cpython/tree/3.12/Lib/importlib/_init_.py) [https://github.com/python/cpython/tree/3.12/Lib/importlib/\_init\_.py]

---

## Introduction

The purpose of the `importlib` package is three-fold.

One is to provide the implementation of the `import` statement (and thus, by extension, the `__import__()` function) in Python source code. This provides an implementation of `import` which is portable to any Python interpreter. This also provides an implementation which is easier to comprehend than one implemented in a programming language other than Python.

Two, the components to implement `import` are exposed in this package, making it easier for users to create their own custom objects (known generically as an `importer`) to participate in the import process.

Three, the package contains modules exposing additional functionality for managing aspects of Python packages:

- `importlib.metadata` presents access to metadata from third-party distributions.
- `importlib.resources` provides routines for accessing non-code “resources” from Python packages.

## Functions

`importlib._import_(name, globals=None, locals=None, fromlist=(), level=0)`

An implementation of the built-in `__import__()` function.

### Note

Programmatic importing of modules should use `import_module()` instead of this function.

`importlib.import_module(name, package=None)`

Import a module. The *name* argument specifies what module to import in absolute or relative terms (e.g. either `pkg.mod` or `..mod`). If the name is specified in relative terms, then the *package* argument must be set to the name of the package which is to act as the anchor for resolving the package name (e.g. `import_module('..mod', 'pkg.subpkg')` will import `pkg.mod`).

The `import_module()` function acts as a simplifying wrapper around `importlib._import__()`. This means all semantics of the function are derived from `importlib._import__()`. The most important difference between these two functions is that `import_module()` returns the specified package or module (e.g. `pkg.mod`), while `__import__()` returns the top-level package or module (e.g. `pkg`).

If you are dynamically importing a module that was created since the interpreter began execution (e.g., created a Python source file), you may need to call `invalidate_caches()` in order for the new module to be noticed by the import system.

*Changed in version 3.3:* Parent packages are automatically imported.

`importlib.invalidate_caches()`

Invalidate the internal caches of finders stored at `sys.meta_path`. If a finder implements `invalidate_caches()` then it will be called to perform the invalidation. This function should be called if any modules are created/installed while your program is running to guarantee all finders will notice the new module's existence.

*New in version 3.3.*

*Changed in version 3.10:* Namespace packages created/installed in a different `sys.path` location after the same namespace was already imported are noticed.

`importlib.reload(module)`

Reload a previously imported *module*. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (which can be different if re-importing causes a different object to be placed in `sys.modules`).

When `reload()` is executed:

- Python module's code is recompiled and the module-level code re-executed, defining a new set of objects which are bound to names in the module's dictionary by reusing the `loader` which originally loaded the module. The `init` function of extension modules is

not called a second time.

- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module's advantage if it maintains a global table or cache of objects — with a **try** statement it can test for the table's presence and skip its initialization if desired:

```
try:
    cache
except NameError:
    cache = {}
```

It is generally not very useful to reload built-in or dynamically loaded modules. Reloading **sys**, **\_\_main\_\_**, **builtins** and other key modules is not recommended. In many cases extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using **from ... import ...**, calling **reload()** for the other module does not redefine the objects imported from it — one way around this is to re-execute the **from** statement, another is to use **import** and qualified names (*module.name*) instead.

If a module instantiates instances of a class, reloading the

module that defines the class does not affect the method definitions of the instances — they continue to use the old class definition. The same is true for derived classes.

*New in version 3.4.*

*Changed in version 3.7:* `ModuleNotFoundError` is raised when the module being reloaded lacks a `ModuleSpec`.

## `importlib.abc` – Abstract base classes related to import

**Source code:** [Lib/importlib/abc.py](https://github.com/python/cpython/tree/3.12/Lib/importlib/abc.py) [https://github.com/python/cpython/tree/3.12/Lib/importlib/abc.py]

---

The `importlib.abc` module contains all of the core abstract base classes used by `import`. Some subclasses of the core abstract base classes are also provided to help in implementing the core ABCs.

ABC hierarchy:

```
object
+-- MetaPathFinder
+-- PathEntryFinder
+-- Loader
    +-- ResourceLoader -----+
    +-- InspectLoader          |
        +-- ExecutionLoader --+
                                   +-- FileLoader
                                   +-- SourceLoader
```

`class importlib.abc.MetaPathFinder`

An abstract base class representing a [meta path finder](#).

*New in version 3.3.*

*Changed in version 3.10:* No longer a subclass of `Finder`.

`find_spec(fullname, path, target=None)`

An abstract method for finding a [spec](#) for the specified module. If this is a top-level import, *path* will be `None`. Otherwise, this is a search for a subpackage or module and *path* will be the value of [\\_\\_path\\_\\_](#) from the parent package. If a spec cannot be found, `None` is returned. When passed in, *target* is a module object that the finder may use to make a more educated guess about what spec to return.

[importlib.util.spec\\_from\\_loader\(\)](#) may be useful for implementing concrete `MetaPathFinders`.

*New in version 3.4.*

`invalidate_caches()`

An optional method which, when called, should invalidate any internal cache used by the finder. Used by [importlib.invalidate\\_caches\(\)](#) when invalidating the caches of all finders on [sys.meta\\_path](#).

*Changed in version 3.4:* Returns `None` when called instead of `NotImplemented`.

`class importlib.abc.PathEntryFinder`

An abstract base class representing a [path entry finder](#). Though it bears some similarities to [MetaPathFinder](#), `PathEntryFinder` is meant for use only within the path-based import subsystem provided by [importlib.machinery.PathFinder](#).

*New in version 3.3.*

*Changed in version 3.10:* No longer a subclass of `Finder`.

`find_spec(fullname, target=None)`

An abstract method for finding a [spec](#) for the specified module. The finder will search for the module only within the [path entry](#) to which it is assigned. If a spec cannot be found, `None` is returned. When passed in,

target is a module object that the finder may use to make a more educated guess about what spec to return. `importlib.util.spec_from_loader()` may be useful for implementing concrete `PathEntryFinders`.

*New in version 3.4.*

`invalidate_caches()`

An optional method which, when called, should invalidate any internal cache used by the finder. Used by

`importlib.machinery.PathFinder.invalidate_caches()` when invalidating the caches of all cached finders.

*class* `importlib.abc.Loader`

An abstract base class for a [loader](#). See [PEP 302](#) [<https://peps.python.org/pep-0302/>] for the exact definition for a loader.

Loaders that wish to support resource reading should implement a `get_resource_reader()` method as specified by

`importlib.resources.abc.ResourceReader`.

*Changed in version 3.7:* Introduced the optional `get_resource_reader()` method.

`create_module(spec)`

A method that returns the module object to use when importing a module. This method may return `None`, indicating that default module creation semantics should take place.

*New in version 3.4.*

*Changed in version 3.6:* This method is no longer optional when `exec_module()` is defined.

`exec_module(module)`

An abstract method that executes the module in its own namespace when a module is imported or reloaded. The module should already be initialized when `exec_module()` is called. When this method exists, `create_module()` must be defined.

*New in version 3.4.*

*Changed in version 3.6:* `create_module()` must also be defined.

### `load_module(fullname)`

A legacy method for loading a module. If the module cannot be loaded, `ImportError` is raised, otherwise the loaded module is returned.

If the requested module already exists in `sys.modules`, that module should be used and reloaded. Otherwise the loader should create a new module and insert it into `sys.modules` before any loading begins, to prevent recursion from the import. If the loader inserted a module and the load fails, it must be removed by the loader from `sys.modules`; modules already in `sys.modules` before the loader began execution should be left alone.

The loader should set several attributes on the module (note that some of these attributes can change when a module is reloaded):

- `__name__`  
The module's fully qualified name. It is `'__main__'` for an executed module.
- `__file__`  
The location the loader used to load the module. For example, for modules loaded from a .py file this is the filename. It is not set on all modules (e.g. built-in modules).

- `__cached__`  
The filename of a compiled version of the module's code. It is not set on all modules (e.g. built-in modules).
- `__path__`  
The list of locations where the package's submodules will be found. Most of the time this is a single directory. The import system passes this attribute to `__import__()` and to finders in the same way as `sys.path` but just for the package. It is not set on non-package modules so it can be used as an indicator that the module is a package.
- `__package__`  
The fully qualified name of the package the module is in (or the empty string for a top-level module). If the module is a package then this is the same as `__name__`.
- `__loader__`  
The `loader` used to load the module.

When `exec_module()` is available then backwards-compatible functionality is provided.

*Changed in version 3.4:* Raise `ImportError` when called instead of `NotImplementedError`.  
Functionality provided when `exec_module()` is available.

*Deprecated since version 3.4:* The recommended API for loading a module is `exec_module()` (and `create_module()`). Loaders should implement it instead of `load_module()`. The import machinery takes care of all the other responsibilities of `load_module()` when `exec_module()` is implemented.

`class importlib.abc.ResourceLoader`

An abstract base class for a [loader](#) which implements the optional [PEP 302](#) [<https://peps.python.org/pep-0302/>] protocol for loading arbitrary resources from the storage back-end.

*Deprecated since version 3.7:* This ABC is deprecated in favour of supporting resource loading through

[importlib.resources.abc.ResourceReader](#).

*abstractmethod* `get_data(path)`

An abstract method to return the bytes for the data located at *path*. Loaders that have a file-like storage back-end that allows storing arbitrary data can implement this abstract method to give direct access to the data stored. [OSError](#) is to be raised if the *path* cannot be found. The *path* is expected to be constructed using a module's `__file__` attribute or an item from a package's `__path__`.

*Changed in version 3.4:* Raises [OSError](#) instead of [NotImplementedError](#).

`class importlib.abc.InspectLoader`

An abstract base class for a [loader](#) which implements the optional [PEP 302](#) [<https://peps.python.org/pep-0302/>] protocol for loaders that inspect modules.

`get_code(fullname)`

Return the code object for a module, or `None` if the module does not have a code object (as would be the case, for example, for a built-in module). Raise an [ImportError](#) if loader cannot find the requested module.

### Note

While the method has a default implementation, it is suggested that it be overridden if possible for performance.

*Changed in version 3.4:* No longer abstract and a concrete implementation is provided.

*abstractmethod* `get_source(fullname)`

An abstract method to return the source of a module. It is returned as a text string using `universal newlines`, translating all recognized line separators into `'\n'` characters. Returns `None` if no source is available (e.g. a built-in module). Raises `ImportError` if the loader cannot find the module specified.

*Changed in version 3.4:* Raises `ImportError` instead of `NotImplementedError`.

*is\_package*(`fullname`)

An optional method to return a true value if the module is a package, a false value otherwise. `ImportError` is raised if the `loader` cannot find the module.

*Changed in version 3.4:* Raises `ImportError` instead of `NotImplementedError`.

*static* `source_to_code(data, path='<string>')`

Create a code object from Python source.

The *data* argument can be whatever the `compile()` function supports (i.e. string or bytes). The *path* argument should be the “path” to where the source code originated from, which can be an abstract concept (e.g. location in a zip file).

With the subsequent code object one can execute it in a module by running `exec(code, module.__dict__)`.

*New in version 3.4.*

*Changed in version 3.5:* Made the method static.

`exec_module(module)`

Implementation of `Loader.exec_module()`.

*New in version 3.4.*

`load_module(fullname)`

Implementation of `Loader.load_module()`.

*Deprecated since version 3.4:* use `exec_module()` instead.

`class importlib.abc.ExecutionLoader`

An abstract base class which inherits from `InspectLoader` that, when implemented, helps a module to be executed as a script. The ABC represents an optional [PEP 302](https://peps.python.org/pep-0302/) protocol.

*abstractmethod* `get_filename(fullname)`

An abstract method that is to return the value of `__file__` for the specified module. If no path is available, `ImportError` is raised.

If source code is available, then the method should return the path to the source file, regardless of whether a bytecode was used to load the module.

*Changed in version 3.4:* Raises `ImportError` instead of `NotImplementedError`.

`class importlib.abc.FileLoader(fullname, path)`

An abstract base class which inherits from `ResourceLoader` and `ExecutionLoader`, providing concrete implementations of `ResourceLoader.get_data()` and `ExecutionLoader.get_filename()`.

The *fullname* argument is a fully resolved name of the module the loader is to handle. The *path* argument is the path to the file for the module.

*New in version 3.3.*

**name**

The name of the module the loader can handle.

**path**

Path to the file of the module.

**load\_module(fullname)**

Calls super's `load_module()`.

*Deprecated since version 3.4:* Use `Loader.exec_module()` instead.

*abstractmethod* **get\_filename(fullname)**

Returns **path**.

*abstractmethod* **get\_data(path)**

Reads *path* as a binary file and returns the bytes from it.

*class* `importlib.abc.SourceLoader`

An abstract base class for implementing source (and optionally bytecode) file loading. The class inherits from both `ResourceLoader` and `ExecutionLoader`, requiring the implementation of:

- `ResourceLoader.get_data()`
- `ExecutionLoader.get_filename()`  
Should only return the path to the source file; sourceless loading is not supported.

The abstract methods defined by this class are to add optional bytecode file support. Not implementing these optional methods (or causing them to raise `NotImplementedError`) causes the loader to only work with source code. Implementing the methods allows the loader to work with source *and* bytecode files; it does not allow for *sourceless*

loading where only bytecode is provided. Bytecode files are an optimization to speed up loading by removing the parsing step of Python's compiler, and so no bytecode-specific API is exposed.

### `path_stats(path)`

Optional abstract method which returns a **dict** containing metadata about the specified path. Supported dictionary keys are:

- `'mtime'` (mandatory): an integer or floating-point number representing the modification time of the source code;
- `'size'` (optional): the size in bytes of the source code.

Any other keys in the dictionary are ignored, to allow for future extensions. If the path cannot be handled, **OSError** is raised.

*New in version 3.3.*

*Changed in version 3.4:* Raise **OSError** instead of **NotImplementedError**.

### `path_mtime(path)`

Optional abstract method which returns the modification time for the specified path.

*Deprecated since version 3.3:* This method is deprecated in favour of **path\_stats()**. You don't have to implement it, but it is still available for compatibility purposes. Raise **OSError** if the path cannot be handled.

*Changed in version 3.4:* Raise **OSError** instead of **NotImplementedError**.

### `set_data(path, data)`

Optional abstract method which writes the specified

bytes to a file path. Any intermediate directories which do not exist are to be created automatically.

When writing to the path fails because the path is read-only (`errno.EACCES/PermissionError`), do not propagate the exception.

*Changed in version 3.4:* No longer raises `NotImplementedError` when called.

`get_code(fullname)`

Concrete implementation of  
`InspectLoader.get_code()`.

`exec_module(module)`

Concrete implementation of  
`Loader.exec_module()`.

*New in version 3.4.*

`load_module(fullname)`

Concrete implementation of  
`Loader.load_module()`.

*Deprecated since version 3.4:* Use `exec_module()` instead.

`get_source(fullname)`

Concrete implementation of  
`InspectLoader.get_source()`.

`is_package(fullname)`

Concrete implementation of  
`InspectLoader.is_package()`. A module is determined to be a package if its file path (as provided by `ExecutionLoader.get_filename()`) is a file named `__init__` when the file extension is removed **and** the module name itself does not end in

`__init__`.

`class importlib.abc.ResourceReader`

*Superseded by `TraversableResources`*

An [abstract base class](#) to provide the ability to read *resources*.

From the perspective of this ABC, a *resource* is a binary artifact that is shipped within a package. Typically this is something like a data file that lives next to the `__init__.py` file of the package. The purpose of this class is to help abstract out the accessing of such data files so that it does not matter if the package and its data file(s) are stored in a e.g. zip file versus on the file system.

For any of methods of this class, a *resource* argument is expected to be a [path-like object](#) which represents conceptually just a file name. This means that no subdirectory paths should be included in the *resource* argument. This is because the location of the package the reader is for, acts as the “directory”. Hence the metaphor for directories and file names is packages and resources, respectively. This is also why instances of this class are expected to directly correlate to a specific package (instead of potentially representing multiple packages or a module).

Loaders that wish to support resource reading are expected to provide a method called

`get_resource_reader(fullname)` which returns an object implementing this ABC’s interface. If the module specified by `fullname` is not a package, this method should return **None**. An object compatible with this ABC should only be returned when the specified module is a package.

*New in version 3.7.*

*Deprecated since version 3.12, will be removed in version 3.14:*

Use

[importlib.resources.abc.TraversableResources](#) instead.

*abstractmethod* open\_resource(resource)

Returns an opened, [file-like object](#) for binary reading of the *resource*.

If the resource cannot be found, [FileNotFoundError](#) is raised.

*abstractmethod* resource\_path(resource)

Returns the file system path to the *resource*.

If the resource does not concretely exist on the file system, raise [FileNotFoundError](#).

*abstractmethod* is\_resource(name)

Returns `True` if the named *name* is considered a resource. [FileNotFoundError](#) is raised if *name* does not exist.

*abstractmethod* contents()

Returns an [iterable](#) of strings over the contents of the package. Do note that it is not required that all names returned by the iterator be actual resources, e.g. it is acceptable to return names for which [is\\_resource\(\)](#) would be false.

Allowing non-resource names to be returned is to allow for situations where how a package and its resources are stored are known a priori and the non-resource names would be useful. For instance, returning subdirectory names is allowed so that when it is known that the package and resources are stored on the file system then those subdirectory names can be used directly.

The abstract method returns an iterable of no items.

*class* importlib.abc.Traversable

An object with a subset of [pathlib.Path](#) methods suitable

for traversing directories and opening files.

For a representation of the object on the file-system, use `importlib.resources.as_file()`.

*New in version 3.9.*

*Deprecated since version 3.12, will be removed in version 3.14:*

Use `importlib.resources.abc.Traversable` instead.

name

Abstract. The base name of this object without any parent references.

*abstractmethod* `iterdir()`

Yield `Traversable` objects in `self`.

*abstractmethod* `is_dir()`

Return `True` if `self` is a directory.

*abstractmethod* `is_file()`

Return `True` if `self` is a file.

*abstractmethod* `joinpath(child)`

Return `Traversable` child in `self`.

*abstractmethod* `_truediv_(child)`

Return `Traversable` child in `self`.

*abstractmethod* `open(mode='r', *args, **kwargs)`

`mode` may be 'r' or 'rb' to open as text or binary. Return a handle suitable for reading (same as `pathlib.Path.open`).

When opening as text, accepts encoding parameters such as those accepted by `io.TextIOWrapper`.

`read_bytes()`

Read contents of `self` as bytes.

`read_text(encoding=None)`

Read contents of `self` as text.

`class importlib.abc.TraversableResources`

An abstract base class for resource readers capable of serving the `importlib.resources.files()` interface. Subclasses `importlib.resources.abc.ResourceReader` and provides concrete implementations of the `importlib.resources.abc.ResourceReader`'s abstract methods. Therefore, any loader supplying `importlib.abc.TraversableResources` also supplies `ResourceReader`.

Loaders that wish to support resource reading are expected to implement this interface.

*New in version 3.9.*

*Deprecated since version 3.12, will be removed in version 3.14:*

Use

`importlib.resources.abc.TraversableResources` instead.

*abstractmethod* `files()`

Returns a

`importlib.resources.abc.Traversable` object for the loaded package.

## `importlib.machinery` – Importers and path hooks

**Source code:** [Lib/importlib/machinery.py](https://github.com/python/cpython/tree/3.12/Lib/importlib/machinery.py) [https://github.com/python/cpython/tree/3.12/Lib/importlib/machinery.py]

---

This module contains the various objects that help `import` find and load modules.

`importlib.machinery.SOURCE_SUFFIXES`

A list of strings representing the recognized file suffixes for source modules.

*New in version 3.3.*

`importlib.machinery.DEBUG_BYTECODE_SUFFIXES`

A list of strings representing the file suffixes for non-optimized bytecode modules.

*New in version 3.3.*

*Deprecated since version 3.5:* Use `BYTECODE_SUFFIXES` instead.

`importlib.machinery.OPTIMIZED_BYTECODE_SUFFIXES`

A list of strings representing the file suffixes for optimized bytecode modules.

*New in version 3.3.*

*Deprecated since version 3.5:* Use `BYTECODE_SUFFIXES` instead.

`importlib.machinery.BYTECODE_SUFFIXES`

A list of strings representing the recognized file suffixes for bytecode modules (including the leading dot).

*New in version 3.3.*

*Changed in version 3.5:* The value is no longer dependent on `__debug__`.

`importlib.machinery.EXTENSION_SUFFIXES`

A list of strings representing the recognized file suffixes for extension modules.

*New in version 3.3.*

`importlib.machinery.all_suffixes()`

Returns a combined list of strings representing all file suffixes for modules recognized by the standard import machinery. This is a helper for code which simply needs to know if a filesystem path potentially refers to a module without needing any details on the kind of module (for example, `inspect.getmodule()`).

*New in version 3.3.*

`class importlib.machinery.BuiltinImporter`

An `importer` for built-in modules. All known built-in modules are listed in `sys.builtin_module_names`. This class implements the `importlib.abc.MetaPathFinder` and `importlib.abc.InspectLoader` ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

*Changed in version 3.5:* As part of [PEP 489](https://peps.python.org/pep-0489/) [https://peps.python.org/pep-0489/], the builtin importer now implements `Loader.create_module()` and `Loader.exec_module()`

`class importlib.machinery.FrozenImporter`

An `importer` for frozen modules. This class implements the `importlib.abc.MetaPathFinder` and `importlib.abc.InspectLoader` ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

*Changed in version 3.4:* Gained `create_module()` and `exec_module()` methods.

`class importlib.machinery.WindowsRegistryFinder`

`Finder` for modules declared in the Windows registry. This

class implements the `importlib.abc.MetaPathFinder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

*New in version 3.3.*

*Deprecated since version 3.6:* Use `site` configuration instead. Future versions of Python may not enable this finder by default.

*class* `importlib.machinery.PathFinder`

A `Finder` for `sys.path` and package `__path__` attributes. This class implements the `importlib.abc.MetaPathFinder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

*classmethod* `find_spec(fullname, path=None, target=None)`

Class method that attempts to find a `spec` for the module specified by `fullname` on `sys.path` or, if defined, on `path`. For each path entry that is searched, `sys.path_importer_cache` is checked. If a non-`false` object is found then it is used as the `path entry finder` to look for the module being searched for. If no entry is found in `sys.path_importer_cache`, then `sys.path_hooks` is searched for a finder for the path entry and, if found, is stored in `sys.path_importer_cache` along with being queried about the module. If no finder is ever found then `None` is both stored in the cache and returned.

*New in version 3.4.*

*Changed in version 3.5:* If the current working directory – represented by an empty string – is no longer valid then `None` is returned but no value is cached in `sys.path_importer_cache`.

*classmethod* invalidate\_caches()

Calls

`importlib.abc.PathEntryFinder.invalidate_caches` on all finders stored in `sys.path_importer_cache` that define the method. Otherwise entries in `sys.path_importer_cache` set to `None` are deleted.

*Changed in version 3.7:* Entries of `None` in `sys.path_importer_cache` are deleted.

*Changed in version 3.4:* Calls objects in `sys.path_hooks` with the current working directory for `''` (i.e. the empty string).

*class* importlib.machinery.FileFinder(*path*, \**loader\_details*)

A concrete implementation of

`importlib.abc.PathEntryFinder` which caches results from the file system.

The *path* argument is the directory for which the finder is in charge of searching.

The *loader\_details* argument is a variable number of 2-item tuples each containing a loader and a sequence of file suffixes the loader recognizes. The loaders are expected to be callables which accept two arguments of the module's name and the path to the file found.

The finder will cache the directory contents as necessary, making stat calls for each module search to verify the cache is not outdated. Because cache staleness relies upon the granularity of the operating system's state information of the file system, there is a potential race condition of searching for a module, creating a new file, and then searching for the module the new file represents. If the operations happen fast enough to fit within the granularity of stat calls, then the module search will fail. To prevent this from happening, when you create a module dynamically, make sure to call

`importlib.invalidate_caches()`.

*New in version 3.3.*

`path`

The path the finder will search in.

`find_spec(fullname, target=None)`

Attempt to find the spec to handle *fullname* within `path`.

*New in version 3.4.*

`invalidate_caches()`

Clear out the internal cache.

*classmethod* `path_hook(*loader_details)`

A class method which returns a closure for use on `sys.path_hooks`. An instance of `FileFinder` is returned by the closure using the path argument given to the closure directly and *loader\_details* indirectly.

If the argument to the closure is not an existing directory, `ImportError` is raised.

*class* `importlib.machinery.SourceFileLoader(fullname, path)`

A concrete implementation of `importlib.abc.SourceLoader` by subclassing `importlib.abc.FileLoader` and providing some concrete implementations of other methods.

*New in version 3.3.*

`name`

The name of the module that this loader will handle.

`path`

The path to the source file.

`is_package(fullname)`

Return `True` if `path` appears to be for a package.

`path_stats(path)`

Concrete implementation of

`importlib.abc.SourceLoader.path_stats()`.

`set_data(path, data)`

Concrete implementation of

`importlib.abc.SourceLoader.set_data()`.

`load_module(name=None)`

Concrete implementation of

`importlib.abc.Loader.load_module()` where specifying the name of the module to load is optional.

*Deprecated since version 3.6: Use*

`importlib.abc.Loader.exec_module()` instead.

`class importlib.machinery.SourcelessFileLoader(fullname, path)`

A concrete implementation of

`importlib.abc.FileLoader` which can import bytecode files (i.e. no source code files exist).

Please note that direct use of bytecode files (and thus not source code files) inhibits your modules from being usable by all Python implementations or new versions of Python which change the bytecode format.

*New in version 3.3.*

`name`

The name of the module the loader will handle.

`path`

The path to the bytecode file.

`is_package(fullname)`

Determines if the module is a package based on `path`.

`get_code(fullname)`

Returns the code object for `name` created from `path`.

`get_source(fullname)`

Returns `None` as bytecode files have no source when this loader is used.

`load_module(name=None)`

Concrete implementation of `importlib.abc.Loader.load_module()` where specifying the name of the module to load is optional.

*Deprecated since version 3.6:* Use

`importlib.abc.Loader.exec_module()` instead.

*class* `importlib.machinery.ExtensionFileLoader(fullname, path)`

A concrete implementation of `importlib.abc.ExecutionLoader` for extension modules.

The *fullname* argument specifies the name of the module the loader is to support. The *path* argument is the path to the extension module's file.

Note that, by default, importing an extension module will fail in subinterpreters if it doesn't implement multi-phase init (see [PEP 489](https://peps.python.org/pep-0489/) [https://peps.python.org/pep-0489/]), even if it would otherwise import successfully.

*New in version 3.3.*

*Changed in version 3.12:* Multi-phase init is now required for use in subinterpreters.

`name`

Name of the module the loader supports.

`path`

Path to the extension module.

`create_module(spec)`

Creates the module object from the given specification in accordance with **PEP 489** [<https://peps.python.org/pep-0489/>].

*New in version 3.5.*

`exec_module(module)`

Initializes the given module object in accordance with **PEP 489** [<https://peps.python.org/pep-0489/>].

*New in version 3.5.*

`is_package(fullname)`

Returns `True` if the file path points to a package's `__init__` module based on **EXTENSION\_SUFFIXES**.

`get_code(fullname)`

Returns `None` as extension modules lack a code object.

`get_source(fullname)`

Returns `None` as extension modules do not have source code.

`get_filename(fullname)`

Returns **path**.

*New in version 3.4.*

`NamespaceLoader(name, path, path_finder):`

A concrete implementation of `importlib.abc.InspectLoader` for namespace packages. This is an alias for a private class and is only made public for introspecting the `__loader__` attribute on namespace packages:

```
>>> from importlib.machinery import NamespaceLoader
>>> import my_namespace
>>> isinstance(my_namespace.__loader__, NamespaceLo
True
>>> import importlib.abc
>>> isinstance(my_namespace.__loader__, importlib.a
True
```

*New in version 3.11.*

```
class importlib.machinery.ModuleSpec(name, loader, *,
origin=None, loader_state=None, is_package=None)
```

A specification for a module's import-system-related state. This is typically exposed as the module's `__spec__` attribute. In the descriptions below, the names in parentheses give the corresponding attribute available directly on the module object, e.g. `module.__spec__.origin == module.__file__`. Note, however, that while the *values* are usually equivalent, they can differ since there is no synchronization between the two objects. For example, it is possible to update the module's `__file__` at runtime and this will not be automatically reflected in the module's `__spec__.origin`, and vice versa.

*New in version 3.4.*

name

(`__name__`)

The module's fully qualified name. The `finder` should always set this attribute to a non-empty string.

loader

(`__loader__`)

The `loader` used to load the module. The `finder` should always set this attribute.

`origin`

(`__file__`)

The location the `loader` should use to load the module. For example, for modules loaded from a .py file this is the filename. The `finder` should always set this attribute to a meaningful value for the `loader` to use. In the uncommon case that there is not one (like for namespace packages), it should be set to `None`.

`submodule_search_locations`

(`__path__`)

The list of locations where the package's submodules will be found. Most of the time this is a single directory. The `finder` should set this attribute to a list, even an empty one, to indicate to the import system that the module is a package. It should be set to `None` for non-package modules. It is set automatically later to a special object for namespace packages.

`loader_state`

The `finder` may set this attribute to an object containing additional, module-specific data to use when loading the module. Otherwise it should be set to `None`.

`cached`

(`__cached__`)

The filename of a compiled version of the module's code. The `finder` should always set this attribute but it may be `None` for modules that do not need compiled code stored.

parent

(`__package__`)

(Read-only) The fully qualified name of the package the module is in (or the empty string for a top-level module). If the module is a package then this is the same as `name`.

has\_location

True if the spec's `origin` refers to a loadable location, False otherwise. This value impacts how `origin` is interpreted and how the module's `__file__` is populated.

## `importlib.util` – Utility code for importers

**Source code:** [Lib/importlib/util.py](#) [<https://github.com/python/cpython/tree/3.12/Lib/importlib/util.py>]

---

This module contains the various objects that help in the construction of an `importer`.

`importlib.util.MAGIC_NUMBER`

The bytes which represent the bytecode version number. If you need help with loading/writing bytecode then consider [importlib.abc.SourceLoader](#).

*New in version 3.4.*

`importlib.util.cache_from_source(path, debug_override=None, *, optimization=None)`

Return the [PEP 3147](#) [<https://peps.python.org/pep-3147/>]/[PEP 488](#) [<https://peps.python.org/pep-0488/>] `path` to the byte-compiled file associated with the source `path`. For example, if `path` is `/foo/bar/baz.py` the return value would be `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. The

`cpython-32` string comes from the current magic tag (see `get_tag()`; if `sys.implementation.cache_tag` is not defined then `NotImplementedError` will be raised).

The *optimization* parameter is used to specify the optimization level of the bytecode file. An empty string represents no optimization, so `/foo/bar/baz.py` with an *optimization* of `''` will result in a bytecode path of `/foo/bar/__pycache__/baz.cpython-32.pyc`. `None` causes the interpreter's optimization level to be used. Any other value's string representation is used, so `/foo/bar/baz.py` with an *optimization* of `2` will lead to the bytecode path of `/foo/bar/__pycache__/baz.cpython-32.opt-2.pyc`. The string representation of *optimization* can only be alphanumeric, else `ValueError` is raised.

The *debug override* parameter is deprecated and can be used to override the system's value for `__debug__`. A `True` value is the equivalent of setting *optimization* to the empty string. A `False` value is the same as setting *optimization* to `1`. If both *debug override* and *optimization* are not `None` then `TypeError` is raised.

*New in version 3.4.*

*Changed in version 3.5:* The *optimization* parameter was added and the *debug override* parameter was deprecated.

*Changed in version 3.6:* Accepts a [path-like object](#).

`importlib.util.source_from_cache(path)`

Given the *path* to a [PEP 3147](#) [<https://peps.python.org/pep-3147/>] file name, return the associated source code file path. For example, if *path* is `/foo/bar/__pycache__/baz.cpython-32.pyc` the returned path would be `/foo/bar/baz.py`. *path* need not exist, however if it does not conform to [PEP 3147](#) [<https://peps.python.org/pep-3147/>] or [PEP 488](#) [<https://peps.python.org/pep-0488/>] format, a `ValueError` is raised. If `sys.implementation.cache_tag` is not defined, `NotImplementedError` is raised.

*New in version 3.4.*

*Changed in version 3.6:* Accepts a [path-like object](#).

`importlib.util.decode_source(source_bytes)`

Decode the given bytes representing source code and return it as a string with universal newlines (as required by `importlib.abc.InspectLoader.get_source()`).

*New in version 3.4.*

`importlib.util.resolve_name(name, package)`

Resolve a relative module name to an absolute one.

If **name** has no leading dots, then **name** is simply returned. This allows for usage such as

`importlib.util.resolve_name('sys', __spec__.parent)` without doing a check to see if the **package** argument is needed.

**ImportError** is raised if **name** is a relative module name but **package** is a false value (e.g. `None` or the empty string). **ImportError** is also raised if a relative name would escape its containing package (e.g. requesting `..bacon` from within the `spam` package).

*New in version 3.3.*

*Changed in version 3.9:* To improve consistency with import statements, raise **ImportError** instead of **ValueError** for invalid relative import attempts.

`importlib.util.find_spec(name, package=None)`

Find the [spec](#) for a module, optionally relative to the specified **package** name. If the module is in `sys.modules`, then `sys.modules[name].__spec__` is returned (unless the spec would be `None` or is not set, in which case **ValueError** is raised). Otherwise a search using `sys.meta_path` is done. `None` is returned if no spec is

found.

If **name** is for a submodule (contains a dot), the parent module is automatically imported.

**name** and **package** work the same as for **import\_module()**.

*New in version 3.4.*

*Changed in version 3.7:* Raises **ModuleNotFoundError** instead of **AttributeError** if **package** is in fact not a package (i.e. lacks a **\_\_path\_\_** attribute).

`importlib.util.module_from_spec(spec)`

Create a new module based on **spec** and **spec.loader.create\_module**.

If **spec.loader.create\_module** does not return `None`, then any pre-existing attributes will not be reset. Also, no **AttributeError** will be raised if triggered while accessing **spec** or setting an attribute on the module.

This function is preferred over using **types.ModuleType** to create a new module as **spec** is used to set as many import-controlled attributes on the module as possible.

*New in version 3.5.*

`importlib.util.spec_from_loader(name, loader, *, origin=None, is_package=None)`

A factory function for creating a **ModuleSpec** instance based on a loader. The parameters have the same meaning as they do for **ModuleSpec**. The function uses available **loader** APIs, such as **InspectLoader.is\_package()**, to fill in any missing information on the spec.

*New in version 3.4.*

`importlib.util.spec_from_file_location(name, location, *,`

*loader=None, submodule\_search\_locations=None)*

A factory function for creating a `ModuleSpec` instance based on the path to a file. Missing information will be filled in on the spec by making use of loader APIs and by the implication that the module will be file-based.

*New in version 3.4.*

*Changed in version 3.6:* Accepts a [path-like object](#).

`importlib.util.source_hash(source_bytes)`

Return the hash of `source_bytes` as bytes. A hash-based `.pyc` file embeds the `source_hash()` of the corresponding source file's contents in its header.

*New in version 3.7.*

`importlib.util.incompatible_extension_module_restrictions(*, disable_check)`

A context manager that can temporarily skip the compatibility check for extension modules. By default the check is enabled and will fail when a single-phase init module is imported in a subinterpreter. It will also fail for a multi-phase init module that doesn't explicitly support a per-interpreter GIL, when imported in an interpreter with its own GIL.

Note that this function is meant to accommodate an unusual case; one which is likely to eventually go away. There's a pretty good chance this is not what you were looking for.

You can get the same effect as this function by implementing the basic interface of multi-phase init ([PEP 489](https://peps.python.org/pep-0489/) [https://peps.python.org/pep-0489/]) and lying about support for multiple interpreters (or per-interpreter GIL).

## Warning

Using this function to disable the check can lead to

unexpected behavior and even crashes. It should only be used during extension module development.

*New in version 3.12.*

`class importlib.util.LazyLoader(loader)`

A class which postpones the execution of the loader of a module until the module has an attribute accessed.

This class **only** works with loaders that define `exec_module()` as control over what module type is used for the module is required. For those same reasons, the loader's `create_module()` method must return `None` or a type for which its `__class__` attribute can be mutated along with not using `slots`. Finally, modules which substitute the object placed into `sys.modules` will not work as there is no way to properly replace the module references throughout the interpreter safely; `ValueError` is raised if such a substitution is detected.

### Note

For projects where startup time is critical, this class allows for potentially minimizing the cost of loading a module if it is never used. For projects where startup time is not essential then use of this class is **heavily** discouraged due to error messages created during loading being postponed and thus occurring out of context.

*New in version 3.5.*

*Changed in version 3.6:* Began calling `create_module()`, removing the compatibility warning for `importlib.machinery.BuiltinImporter` and `importlib.machinery.ExtensionFileLoader`.

`classmethod factory(loader)`

A class method which returns a callable that creates a lazy loader. This is meant to be used in situations

where the loader is passed by class instead of by instance.

```
suffixes = importlib.machinery.SOURCE_SUFFIXES
loader = importlib.machinery.SourceFileLoader
lazy_loader = importlib.util.LazyLoader.factory
finder = importlib.machinery.FileFinder(path, ...)
```

## Examples

### Importing programmatically

To programmatically import a module, use

`importlib.import_module()`.

```
import importlib
```

```
itertools = importlib.import_module('itertools')
```

### Checking if a module can be imported

If you need to find out if a module can be imported without actually doing the import, then you should use

`importlib.util.find_spec()`.

Note that if `name` is a submodule (contains a dot),

`importlib.util.find_spec()` will import the parent module.

```
import importlib.util
import sys
```

```
# For illustrative purposes.
name = 'itertools'
```

```
if name in sys.modules:
    print(f"{name!r} already in sys.modules")
elif (spec := importlib.util.find_spec(name)) is not None:
    # If you chose to perform the actual import ...
    module = importlib.util.module_from_spec(spec)
```

```
sys.modules[name] = module
spec.loader.exec_module(module)
print(f"{name!r} has been imported")
else:
    print(f"can't find the {name!r} module")
```

## Importing a source file directly

To import a Python source file directly, use the following recipe:

```
import importlib.util
import sys

# For illustrative purposes.
import tokenize
file_path = tokenize.__file__
module_name = tokenize.__name__

spec = importlib.util.spec_from_file_location(module_name, file_path)
module = importlib.util.module_from_spec(spec)
sys.modules[module_name] = module
spec.loader.exec_module(module)
```

## Implementing lazy imports

The example below shows how to implement lazy imports:

```
>>> import importlib.util
>>> import sys
>>> def lazy_import(name):
...     spec = importlib.util.find_spec(name)
...     loader = importlib.util.LazyLoader(spec.loader)
...     spec.loader = loader
...     module = importlib.util.module_from_spec(spec)
...     sys.modules[name] = module
...     loader.exec_module(module)
...     return module
...
>>> lazy_typing = lazy_import("typing")
```

```
>>> #lazy_typing is a real module object,  
>>> #but it is not loaded in memory yet.  
>>> lazy_typing.TYPE_CHECKING  
False
```

## Setting up an importer

For deep customizations of import, you typically want to implement an [importer](#). This means managing both the [finder](#) and [loader](#) side of things. For finders there are two flavours to choose from depending on your needs: a [meta path finder](#) or a [path entry finder](#). The former is what you would put on [sys.meta\\_path](#) while the latter is what you create using a [path entry hook](#) on [sys.path\\_hooks](#) which works with [sys.path](#) entries to potentially create a finder. This example will show you how to register your own importers so that import will use them (for creating an importer for yourself, read the documentation for the appropriate classes defined within this package):

```
import importlib.machinery  
import sys  
  
# For illustrative purposes only.  
SpamMetaPathFinder = importlib.machinery.PathFinder  
SpamPathEntryFinder = importlib.machinery.FileFinder  
loader_details = (importlib.machinery.SourceFileLoader,  
                  importlib.machinery.SOURCE_SUFFIXES)  
  
# Setting up a meta path finder.  
# Make sure to put the finder in the proper location in  
# priority.  
sys.meta_path.append(SpamMetaPathFinder)  
  
# Setting up a path entry finder.  
# Make sure to put the path hook in the proper location  
# of priority.  
sys.path_hooks.append(SpamPathEntryFinder.path_hook(loader_details))
```

## Approximating [importlib.import\\_module\(\)](#)

Import itself is implemented in Python code, making it possible to expose most of the import machinery through importlib. The following helps illustrate the various APIs that importlib exposes by providing an approximate implementation of

`importlib.import_module()`:

```
import importlib.util
import sys
```

```
def import_module(name, package=None):
    """An approximate implementation of import."""
    absolute_name = importlib.util.resolve_name(name, package)
    try:
        return sys.modules[absolute_name]
    except KeyError:
        pass

    path = None
    if '.' in absolute_name:
        parent_name, _, child_name = absolute_name.rpartition('.')
        parent_module = import_module(parent_name)
        path = parent_module.__spec__.submodule_search_locations
    for finder in sys.meta_path:
        spec = finder.find_spec(absolute_name, path)
        if spec is not None:
            break
    else:
        msg = f'No module named {absolute_name!r}'
        raise ModuleNotFoundError(msg, name=absolute_name)
    module = importlib.util.module_from_spec(spec)
    sys.modules[absolute_name] = module
    spec.loader.exec_module(module)
    if path is not None:
        setattr(parent_module, child_name, module)
    return module
```

# `importlib.resources` – Package resource reading, opening and access

**Source code:** [Lib/importlib/resources/\\_init\\_.py](https://github.com/python/cpython/tree/3.12/Lib/importlib/resources/_init_.py) [https://github.com/python/cpython/tree/3.12/Lib/importlib/resources/\_init\_.py]

---

*New in version 3.7.*

This module leverages Python’s import system to provide access to *resources* within *packages*.

“Resources” are file-like resources associated with a module or package in Python. The resources may be contained directly in a package, within a subdirectory contained in that package, or adjacent to modules outside a package. Resources may be text or binary. As a result, Python module sources (.py) of a package and compilation artifacts (pycache) are technically de-facto resources of that package. In practice, however, resources are primarily those non-Python artifacts exposed specifically by the package author.

Resources can be opened or read in either binary or text mode.

Resources are roughly akin to files inside directories, though it’s important to keep in mind that this is just a metaphor. Resources and packages **do not** have to exist as physical files and directories on the file system: for example, a package and its resources can be imported from a zip file using `zipimport`.

## Note

This module provides functionality similar to [pkg\\_resources](https://setuptools.readthedocs.io/en/latest/pkg_resources.html) [https://setuptools.readthedocs.io/en/latest/pkg\_resources.html] [Basic Resource Access](#) [https://setuptools.readthedocs.io/en/latest/

`pkg_resources.html#basic-resource-access]` without the performance overhead of that package. This makes reading resources included in packages easier, with more stable and consistent semantics.

The standalone backport of this module provides more information on [using `importlib.resources`](https://importlib-resources.readthedocs.io/en/latest/using.html) [https://importlib-resources.readthedocs.io/en/latest/using.html] and [migrating from `pkg\_resources` to `importlib.resources`](https://importlib-resources.readthedocs.io/en/latest/migration.html) [https://importlib-resources.readthedocs.io/en/latest/migration.html].

**Loaders** that wish to support resource reading should implement a `get_resource_reader(fullname)` method as specified by [`importlib.resources.abc.ResourceReader`](#).

`importlib.resources.Anchor`

Represents an anchor for resources, either a [`module object`](#) or a module name as a string. Defined as `Union[str, ModuleType]`.

`importlib.resources.files(anchor: Optional[Anchor] = None)`

Returns a [`Traversable`](#) object representing the resource container (think directory) and its resources (think files). A `Traversable` may contain other containers (think subdirectories).

*anchor* is an optional [`Anchor`](#). If the anchor is a package, resources are resolved from that package. If a module, resources are resolved adjacent to that module (in the same package or the package root). If the anchor is omitted, the caller's module is used.

*New in version 3.9.*

*Changed in version 3.12:* “package” parameter was renamed to “anchor”. “anchor” can now be a non-package module and if omitted will default to the caller's module. “package” is still accepted for compatibility but will raise a `DeprecationWarning`. Consider passing the anchor positionally or using `importlib_resources >= 5.10` for a compatible interface on older Pythons.

`importlib.resources.as_file(traversable)`

Given a **Traversable** object representing a file or directory, typically from `importlib.resources.files()`, return a context manager for use in a **with** statement. The context manager provides a **pathlib.Path** object.

Exiting the context manager cleans up any temporary file or directory created when the resource was extracted from e.g. a zip file.

Use `as_file` when the Traversable methods (`read_text`, etc) are insufficient and an actual file or directory on the file system is required.

*New in version 3.9.*

*Changed in version 3.12:* Added support for `traversable` representing a directory.

## Deprecated functions

An older, deprecated set of functions is still available, but is scheduled for removal in a future version of Python. The main drawback of these functions is that they do not support directories: they assume all resources are located directly within a *package*.

`importlib.resources.Package`

Whenever a function accepts a `Package` argument, you can pass in either a **module object** or a module name as a string. You can only pass module objects whose `__spec__.submodule_search_locations` is not `None`.

The `Package` type is defined as `Union[str, ModuleType]`.

*Deprecated since version 3.12.*

`importlib.resources.Resource`

For *resource* arguments of the functions below, you can pass in the name of a resource as a string or a **path-like object**.

The `Resource` type is defined as `Union[str, os.PathLike]`.

`importlib.resources.open_binary(package, resource)`

Open for binary reading the *resource* within *package*.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). This function returns a `typing.BinaryIO` instance, a binary I/O stream open for reading.

*Deprecated since version 3.11:* Calls to this function can be replaced by:

```
files(package).joinpath(resource).open('rb')
```

`importlib.resources.open_text(package, resource, encoding='utf-8', errors='strict')`

Open for text reading the *resource* within *package*. By default, the resource is opened for reading as UTF-8.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). *encoding* and *errors* have the same meaning as with built-in **`open()`**.

This function returns a `typing.TextIO` instance, a text I/O stream open for reading.

*Deprecated since version 3.11:* Calls to this function can be replaced by:

```
files(package).joinpath(resource).open('r', encoding=
```

```
importlib.resources.read_binary(package, resource)
```

Read and return the contents of the *resource* within *package* as bytes.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). This function returns the contents of the resource as **bytes**.

*Deprecated since version 3.11:* Calls to this function can be replaced by:

```
files(package).joinpath(resource).read_bytes()
```

```
importlib.resources.read_text(package, resource, encoding='utf-8',  
errors='strict')
```

Read and return the contents of *resource* within *package* as a `str`. By default, the contents are read as strict UTF-8.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). *encoding* and *errors* have the same meaning as with built-in **`open()`**. This function returns the contents of the resource as **str**.

*Deprecated since version 3.11:* Calls to this function can be replaced by:

```
files(package).joinpath(resource).read_text(encoding=
```

```
importlib.resources.path(package, resource)
```

Return the path to the *resource* as an actual file system path. This function returns a context manager for use in a **with**

statement. The context manager provides a `pathlib.Path` object.

Exiting the context manager cleans up any temporary file created when the resource needs to be extracted from e.g. a zip file.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory).

*Deprecated since version 3.11:* Calls to this function can be replaced using `as_file()`:

```
as_file(files(package).joinpath(resource))
```

`importlib.resources.is_resource(package, name)`

Return `True` if there is a resource named *name* in the package, otherwise `False`. This function does not consider directories to be resources. *package* is either a name or a module object which conforms to the `Package` requirements.

*Deprecated since version 3.11:* Calls to this function can be replaced by:

```
files(package).joinpath(resource).is_file()
```

`importlib.resources.contents(package)`

Return an iterable over the named items within the package. The iterable returns `str` resources (e.g. files) and non-resources (e.g. directories). The iterable does not recurse into subdirectories.

*package* is either a name or a module object which conforms to the `Package` requirements.

*Deprecated since version 3.11:* Calls to this function can be

replaced by:

```
(resource.name for resource in files(package).iterd
```

# `importlib.resources.abc` – Abstract base classes for resources

**Source code:** [Lib/importlib/resources/abc.py](https://github.com/python/cpython/tree/3.12/Lib/importlib/resources/abc.py) [https://github.com/python/cpython/tree/3.12/Lib/importlib/resources/abc.py]

---

*New in version 3.11.*

`class importlib.resources.abc.ResourceReader`

*Superseded by `TraversableResources`*

An [abstract base class](#) to provide the ability to read *resources*.

From the perspective of this ABC, a *resource* is a binary artifact that is shipped within a package. Typically this is something like a data file that lives next to the `__init__.py` file of the package. The purpose of this class is to help abstract out the accessing of such data files so that it does not matter if the package and its data file(s) are stored in a e.g. zip file versus on the file system.

For any of methods of this class, a *resource* argument is expected to be a [path-like object](#) which represents conceptually just a file name. This means that no subdirectory paths should be included in the *resource* argument. This is because the location of the package the reader is for, acts as the “directory”. Hence the metaphor for directories and file names is packages and resources, respectively. This is also why instances of this class are expected to directly correlate to a specific package (instead of potentially representing multiple packages or a module).

Loaders that wish to support resource reading are expected to

provide a method called

`get_resource_reader(fullname)` which returns an object implementing this ABC's interface. If the module specified by `fullname` is not a package, this method should return **None**. An object compatible with this ABC should only be returned when the specified module is a package.

*Deprecated since version 3.12, will be removed in version 3.14:*

Use

**`importlib.resources.abc.TraversableResources`** instead.

*abstractmethod* `open_resource(resource)`

Returns an opened, **file-like object** for binary reading of the *resource*.

If the resource cannot be found, **`FileNotFoundError`** is raised.

*abstractmethod* `resource_path(resource)`

Returns the file system path to the *resource*.

If the resource does not concretely exist on the file system, raise **`FileNotFoundError`**.

*abstractmethod* `is_resource(name)`

Returns **True** if the named *name* is considered a resource. **`FileNotFoundError`** is raised if *name* does not exist.

*abstractmethod* `contents()`

Returns an **iterable** of strings over the contents of the package. Do note that it is not required that all names returned by the iterator be actual resources, e.g. it is acceptable to return names for which **`is_resource()`** would be false.

Allowing non-resource names to be returned is to allow for situations where how a package and its resources

are stored are known a priori and the non-resource names would be useful. For instance, returning subdirectory names is allowed so that when it is known that the package and resources are stored on the file system then those subdirectory names can be used directly.

The abstract method returns an iterable of no items.

*class* `importlib.resources.abc.Traversable`

An object with a subset of `pathlib.Path` methods suitable for traversing directories and opening files.

For a representation of the object on the file-system, use `importlib.resources.as_file()`.

*name*

Abstract. The base name of this object without any parent references.

*abstractmethod* `iterdir()`

Yield Traversable objects in self.

*abstractmethod* `is_dir()`

Return True if self is a directory.

*abstractmethod* `is_file()`

Return True if self is a file.

*abstractmethod* `joinpath(child)`

Return Traversable child in self.

*abstractmethod* `_truediv_(child)`

Return Traversable child in self.

*abstractmethod* `open(mode='r', *args, **kwargs)`

*mode* may be 'r' or 'rb' to open as text or binary. Return a handle suitable for reading (same as `pathlib.Path.open`).

When opening as text, accepts encoding parameters such as those accepted by `io.TextIOWrapper`.

`read_bytes()`

Read contents of self as bytes.

`read_text(encoding=None)`

Read contents of self as text.

*class* `importlib.resources.abc.TraversableResources`

An abstract base class for resource readers capable of serving the `importlib.resources.files()` interface. Subclasses `ResourceReader` and provides concrete implementations of the `ResourceReader`'s abstract methods. Therefore, any loader supplying `TraversableResources` also supplies `ResourceReader`.

Loaders that wish to support resource reading are expected to implement this interface.

*abstractmethod* `files()`

Returns a

`importlib.resources.abc.Traversable` object for the loaded package.

# importlib.metadata – Accessing package metadata

*New in version 3.8.*

*Changed in version 3.10:* `importlib.metadata` is no longer provisional.

**Source code:** [Lib/importlib/metadata/\\_init\\_.py](https://github.com/python/cpython/tree/3.12/Lib/importlib/metadata/_init_.py) [https://github.com/python/cpython/tree/3.12/Lib/importlib/metadata/\_init\_.py]

`importlib.metadata` is a library that provides access to the metadata of an installed [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package], such as its entry points or its top-level names ([Import Package](https://packaging.python.org/en/latest/glossary/#term-Import-Package) [https://packaging.python.org/en/latest/glossary/#term-Import-Package]s, modules, if any). Built in part on Python’s import system, this library intends to replace similar functionality in the [entry point API](https://setuptools.readthedocs.io/en/latest/pkg_resources.html#entry-points) [https://setuptools.readthedocs.io/en/latest/pkg\_resources.html#entry-points] and [metadata API](https://setuptools.readthedocs.io/en/latest/pkg_resources.html#metadata-api) [https://setuptools.readthedocs.io/en/latest/pkg\_resources.html#metadata-api] of `pkg_resources`. Along with [importlib.resources](#), this package can eliminate the need to use the older and less efficient `pkg_resources` package.

`importlib.metadata` operates on third-party *distribution packages* installed into Python’s `site-packages` directory via tools such as [pip](https://pypi.org/project/pip/) [https://pypi.org/project/pip/]. Specifically, it works with distributions with discoverable `dist-info` or `egg-info` directories, and metadata defined by the [Core metadata specifications](https://packaging.python.org/en/latest/specifications/core-metadata/#core-metadata) [https://packaging.python.org/en/latest/specifications/core-metadata/#core-metadata].

## Important

These are *not* necessarily equivalent to or correspond 1:1 with the top-level *import package* names that can be imported inside

Python code. One *distribution package* can contain multiple *import packages* (and single modules), and one top-level *import package* may map to multiple *distribution packages* if it is a namespace package. You can use `package_distributions()` to get a mapping between them.

By default, distribution metadata can live on the file system or in zip archives on `sys.path`. Through an extension mechanism, the metadata can live almost anywhere.

The documentation for `importlib_metadata`, which supplies a backport of `importlib.metadata`. This includes an [API reference](https://importlib-metadata.readthedocs.io/en/latest/api.html) [https://importlib-metadata.readthedocs.io/en/latest/api.html] for this module's classes and functions, as well as a [migration guide](https://importlib-metadata.readthedocs.io/en/latest/migration.html) [https://importlib-metadata.readthedocs.io/en/latest/migration.html] for existing users of `pkg_resources`.

## Overview

Let's say you wanted to get the version string for a [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] you've installed using `pip`. We start by creating a virtual environment and installing something into it:

```
$ python -m venv example
$ source example/bin/activate
(example) $ python -m pip install wheel
```

You can get the version string for `wheel` by running the following:

```
(example) $ python
>>> from importlib.metadata import version
>>> version('wheel')
'0.32.3'
```

You can also get a collection of entry points selectable by properties of the `EntryPoint` (typically ‘group’ or ‘name’), such as `console_scripts`, `distutils.commands` and others. Each group contains a collection of [EntryPoint](#) objects.

You can get the [metadata for a distribution](#):

```
>>> list(metadata('wheel'))
['Metadata-Version', 'Name', 'Version', 'Summary', 'Home
```

You can also get a [distribution’s version number](#), list its [constituent files](#), and get a list of the distribution’s [Distribution requirements](#).

## Functional API

This package provides the following functionality via its public API.

### Entry points

The `entry_points()` function returns a collection of entry points. Entry points are represented by `EntryPoint` instances; each `EntryPoint` has a `.name`, `.group`, and `.value` attributes and a `.load()` method to resolve the value. There are also `.module`, `.attr`, and `.extras` attributes for getting the components of the `.value` attribute.

Query all entry points:

```
>>> eps = entry_points()
```

The `entry_points()` function returns an `EntryPoints` object, a collection of all `EntryPoint` objects with names and groups attributes for convenience:

```
>>> sorted(eps.groups)
['console_scripts', 'distutils.commands', 'distutils.set
```

`EntryPoints` has a `select` method to select entry points matching specific properties. Select entry points in the `console_scripts` group:

```
>>> scripts = eps.select(group='console_scripts')
```

Equivalently, since `entry_points` passes keyword arguments through to `select`:

```
>>> scripts = entry_points(group='console_scripts')
```

Pick out a specific script named “wheel” (found in the wheel project):

```
>>> 'wheel' in scripts.names
True
>>> wheel = scripts['wheel']
```

Equivalently, query for that entry point during selection:

```
>>> (wheel,) = entry_points(group='console_scripts', name='wheel')
>>> (wheel,) = entry_points().select(group='console_scripts', name='wheel')
```

Inspect the resolved entry point:

```
>>> wheel
EntryPoint(name='wheel', value='wheel.cli:main', group='console_scripts')
>>> wheel.module
'wheel.cli'
>>> wheel.attr
'main'
>>> wheel.extras
[]
>>> main = wheel.load()
>>> main
<function main at 0x103528488>
```

The `group` and `name` are arbitrary values defined by the package author and usually a client will wish to resolve all entry points for a particular group. Read [the `setuptools` docs](https://setuptools.pypa.io/en/latest/userguide/entry_point.html) [https://setuptools.pypa.io/en/latest/userguide/entry\_point.html] for more information on entry points, their definition, and usage.

*Compatibility Note*

The “selectable” entry points were introduced in `importlib_metadata` 3.6 and Python 3.10. Prior to those changes, `entry_points` accepted no parameters and always returned a dictionary of entry points, keyed by group. With `importlib_metadata` 5.0 and Python 3.12, `entry_points` always returns an `EntryPoint` object. See [backports.entry\\_points\\_selectable](https://pypi.org/project/backports.entry-points-selectable) [https://pypi.org/project/backports.entry-points-selectable] for compatibility options.

## Distribution metadata

Every [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] includes some metadata, which you can extract using the `metadata()` function:

```
>>> wheel_metadata = metadata('wheel')
```

The keys of the returned data structure, a `PackageMetadata`, name the metadata keywords, and the values are returned unparsed from the distribution metadata:

```
>>> wheel_metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
```

`PackageMetadata` also presents a `json` attribute that returns all the metadata in a JSON-compatible form per [PEP 566](https://peps.python.org/pep-0566/) [https://peps.python.org/pep-0566/]:

```
>>> wheel_metadata.json['requires_python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
```

### Note

The actual type of the object returned by `metadata()` is an implementation detail and should be accessed only through the interface described by the [PackageMetadata protocol](https://importlib-metadata.readthedocs.io/en/latest/api.html#importlib_metadata.PackageMetadata) [https://importlib-metadata.readthedocs.io/en/latest/api.html#importlib\_metadata.PackageMetadata].

*Changed in version 3.10:* The `Description` is now included in the

metadata when presented through the payload. Line continuation characters have been removed.

*New in version 3.10:* The `json` attribute was added.

## Distribution versions

The `version()` function is the quickest way to get a [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package]’s version number, as a string:

```
>>> version('wheel')
'0.32.3'
```

## Distribution files

You can also get the full set of files contained within a distribution. The `files()` function takes a [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] name and returns all of the files installed by this distribution. Each file object returned is a `PackagePath`, a [pathlib.PurePath](#) derived object with additional `dist`, `size`, and `hash` properties as indicated by the metadata. For example:

```
>>> util = [p for p in files('wheel') if 'util.py' in str(p)]
>>> util
PackagePath('wheel/util.py')
>>> util.size
859
>>> util.dist
<importlib.metadata._hooks.PathDistribution object at 0x...>
>>> util.hash
<FileHash mode: sha256 value: bYkw5oMccfazVCoYQwKkkemoVy...
```

Once you have the file, you can also read its contents:

```
>>> print(util.read_text())
import base64
import sys
...
```

```
def as_bytes(s):
    if isinstance(s, text_type):
        return s.encode('utf-8')
    return s
```

You can also use the `locate` method to get a the absolute path to the file:

```
>>> util.locate()
PosixPath('/home/gustav/example/lib/site-packages/wheel/')
```

In the case where the metadata file listing files (RECORD or SOURCES.txt) is missing, `files()` will return `None`. The caller may wish to wrap calls to `files()` in [always\\_iterable](https://more-itertools.readthedocs.io/en/stable/api.html#more_itertools.always_iterable) [https://more-itertools.readthedocs.io/en/stable/api.html#more\_itertools.always\_iterable] OR otherwise guard against this condition if the target distribution is not known to have the metadata present.

## Distribution requirements

To get the full set of requirements for a [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package], use the `requires()` function:

```
>>> requires('wheel')
["pytest (>=3.0.0) ; extra == 'test'", "pytest-cov ; ext
```

## Mapping import to distribution packages

A convenience method to resolve the [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] name (or names, in the case of a namespace package) that provide each importable top-level Python module or [Import Package](https://packaging.python.org/en/latest/glossary/#term-Import-Package) [https://packaging.python.org/en/latest/glossary/#term-Import-Package]:

```
>>> packages_distributions()
{'importlib_metadata': ['importlib-metadata'], 'yaml': [
```

Some editable installs, [do not supply top-level names](https://github.com/pypa/packaging-problems/issues/609) [https://github.com/pypa/packaging-problems/issues/609], and thus this function is

not reliable with such installs.

*New in version 3.10.*

## Distributions

While the above API is the most common and convenient usage, you can get all of that information from the `Distribution` class. A `Distribution` is an abstract object that represents the metadata for a Python [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package]. You can get the `Distribution` instance:

```
>>> from importlib.metadata import distribution
>>> dist = distribution('wheel')
```

Thus, an alternative way to get the version number is through the `Distribution` instance:

```
>>> dist.version
'0.32.3'
```

There are all kinds of additional metadata available on the `Distribution` instance:

```
>>> dist.metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
>>> dist.metadata['License']
'MIT'
```

The full set of available metadata is not described here. See the [Core metadata specifications](https://packaging.python.org/en/latest/specifications/core-metadata/#core-metadata) [https://packaging.python.org/en/latest/specifications/core-metadata/#core-metadata] for additional details.

## Distribution Discovery

By default, this package provides built-in support for discovery of metadata for file system and zip file [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package]s. This metadata finder search defaults to `sys.path`, but varies slightly in

how it interprets those values from how other import machinery does. In particular:

- `importlib.metadata` does not honor `bytes` objects on `sys.path`.
- `importlib.metadata` will incidentally honor `pathlib.Path` objects on `sys.path` even though such values will be ignored for imports.

## Extending the search algorithm

Because [Distribution Package](https://packaging.python.org/en/latest/glossary/#term-Distribution-Package) [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] `metadata` is not available through `sys.path` searches, or package loaders directly, the `metadata` for a distribution is found through import system `finders`. To find a distribution package's `metadata`, `importlib.metadata` queries the list of `meta path finders` on `sys.meta_path`.

By default `importlib.metadata` installs a finder for distribution packages found on the file system. This finder doesn't actually find any *distributions*, but it can find their `metadata`.

The abstract class `importlib.abc.MetaPathFinder` defines the interface expected of finders by Python's import system.

`importlib.metadata` extends this protocol by looking for an optional `find_distributions` callable on the finders from `sys.meta_path` and presents this extended interface as the `DistributionFinder` abstract base class, which defines this abstract method:

```
@abc.abstractmethod
def find_distributions(context=DistributionFinder.Context):
    """Return an iterable of all Distribution instances
    loading the metadata for packages for the indicated
    """
```

The `DistributionFinder.Context` object provides `.path` and `.name` properties indicating the path to search and name to match and may supply other relevant context.

What this means in practice is that to support finding distribution package metadata in locations other than the file system, subclass `Distribution` and implement the abstract methods. Then from a custom finder, return instances of this derived `Distribution` in the `find_distributions()` method.

# The initialization of the `sys.path` module search path

A module search path is initialized when Python starts. This module search path may be accessed at `sys.path`.

The first entry in the module search path is the directory that contains the input script, if there is one. Otherwise, the first entry is the current directory, which is the case when executing the interactive shell, a `-c` command, or `-m` module.

The `PYTHONPATH` environment variable is often used to add directories to the search path. If this environment variable is found then the contents are added to the module search path.

## Note

`PYTHONPATH` will affect all installed Python versions/environments. Be wary of setting this in your shell profile or global environment variables. The `site` module offers more nuanced techniques as mentioned below.

The next items added are the directories containing standard Python modules as well as any `extension modules` that these modules depend on. Extension modules are `.pyd` files on Windows and `.so` files on other platforms. The directory with the platform-independent Python modules is called `prefix`. The directory with the extension modules is called `exec_prefix`.

The `PYTHONHOME` environment variable may be used to set the `prefix` and `exec_prefix` locations. Otherwise these directories are found by using the Python executable as a starting point and then looking for various ‘landmark’ files and directories. Note that any symbolic links are followed so the real Python executable location is used as the search starting point. The Python executable

location is called `home`.

Once `home` is determined, the `prefix` directory is found by first looking for `pythonmajorversionminorversion.zip` (`python311.zip`). On Windows the zip archive is searched for in `home` and on Unix the archive is expected to be in `lib`. Note that the expected zip archive location is added to the module search path even if the archive does not exist. If no archive was found, Python on Windows will continue the search for `prefix` by looking for `Lib\os.py`. Python on Unix will look for `lib/pythonmajorversion.minorversion/os.py` (`lib/python3.11/os.py`). On Windows `prefix` and `exec_prefix` are the same, however on other platforms `lib/pythonmajorversion.minorversion/lib-dynload` (`lib/python3.11/lib-dynload`) is searched for and used as an anchor for `exec_prefix`. On some platforms `lib` may be `lib64` or another value, see [sys.platlibdir](#) and [PYTHONPLATLIBDIR](#).

Once found, `prefix` and `exec_prefix` are available at [sys.prefix](#) and [sys.exec\\_prefix](#) respectively.

Finally, the [site](#) module is processed and `site-packages` directories are added to the module search path. A common way to customize the search path is to create [sitecustomize](#) or [usercustomize](#) modules as described in the [site](#) module documentation.

### Note

Certain command line options may further affect path calculations. See [-E](#), [-I](#), [-s](#) and [-S](#) for further details.

## Virtual environments

If Python is run in a virtual environment (as described at [Virtual Environments and Packages](#)) then `prefix` and `exec_prefix` are specific to the virtual environment.

If a `pyvenv.cfg` file is found alongside the main executable, or in the directory one level above the executable, the following variations apply:

- If `home` is an absolute path and `PYTHONHOME` is not set, this path is used instead of the path to the main executable when deducing `prefix` and `exec_prefix`.

## **`_pth` files**

To completely override `sys.path` create a `._pth` file with the same name as the shared library or executable (`python._pth` or `python311._pth`). The shared library path is always known on Windows, however it may not be available on other platforms. In the `._pth` file specify one line for each path to add to `sys.path`. The file based on the shared library name overrides the one based on the executable, which allows paths to be restricted for any program loading the runtime if desired.

When the file exists, all registry and environment variables are ignored, isolated mode is enabled, and `site` is not imported unless one line in the file specifies `import site`. Blank paths and lines starting with `#` are ignored. Each path may be absolute or relative to the location of the file. Import statements other than to `site` are not permitted, and arbitrary code cannot be specified.

Note that `.pth` files (without leading underscore) will be processed normally by the `site` module when `import site` has been specified.

## **Embedded Python**

If Python is embedded within another application `Py_InitializeFromConfig()` and the `PyConfig` structure can be used to initialize Python. The path specific details are described at [Python Path Configuration](#). Alternatively the older `Py_SetPath()` can be used to bypass the initialization of the module search path.

## See also

- [Finding modules](#) for detailed Windows notes.
- [Using Python on Unix platforms](#) for Unix details.

# Python Language Services

Python provides a number of modules to assist in working with the Python language. These modules support tokenizing, parsing, syntax analysis, bytecode disassembly, and various other facilities.

These modules include:

- **ast** — Abstract Syntax Trees
  - Abstract Grammar
  - Node classes
    - Root nodes
    - Literals
    - Variables
    - Expressions
      - Subscripting
      - Comprehensions
    - Statements
      - Imports
    - Control flow
    - Pattern matching
    - Type parameters
    - Function and class definitions
    - Async and await
  - **ast** Helpers
  - Compiler Flags
  - Command-Line Usage
- **symtable** — Access to the compiler's symbol tables
  - Generating Symbol Tables

- Examining Symbol Tables
- **token** — Constants used with Python parse trees
- **keyword** — Testing for Python keywords
- **tokenize** — Tokenizer for Python source
  - Tokenizing Input
  - Command-Line Usage
  - Examples
- **tabnanny** — Detection of ambiguous indentation
- **pyclbr** — Python module browser support
  - Function Objects
  - Class Objects
- **py\_compile** — Compile Python source files
  - Command-Line Interface
- **compileall** — Byte-compile Python libraries
  - Command-line use
  - Public functions
- **dis** — Disassembler for Python bytecode
  - Command-line interface
  - Bytecode analysis
  - Analysis functions
  - Python Bytecode Instructions
  - Opcode collections
- **pickletools** — Tools for pickle developers
  - Command line usage
    - Command line options
  - Programmatic Interface

}

```

## Node classes

*class ast.AST*

This is the base of all AST node classes. The actual node classes are derived from the `Parser/Python.asdl` file, which is reproduced [above](#). They are defined in the `_ast` C module and re-exported in `ast`.

There is one class defined for each left-hand side symbol in the abstract grammar (for example, `ast.stmt` or `ast.expr`). In addition, there is one class defined for each constructor on the right-hand side; these classes inherit from

the classes for the left-hand side trees. For example, `ast.BinOp` inherits from `ast.expr`. For production rules with alternatives (aka “sums”), the left-hand side class is abstract: only instances of specific constructor nodes are ever created.

## `_fields`

Each concrete class has an attribute `_fields` which gives the names of all child nodes.

Each instance of a concrete class has one attribute for each child node, of the type as defined in the grammar. For example, `ast.BinOp` instances have an attribute `left` of type `ast.expr`.

If these attributes are marked as optional in the grammar (using a question mark), the value might be `None`. If the attributes can have zero-or-more values (marked with an asterisk), the values are represented as Python lists. All possible attributes must be present and have valid values when compiling an AST with `compile()`.

## `lineno`

### `col_offset`

### `end_lineno`

### `end_col_offset`

Instances of `ast.expr` and `ast.stmt` subclasses have `lineno`, `col_offset`, `end_lineno`, and `end_col_offset` attributes. The `lineno` and `end_lineno` are the first and last line numbers of source text span (1-indexed so the first line is line 1) and the `col_offset` and `end_col_offset` are the corresponding UTF-8 byte offsets of the first and last tokens that generated the node. The UTF-8 offset is recorded because the parser uses UTF-8 internally.

Note that the end positions are not required by the

compiler and are therefore optional. The end offset is *after* the last symbol, for example one can get the source segment of a one-line expression node using `source_line[node.col_offset : node.end_col_offset]`.

The constructor of a class **`ast.T`** parses its arguments as follows:

- If there are positional arguments, there must be as many as there are items in **`T._fields`**; they will be assigned as attributes of these names.
- If there are keyword arguments, they will set the attributes of the same names to the given values.

For example, to create and populate an **`ast.UnaryOp`** node, you could use

```
node = ast.UnaryOp()
node.op = ast.USub()
node.operand = ast.Constant()
node.operand.value = 5
node.operand.lineno = 0
node.operand.col_offset = 0
node.lineno = 0
node.col_offset = 0
```

or the more compact

```
node = ast.UnaryOp(ast.USub(), ast.Constant(5, lineno=0, col_offset=0))
```

*Changed in version 3.8:* Class **`ast.Constant`** is now used for all constants.

*Changed in version 3.9:* Simple indices are represented by their value, extended slices are represented as tuples.

*Deprecated since version 3.8:* Old classes **`ast.Num`**, **`ast.Str`**, **`ast.Bytes`**, **`ast.NameConstant`** and **`ast.Ellipsis`** are still available, but they will be removed in future Python releases. In the

meantime, instantiating them will return an instance of a different class.

*Deprecated since version 3.9:* Old classes `ast.Index` and `ast.ExtSlice` are still available, but they will be removed in future Python releases. In the meantime, instantiating them will return an instance of a different class.

## Note

The descriptions of the specific node classes displayed here were initially adapted from the fantastic [Green Tree Snakes](https://greentreesnakes.readthedocs.io/en/latest/) [https://greentreesnakes.readthedocs.io/en/latest/] project and all its contributors.

## Root nodes

*class* `ast.Module(body, type_ignores)`

A Python module, as with [file input](#). Node type generated by `ast.parse()` in the default "exec" mode.

*body* is a [list](#) of the module's [Statements](#).

*type\_ignores* is a [list](#) of the module's type ignore comments; see `ast.parse()` for more details.

```
>>> print(ast.dump(ast.parse('x = 1'), indent=4))
Module(
  body=[
    Assign(
      targets=[
        Name(id='x', ctx=Store())],
      value=Constant(value=1)),
  type_ignores=[])
```

*class* `ast.Expression(body)`

A single Python [expression input](#). Node type generated by `ast.parse()` when *mode* is "eval".

*body* is a single node, one of the [expression types](#).

```
>>> print(ast.dump(ast.parse('123', mode='eval'), i
Expression(
    body=Constant(value=123))
```

*class ast.Interactive(*body*)*

A single [interactive input](#), like in [Interactive Mode](#). Node type generated by [ast.parse\(\)](#) when *mode* is "single".

*body* is a [list](#) of [statement nodes](#).

```
>>> print(ast.dump(ast.parse('x = 1; y = 2', mode='
Interactive(
    body=[
        Assign(
            targets=[
                Name(id='x', ctx=Store())],
            value=Constant(value=1)),
        Assign(
            targets=[
                Name(id='y', ctx=Store())],
            value=Constant(value=2))])
```

*class ast.FunctionType(*argtypes*, *returns*)*

A representation of an old-style type comments for functions, as Python versions prior to 3.5 didn't support [PEP 484](#)

[<https://peps.python.org/pep-0484/>] annotations. Node type generated by [ast.parse\(\)](#) when *mode* is "func\_type".

Such type comments would look like this:

```
def sum_two_number(a, b):
    # type: (int, int) -> int
    return a + b
```

*argtypes* is a [list](#) of [expression nodes](#).

*returns* is a single [expression node](#).

```
>>> print(ast.dump(ast.parse('(int, str) -> List[int, str]',
FunctionType(
    argtypes=[
        Name(id='int', ctx=Load()),
        Name(id='str', ctx=Load())],
    returns=Subscript(
        value=Name(id='List', ctx=Load()),
        slice=Name(id='int', ctx=Load()),
        ctx=Load()))))
```

*New in version 3.8.*

## Literals

*class* ast.Constant(*value*)

A constant value. The `value` attribute of the `Constant` literal contains the Python object it represents. The values represented can be simple types such as a number, string or `None`, but also immutable container types (tuples and frozensets) if all of their elements are constant.

```
>>> print(ast.dump(ast.parse('123', mode='eval'), include_whitespace=True))
Expression(
    body=Constant(value=123))
```

*class* ast.FormattedValue(*value, conversion, format\_spec*)

Node representing a single formatting field in an f-string. If the string contains a single formatting field and nothing else the node can be isolated otherwise it appears in [JoinedStr](#).

- `value` is any expression node (such as a literal, a variable, or a function call).
- `conversion` is an integer:
  - -1: no formatting
  - 115: `!s` string formatting
  - 114: `!r` repr formatting
  - 97: `!a` ascii formatting
- `format_spec` is a [JoinedStr](#) node representing the formatting of the value, or `None` if no format was

specified. Both `conversion` and `format_spec` can be set at the same time.

*class* `ast.JoinedStr(values)`

An f-string, comprising a series of **FormattedValue** and **Constant** nodes.

```
>>> print(ast.dump(ast.parse('f"sin({a}) is {sin(a)
Expression(
  body=JoinedStr(
    values=[
      Constant(value='sin('),
      FormattedValue(
        value=Name(id='a', ctx=Load()),
        conversion=-1),
      Constant(value=') is '),
      FormattedValue(
        value=Call(
          func=Name(id='sin', ctx=Load()),
          args=[
            Name(id='a', ctx=Load())],
          keywords=[]),
        conversion=-1,
        format_spec=JoinedStr(
          values=[
            Constant(value='.3')]))]))))
```

*class* `ast.List(elts, ctx)`

*class* `ast.Tuple(elts, ctx)`

A list or tuple. `elts` holds a list of nodes representing the elements. `ctx` is **Store** if the container is an assignment target (i.e. `(x,y)=something`), and **Load** otherwise.

```
>>> print(ast.dump(ast.parse('[1, 2, 3]', mode='eval')
Expression(
  body=List(
    elts=[
      Constant(value=1),
```

```

        Constant (value=2),
        Constant (value=3)],
    ctx=Load())
>>> print(ast.dump(ast.parse('(1, 2, 3)', mode='eval'),
Expression(
    body=Tuple(
        elts=[
            Constant (value=1),
            Constant (value=2),
            Constant (value=3)],
        ctx=Load()))

```

### *class ast.Set(*elts*)*

A set. *elts* holds a list of nodes representing the set's elements.

```

>>> print(ast.dump(ast.parse('{1, 2, 3}', mode='eval'),
Expression(
    body=Set(
        elts=[
            Constant (value=1),
            Constant (value=2),
            Constant (value=3)]))

```

### *class ast.Dict(*keys*, *values*)*

A dictionary. *keys* and *values* hold lists of nodes representing the keys and the values respectively, in matching order (what would be returned when calling `dictionary.keys()` and `dictionary.values()`).

When doing dictionary unpacking using dictionary literals the expression to be expanded goes in the *values* list, with a `None` at the corresponding position in *keys*.

```

>>> print(ast.dump(ast.parse('{"a":1, **d}', mode='eval'),
Expression(
    body=Dict(
        keys=[

```

```

        Constant (value='a'),
        None],
    values=[
        Constant (value=1),
        Name (id='d', ctx=Load()) ]))

```

## Variables

*class* ast.Name(*id*, *ctx*)

A variable name. *id* holds the name as a string, and *ctx* is one of the following types.

*class* ast.Load

*class* ast.Store

*class* ast.Del

Variable references can be used to load the value of a variable, to assign a new value to it, or to delete it. Variable references are given a context to distinguish these cases.

```

>>> print (ast.dump (ast.parse ('a'), indent=4))
Module (
  body=[
    Expr (
      value=Name (id='a', ctx=Load()) ),
    type_ignores=[])

>>> print (ast.dump (ast.parse ('a = 1'), indent=4))
Module (
  body=[
    Assign (
      targets=[
        Name (id='a', ctx=Store()) ],
      value=Constant (value=1) ),
    type_ignores=[])

>>> print (ast.dump (ast.parse ('del a'), indent=4))
Module (
  body=[

```

```

Delete(
    targets=[
        Name(id='a', ctx=Del())]],
    type_ignores=[])

```

*class* ast.Starred(*value*, *ctx*)

A *\*var* variable reference. *value* holds the variable, typically a **Name** node. This type must be used when building a **Call** node with *\*args*.

```

>>> print(ast.dump(ast.parse('a, *b = it'), indent=
Module(
    body=[
        Assign(
            targets=[
                Tuple(
                    elts=[
                        Name(id='a', ctx=Store()),
                        Starred(
                            value=Name(id='b', ctx=
                                ctx=Store())],
                            ctx=Store())],
                    value=Name(id='it', ctx=Load()))],
            type_ignores=[])

```

## Expressions

*class* ast.Expr(*value*)

When an expression, such as a function call, appears as a statement by itself with its return value not used or stored, it is wrapped in this container. *value* holds one of the other nodes in this section, a **Constant**, a **Name**, a **Lambda**, a **Yield** or **YieldFrom** node.

```

>>> print(ast.dump(ast.parse('-a'), indent=4))
Module(
    body=[
        Expr(

```

```

        value=UnaryOp(
            op=USub(),
            operand=Name(id='a', ctx=Load()))
    type_ignores=[])

```

*class ast.UnaryOp(op, operand)*

A unary operation. `op` is the operator, and `operand` any expression node.

*class ast.UAdd*

*class ast.USub*

*class ast.Not*

*class ast.Invert*

Unary operator tokens. **Not** is the `not` keyword, **Invert** is the `~` operator.

```

>>> print(ast.dump(ast.parse('not x', mode='eval'),
Expression(
    body=UnaryOp(
        op=Not(),
        operand=Name(id='x', ctx=Load()))))

```

*class ast.BinOp(left, op, right)*

A binary operation (like addition or division). `op` is the operator, and `left` and `right` are any expression nodes.

```

>>> print(ast.dump(ast.parse('x + y', mode='eval'),
Expression(
    body=BinOp(
        left=Name(id='x', ctx=Load()),
        op=Add(),
        right=Name(id='y', ctx=Load()))))

```

*class ast.Add*

*class ast.Sub*

*class ast.Mult*

*class ast.Div*

*class ast.FloorDiv*

```
class ast.Mod
class ast.Pow
class ast.LShift
class ast.RShift
class ast.BitOr
class ast.BitXor
class ast.BitAnd
class ast.MatMult
```

Binary operator tokens.

```
class ast.BoolOp(op, values)
```

A boolean operation, 'or' or 'and'. `op` is **Or** or **And**.  
`values` are the values involved. Consecutive operations with the same operator, such as `a or b or c`, are collapsed into one node with several values.

This doesn't include `not`, which is a **UnaryOp**.

```
>>> print(ast.dump(ast.parse('x or y', mode='eval')
Expression(
  body=BoolOp(
    op=Or(),
    values=[
      Name(id='x', ctx=Load()),
      Name(id='y', ctx=Load())]))
```

```
class ast.And
class ast.Or
```

Boolean operator tokens.

```
class ast.Compare(left, ops, comparators)
```

A comparison of two or more values. `left` is the first value in the comparison, `ops` the list of operators, and `comparators` the list of values after the first element in the comparison.

```
>>> print(ast.dump(ast.parse('1 <= a < 10', mode='e
Expression(
```

```

body=Compare(
    left=Constant(value=1),
    ops=[
        LtE(),
        Lt()],
    comparators=[
        Name(id='a', ctx=Load()),
        Constant(value=10)])

```

```

class ast.Eq
class ast.NotEq
class ast.Lt
class ast.LtE
class ast.Gt
class ast.GtE
class ast.Is
class ast.IsNot
class ast.In
class ast.NotIn

```

Comparison operator tokens.

*class ast.Call(func, args, keywords)*

A function call. `func` is the function, which will often be a **Name** or **Attribute** object. Of the arguments:

- `args` holds a list of the arguments passed by position.
- `keywords` holds a list of **keyword** objects representing arguments passed by keyword.

When creating a `Call` node, `args` and `keywords` are required, but they can be empty lists.

```

>>> print(ast.dump(ast.parse('func(a, b=c, *d, **e)
Expression(
    body=Call(
        func=Name(id='func', ctx=Load()),
        args=[
            Name(id='a', ctx=Load()),
            Starred(

```

```

        value=Name(id='d', ctx=Load()),
        ctx=Load())],
keywords=[
    keyword(
        arg='b',
        value=Name(id='c', ctx=Load())),
    keyword(
        value=Name(id='e', ctx=Load())))]))

```

*class ast.keyword(arg, value)*

A keyword argument to a function call or class definition. `arg` is a raw string of the parameter name, `value` is a node to pass in.

*class ast.IfExp(test, body, orelse)*

An expression such as `a if b else c`. Each field holds a single node, so in the following example, all three are **Name** nodes.

```

>>> print(ast.dump(ast.parse('a if b else c', mode='
Expression(
    body=IfExp(
        test=Name(id='b', ctx=Load()),
        body=Name(id='a', ctx=Load()),
        orelse=Name(id='c', ctx=Load()))))

```

*class ast.Attribute(value, attr, ctx)*

Attribute access, e.g. `d.keys`. `value` is a node, typically a **Name**. `attr` is a bare string giving the name of the attribute, and `ctx` is **Load**, **Store** or **Del** according to how the attribute is acted on.

```

>>> print(ast.dump(ast.parse('snake.colour', mode='
Expression(
    body=Attribute(
        value=Name(id='snake', ctx=Load()),
        attr='colour',
        ctx=Load()))

```

*class ast.NamedExpr(target, value)*

A named expression. This AST node is produced by the assignment expressions operator (also known as the walrus operator). As opposed to the **Assign** node in which the first argument can be multiple nodes, in this case both `target` and `value` must be single nodes.

```
>>> print(ast.dump(ast.parse('(x := 4)', mode='eval'),
Expression(
    body=NamedExpr(
        target=Name(id='x', ctx=Store()),
        value=Constant(value=4)))
```

*New in version 3.8.*

## Subscripting

*class ast.Subscript(value, slice, ctx)*

A subscript, such as `l[1]`. `value` is the subscripted object (usually sequence or mapping). `slice` is an index, slice or key. It can be a **Tuple** and contain a **Slice**. `ctx` is **Load**, **Store** or **Del** according to the action performed with the subscript.

```
>>> print(ast.dump(ast.parse('l[1:2, 3]', mode='eval'),
Expression(
    body=Subscript(
        value=Name(id='l', ctx=Load()),
        slice=Tuple(
            elts=[
                Slice(
                    lower=Constant(value=1),
                    upper=Constant(value=2)),
                Constant(value=3)],
            ctx=Load()),
        ctx=Load()))
```

*class ast.Slice(lower, upper, step)*

Regular slicing (on the form `lower:upper` or `lower:upper:step`). Can occur only inside the *slice* field of **Subscript**, either directly or as an element of **Tuple**.

```
>>> print(ast.dump(ast.parse('l[1:2]', mode='eval')
Expression(
  body=Subscript(
    value=Name(id='l', ctx=Load()),
    slice=Slice(
      lower=Constant(value=1),
      upper=Constant(value=2)),
    ctx=Load()))
```

## Comprehensions

```
class ast.ListComp(elt, generators)
class ast.SetComp(elt, generators)
class ast.GeneratorExp(elt, generators)
class ast.DictComp(key, value, generators)
```

List and set comprehensions, generator expressions, and dictionary comprehensions. `elt` (or `key` and `value`) is a single node representing the part that will be evaluated for each item.

`generators` is a list of **comprehension** nodes.

```
>>> print(ast.dump(ast.parse('[x for x in numbers]',
Expression(
  body=ListComp(
    elt=Name(id='x', ctx=Load()),
    generators=[
      comprehension(
        target=Name(id='x', ctx=Store()),
        iter=Name(id='numbers', ctx=Load()),
        ifs=[],
        is_async=0)))]))
>>> print(ast.dump(ast.parse('{x: x**2 for x in num
Expression(
```

```

body=DictComp(
    key=Name(id='x', ctx=Load()),
    value=BinOp(
        left=Name(id='x', ctx=Load()),
        op=Pow(),
        right=Constant(value=2)),
    generators=[
        comprehension(
            target=Name(id='x', ctx=Store()),
            iter=Name(id='numbers', ctx=Load()),
            ifs=[],
            is_async=0)))
>>> print(ast.dump(ast.parse('{x for x in numbers}'))
Expression(
    body=SetComp(
        elt=Name(id='x', ctx=Load()),
        generators=[
            comprehension(
                target=Name(id='x', ctx=Store()),
                iter=Name(id='numbers', ctx=Load()),
                ifs=[],
                is_async=0)))]))

```

*class ast.comprehension(target, iter, ifs, is\_async)*

One `for` clause in a comprehension. `target` is the reference to use for each element - typically a **Name** or **Tuple** node. `iter` is the object to iterate over. `ifs` is a list of test expressions: each `for` clause can have multiple `ifs`.

`is_async` indicates a comprehension is asynchronous (using an `async for` instead of `for`). The value is an integer (0 or 1).

```

>>> print(ast.dump(ast.parse('[ord(c) for line in f
...                             indent=4)') # Multiple comprehens
Expression(
    body=ListComp(
        elt=Call(
            func=Name(id='ord', ctx=Load()),

```

```

        args=[
            Name(id='c', ctx=Load())],
        keywords=[],
    generators=[
        comprehension(
            target=Name(id='line', ctx=Store()),
            iter=Name(id='file', ctx=Load()),
            ifs=[],
            is_async=0),
        comprehension(
            target=Name(id='c', ctx=Store()),
            iter=Name(id='line', ctx=Load()),
            ifs=[],
            is_async=0))])

>>> print(ast.dump(ast.parse('(n**2 for n in it if
...                          indent=4)) # generator comprehen
Expression(
    body=GeneratorExp(
        elt=BinOp(
            left=Name(id='n', ctx=Load()),
            op=Pow(),
            right=Constant(value=2)),
        generators=[
            comprehension(
                target=Name(id='n', ctx=Store()),
                iter=Name(id='it', ctx=Load()),
                ifs=[
                    Compare(
                        left=Name(id='n', ctx=Load(
                        ops=[
                            Gt()),
                        comparators=[
                            Constant(value=5))],
                    Compare(
                        left=Name(id='n', ctx=Load(
                        ops=[
                            Lt()),

```

```

comparators=[
    Constant (value=10) ] ],
is_async=0) ]))

>>> print(ast.dump(ast.parse('[i async for i in soc
...                          indent=4)) # Async comprehension
Expression(
  body=ListComp(
    elt=Name(id='i', ctx=Load()),
    generators=[
      comprehension(
        target=Name(id='i', ctx=Store()),
        iter=Name(id='soc', ctx=Load()),
        ifs=[],
        is_async=1) ]))

```

## Statements

*class* `ast.Assign(targets, value, type_comment)`

An assignment. `targets` is a list of nodes, and `value` is a single node.

Multiple nodes in `targets` represents assigning the same value to each. Unpacking is represented by putting a **Tuple** or **List** within `targets`.

`type_comment`

`type_comment` is an optional string with the type annotation as a comment.

```

>>> print(ast.dump(ast.parse('a = b = 1'), indent=4
Module(
  body=[
    Assign(
      targets=[
        Name(id='a', ctx=Store()),
        Name(id='b', ctx=Store()) ],
      value=Constant (value=1) ]),

```

```

type_ignores=[])

>>> print(ast.dump(ast.parse('a,b = c'), indent=4))
Module(
  body=[
    Assign(
      targets=[
        Tuple(
          elts=[
            Name(id='a', ctx=Store()),
            Name(id='b', ctx=Store())],
          ctx=Store())],
      value=Name(id='c', ctx=Load()))],
  type_ignores=[])

```

*class ast.Assign(target, annotation, value, simple)*

An assignment with a type annotation. `target` is a single node and can be a **Name**, a **Attribute** or a **Subscript**. `annotation` is the annotation, such as a **Constant** or **Name** node. `value` is a single optional node. `simple` is a boolean integer set to True for a **Name** node in `target` that do not appear in between parenthesis and are hence pure names and not expressions.

```

>>> print(ast.dump(ast.parse('c: int'), indent=4))
Module(
  body=[
    AnnAssign(
      target=Name(id='c', ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      simple=1)],
  type_ignores=[])

>>> print(ast.dump(ast.parse('(a): int = 1'), indent=4))
Module(
  body=[
    AnnAssign(
      target=Name(id='a', ctx=Store()),

```

```

        annotation=Name(id='int', ctx=Load()),
        value=Constant(value=1),
        simple=0)],
    type_ignores=[])

>>> print(ast.dump(ast.parse('a.b: int'), indent=4))
Module(
  body=[
    AnnAssign(
      target=Attribute(
        value=Name(id='a', ctx=Load()),
        attr='b',
        ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      simple=0)],
  type_ignores=[])

>>> print(ast.dump(ast.parse('a[1]: int'), indent=4))
Module(
  body=[
    AnnAssign(
      target=Subscript(
        value=Name(id='a', ctx=Load()),
        slice=Constant(value=1),
        ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      simple=0)],
  type_ignores=[])

```

*class* `ast.AugAssign(target, op, value)`

Augmented assignment, such as `a += 1`. In the following example, `target` is a **Name** node for `x` (with the **Store** context), `op` is **Add**, and `value` is a **Constant** with value for 1.

The `target` attribute cannot be of class **Tuple** or **List**, unlike the targets of **Assign**.

```
>>> print(ast.dump(ast.parse('x += 2'), indent=4))
```

```

Module (
    body=[
        AugAssign (
            target=Name (id='x', ctx=Store()),
            op=Add(),
            value=Constant (value=2)),
        type_ignores=[])

```

*class ast.Raise(exc, cause)*

A raise statement. exc is the exception object to be raised, normally a **Call** or **Name**, or None for a standalone raise. cause is the optional part for y in raise x from y.

```

>>> print(ast.dump(ast.parse('raise x from y'), indent=
Module (
    body=[
        Raise (
            exc=Name (id='x', ctx=Load()),
            cause=Name (id='y', ctx=Load()))],
        type_ignores=[])

```

*class ast.Assert(test, msg)*

An assertion. test holds the condition, such as a **Compare** node. msg holds the failure message.

```

>>> print(ast.dump(ast.parse('assert x,y'), indent=
Module (
    body=[
        Assert (
            test=Name (id='x', ctx=Load()),
            msg=Name (id='y', ctx=Load()))],
        type_ignores=[])

```

*class ast.Delete(targets)*

Represents a del statement. targets is a list of nodes, such as **Name**, **Attribute** or **Subscript** nodes.

```
>>> print(ast.dump(ast.parse('del x,y,z'), indent=4))
Module(
  body=[
    Delete(
      targets=[
        Name(id='x', ctx=Del()),
        Name(id='y', ctx=Del()),
        Name(id='z', ctx=Del())
      ]
    ),
  ],
  type_ignores=[])
```

### *class ast.Pass*

A pass statement.

```
>>> print(ast.dump(ast.parse('pass'), indent=4))
Module(
  body=[
    Pass()
  ],
  type_ignores=[])
```

### *class ast.TypeAlias(name, type\_params, value)*

A **type alias** created through the **type** statement. `name` is the name of the alias, `type_params` is a list of **type parameters**, and `value` is the value of the type alias.

```
>>> print(ast.dump(ast.parse('type Alias = int'), indent=4))
Module(
  body=[
    TypeAlias(
      name=Name(id='Alias', ctx=Store()),
      type_params=[],
      value=Name(id='int', ctx=Load())
    ),
  ],
  type_ignores=[])
```

*New in version 3.12.*

Other statements which are only applicable inside functions or loops are described in other sections.

## Imports

### *class ast.Import(names)*

An import statement. `names` is a list of **alias** nodes.

```
>>> print(ast.dump(ast.parse('import x,y,z'), indent=4))
Module(
  body=[
    Import(
      names=[
        alias(name='x'),
        alias(name='y'),
        alias(name='z')]
    ),
  ],
  type_ignores=[])
```

### *class ast.ImportFrom(module, names, level)*

Represents `from x import y`. `module` is a raw string of the ‘from’ name, without any leading dots, or `None` for statements such as `from . import foo`. `level` is an integer holding the level of the relative import (0 means absolute import).

```
>>> print(ast.dump(ast.parse('from y import x,y,z'), indent=4))
Module(
  body=[
    ImportFrom(
      module='y',
      names=[
        alias(name='x'),
        alias(name='y'),
        alias(name='z')]
      ,
      level=0
    ),
  ],
  type_ignores=[])
```

### *class ast.alias(name, asname)*

Both parameters are raw strings of the names. `asname` can be `None` if the regular name is to be used.

```
>>> print(ast.dump(ast.parse('from ..foo.bar import
Module(
    body=[
        ImportFrom(
            module='foo.bar',
            names=[
                alias(name='a', asname='b'),
                alias(name='c')],
            level=2)],
    type_ignores=[]))
```

## Control flow

### Note

Optional clauses such as `else` are stored as an empty list if they're not present.

*class ast.If(test, body, or\_else)*

An `if` statement. `test` holds a single node, such as a **Compare** node. `body` and `or_else` each hold a list of nodes.

`elif` clauses don't have a special representation in the AST, but rather appear as extra **If** nodes within the `or_else` section of the previous one.

```
>>> print(ast.dump(ast.parse("""
... if x:
...     ...
... elif y:
...     ...
... else:
...     ...
... """), indent=4))
Module(
    body=[
        If(
            test=Name(id='x', ctx=Load()),
```

```

        body=[
            Expr (
                value=Constant (value=Ellipsis))
        orelse=[
            If (
                test=Name (id='y', ctx=Load()),
                body=[
                    Expr (
                        value=Constant (value=El
                    orelse=[
                        Expr (
                            value=Constant (value=El
type_ignores=[]))

```

*class ast.For(target, iter, body, orelse, type\_comment)*

A for loop. *target* holds the variable(s) the loop assigns to, as a single **Name**, **Tuple**, **List**, **Attribute** or **Subscript** node. *iter* holds the item to be looped over, again as a single node. *body* and *orelse* contain lists of nodes to execute. Those in *orelse* are executed if the loop finishes normally, rather than via a `break` statement.

*type\_comment*

*type\_comment* is an optional string with the type annotation as a comment.

```

>>> print (ast.dump (ast.parse ("\"
... for x in y:
...     ...
... else:
...     ...
... \"\"\"), indent=4))
Module(
    body=[
        For(
            target=Name(id='x', ctx=Store()),
            iter=Name(id='y', ctx=Load()),
            body=[

```

```

        Expr (
            value=Constant (value=Ellipsis))
    orelse=[
        Expr (
            value=Constant (value=Ellipsis))
    type_ignores=[])
```

*class ast.While(test, body, orelse)*

A while loop. test holds the condition, such as a **Compare** node.

```
>> print(ast.dump(ast.parse("""
... while x:
...     ...
... else:
...     ...
... """), indent=4))
Module(
  body=[
    While(
      test=Name(id='x', ctx=Load()),
      body=[
        Expr(
          value=Constant(value=Ellipsis))
      orelse=[
        Expr(
          value=Constant(value=Ellipsis))
      type_ignores=[])])]
```

*class ast.Break*

*class ast.Continue*

The break and continue statements.

```
>>> print(ast.dump(ast.parse("""\
... for a in b:
...     if a > 5:
...         break
...     else:
```

```

...         continue
...
... """), indent=4))
Module(
    body=[
        For(
            target=Name(id='a', ctx=Store()),
            iter=Name(id='b', ctx=Load()),
            body=[
                If(
                    test=Compare(
                        left=Name(id='a', ctx=Load(
                            ops=[
                                Gt()],
                                comparators=[
                                    Constant(value=5)])),
                    body=[
                        Break()],
                    orelse=[
                        Continue()])],
                orelse=[])],
            type_ignores=[]))

```

*class ast.Try(body, handlers, orelse, finalbody)*

try blocks. All attributes are list of nodes to execute, except for handlers, which is a list of **ExceptionHandler** nodes.

```

>>> print(ast.dump(ast.parse("""
... try:
...     ...
... except Exception:
...     ...
... except OtherException as e:
...     ...
... else:
...     ...
... finally:
...     ...

```

```

... """), indent=4))
Module(
    body=[
        Try(
            body=[
                Expr(
                    value=Constant(value=Ellipsis))
            handlers=[
                ExceptHandler(
                    type=Name(id='Exception', ctx=L
                    body=[
                        Expr(
                            value=Constant(value=El
                ExceptHandler(
                    type=Name(id='OtherException',
                    name='e',
                    body=[
                        Expr(
                            value=Constant(value=El
            orelse=[
                Expr(
                    value=Constant(value=Ellipsis))
            finalbody=[
                Expr(
                    value=Constant(value=Ellipsis))
            type_ignores=[]))

```

*class ast.TryStar(body, handlers, orelse, finalbody)*

try blocks which are followed by `except*` clauses. The attributes are the same as for **Try** but the **ExceptHandler** nodes in `handlers` are interpreted as `except*` blocks rather than `except`.

```

>>> print(ast.dump(ast.parse("""
... try:
...     ...
... except* Exception:
...     ...

```

```

... """), indent=4))
Module(
    body=[
        TryStar(
            body=[
                Expr(
                    value=Constant(value=Ellipsis))
            ],
            handlers=[
                ExceptHandler(
                    type=Name(id='Exception', ctx=L
                    body=[
                        Expr(
                            value=Constant(value=El
                        ),
                    ],
                    finalbody=[])],
            type_ignores=[])

```

*New in version 3.11.*

*class* ast.ExceptHandler(*type*, *name*, *body*)

A single except clause. *type* is the exception type it will match, typically a **Name** node (or `None` for a catch-all except: clause). *name* is a raw string for the name to hold the exception, or `None` if the clause doesn't have `as foo`. *body* is a list of nodes.

```

>>> print(ast.dump(ast.parse("""\
... try:
...     a + 1
... except TypeError:
...     pass
... """), indent=4))
Module(
    body=[
        Try(
            body=[
                Expr(
                    value=BinOp(
                        left=Name(id='a', ctx=Load(

```

```

        op=Add(),
        right=Constant(value=1))]],
    handlers=[
        ExceptHandler(
            type=Name(id='TypeError', ctx=L),
            body=[
                Pass()])],
    orelse=[],
    finalbody=[])],
    type_ignores=[])

```

*class* ast.With(*items*, *body*, *type\_comment*)

A `with` block. *items* is a list of `withitem` nodes representing the context managers, and *body* is the indented block inside the context.

*type\_comment*

*type\_comment* is an optional string with the type annotation as a comment.

*class* ast.withitem(*context\_expr*, *optional\_vars*)

A single context manager in a `with` block. *context\_expr* is the context manager, often a `Call` node. *optional\_vars* is a `Name`, `Tuple` or `List` for the `as` *foo* part, or `None` if that isn't used.

```

>>> print(ast.dump(ast.parse("""\
... with a as b, c as d:
...     something(b, d)
... """), indent=4))
Module(
  body=[
    With(
      items=[
        withitem(
          context_expr=Name(id='a', ctx=L),
          optional_vars=Name(id='b', ctx=L),
          withitem(

```

```

        context_expr=Name(id='c', ctx=L
        optional_vars=Name(id='d', ctx=
body=[
    Expr(
        value=Call(
            func=Name(id='something', c
            args=[
                Name(id='b', ctx=Load()
                Name(id='d', ctx=Load()
            keywords=[])))]),
    type_ignores=[]])

```

## Pattern matching

*class ast.Match(subject, cases)*

A `match` statement. `subject` holds the subject of the match (the object that is being matched against the cases) and `cases` contains an iterable of `match_case` nodes with the different cases.

*New in version 3.10.*

*class ast.match\_case(pattern, guard, body)*

A single case pattern in a `match` statement. `pattern` contains the match pattern that the subject will be matched against. Note that the **AST** nodes produced for patterns differ from those produced for expressions, even when they share the same syntax.

The `guard` attribute contains an expression that will be evaluated if the pattern matches the subject.

`body` contains a list of nodes to execute if the pattern matches and the result of evaluating the guard expression is `true`.

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] if x>0:

```

```

...         ...
...     case tuple():
...         ...
...     """), indent=4))
Module(
    body=[
        Match(

```

*New in version 3.10.*

*class ast.MatchValue(value)*

A match literal or value pattern that compares by equality.  
 value is an expression node. Permitted value nodes are

restricted as described in the match statement documentation. This pattern succeeds if the match subject is equal to the evaluated value.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case "Relevant":
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchValue(
            value=Constant(value='Relev
          body=[
            Expr(
              value=Constant(value=El
      type_ignores=[])
```

*New in version 3.10.*

*class* ast.MatchSingleton(*value*)

A match literal pattern that compares by identity. *value* is the singleton to be compared against: `None`, `True`, or `False`. This pattern succeeds if the match subject is the given constant.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case None:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
```

```

        cases=[
            match_case(
                pattern=MatchSingleton(value=No
                body=[
                    Expr(
                        value=Constant(value=El
type_ignores=[]))

```

*New in version 3.10.*

*class* ast.MatchSequence(*patterns*)

A match sequence pattern. *patterns* contains the patterns to be matched against the subject elements if the subject is a sequence. Matches a variable length sequence if one of the subpatterns is a `MatchStar` node, otherwise matches a fixed length sequence.

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case [1, 2]:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchSequence(
            patterns=[
              MatchValue(
                value=Constant(valu
              MatchValue(
                value=Constant(valu
            body=[
              Expr(
                value=Constant(value=El
      type_ignores=[]))

```

*New in version 3.10.*

*class* ast.MatchStar(*name*)

Matches the rest of the sequence in a variable length match sequence pattern. If *name* is not *None*, a list containing the remaining sequence elements is bound to that name if the overall sequence pattern is successful.

```
>>> print(ast.dump(ast.parse("""
```

```
... match x:
```

```
...     case [1, 2, *rest]:
```

```
...         ...
```

```
...     case [*_]:
```

```
...         ...
```

```
... """), indent=4))
```

```
Module(
```

```
    body=[
```

```
        Match(

```

```
type_ignores=[])
```

*New in version 3.10.*

*class* ast.MatchMapping(*keys, patterns, rest*)

A match mapping pattern. *keys* is a sequence of expression nodes. *patterns* is a corresponding sequence of pattern nodes. *rest* is an optional name that can be specified to capture the remaining mapping elements. Permitted key expressions are restricted as described in the match statement documentation.

This pattern succeeds if the subject is a mapping, all evaluated key expressions are present in the mapping, and the value corresponding to each key matches the corresponding subpattern. If *rest* is not *None*, a dict containing the remaining mapping elements is bound to that name if the overall mapping pattern is successful.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case {1: _, 2: _}:
...         ...
...     case {**rest}:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchMapping(
            keys=[
              Constant(value=1),
              Constant(value=2)],
            patterns=[
              MatchAs(),
              MatchAs()])],
```

```

        body=[
            Expr (
                value=Constant (value=El
match_case (
    pattern=MatchMapping (keys=[], p
    body=[
        Expr (
            value=Constant (value=El
type_ignores=[])

```

*New in version 3.10.*

*class* ast.MatchClass(*cls, patterns, kwd\_attrs, kwd\_patterns*)

A match class pattern. *cls* is an expression giving the nominal class to be matched. *patterns* is a sequence of pattern nodes to be matched against the class defined sequence of pattern matching attributes. *kwd\_attrs* is a sequence of additional attributes to be matched (specified as keyword arguments in the class pattern), *kwd\_patterns* are the corresponding patterns (specified as keyword values in the class pattern).

This pattern succeeds if the subject is an instance of the nominated class, all positional patterns match the corresponding class-defined attributes, and any specified keyword attributes match their corresponding pattern.

Note: classes may define a property that returns self in order to match a pattern node against the instance being matched. Several builtin types are also matched that way, as described in the match statement documentation.

```

>>> print (ast.dump (ast.parse (" "
... match x:
...     case Point2D(0, 0):
...         ...
...     case Point3D(x=0, y=0, z=0):
...         ...
... """), indent=4))

```

```

Module (
  body=[
    Match (
      subject=Name (id='x', ctx=Load()),
      cases=[
        match_case (
          pattern=MatchClass (
            cls=Name (id='Point2D', ctx=Load()),

                          type_ignores=[]))

```

*New in version 3.10.*

*class ast.MatchAs(pattern, name)*

A match “as-pattern”, capture pattern or wildcard pattern. `pattern` contains the match pattern that the subject will be matched against. If the pattern is `None`, the node represents a capture pattern (i.e a bare name) and will always succeed.

The `name` attribute contains the name that will be bound if the pattern is successful. If `name` is `None`, `pattern` must also be `None` and the node represents the wildcard pattern.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] as y:
...         ...
...     case _:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchAs(
            pattern=MatchSequence(
              patterns=[
                MatchAs(name='x')])
            name='y'),
          body=[
            Expr(
              value=Constant(value=El
match_case(
  pattern=MatchAs(),
  body=[
    Expr(
      value=Constant(value=El
type_ignores=[])
```

*New in version 3.10.*

*class ast.MatchOr(patterns)*

A match “or-pattern”. An or-pattern matches each of its subpatterns in turn to the subject, until one succeeds. The or-pattern is then deemed to succeed. If none of the subpatterns succeed the or-pattern fails. The `patterns` attribute contains a list of match pattern nodes that will be matched against the subject.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] | (y):
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchOr(
            patterns=[
              MatchSequence(
                patterns=[
                  MatchAs(name='x'),
                  MatchAs(name='y')]
                ),
              body=[
                Expr(
                  value=Constant(value=El
type_ignores=[])
```

*New in version 3.10.*

## Type parameters

[Type parameters](#) can exist on classes, functions, and type aliases.

*class ast.TypeVar(name, bound)*

A [typing.TypeVar](#). `name` is the name of the type variable.

bound is the bound or constraints, if any. If bound is a **Tuple**, it represents constraints; otherwise it represents the bound.

```
>>> print(ast.dump(ast.parse("type Alias[T: int] =  
Module(  
    body=[  
        TypeAlias(  
            name=Name(id='Alias', ctx=Store()),  
            type_params=[  
                TypeVar(  
                    name='T',  
                    bound=Name(id='int', ctx=Load()),  
                    value=Subscript(  
                        value=Name(id='list', ctx=Load()),  
                        slice=Name(id='T', ctx=Load()),  
                        ctx=Load())]),  
            type_ignores=[]))
```

*New in version 3.12.*

*class ast.ParamSpec(name)*

A **typing.ParamSpec**. name is the name of the parameter specification.

```
>>> print(ast.dump(ast.parse("type Alias[**P] = Cal  
Module(  
    body=[  
        TypeAlias(  
            name=Name(id='Alias', ctx=Store()),  
            type_params=[  
                ParamSpec(name='P')],  
            value=Subscript(  
                value=Name(id='Callable', ctx=Load()),  
                slice=Tuple(  
                    elts=[  
                        Name(id='P', ctx=Load()),  
                        Name(id='int', ctx=Load())]  
                ctx=Load()),
```

```

        ctx=Load()))],
    type_ignores=[])

```

*New in version 3.12.*

*class* `ast.TypeVarTuple(name)`

A `typing.TypeVarTuple`. `name` is the name of the type variable tuple.

```

>>> print(ast.dump(ast.parse("type Alias[*Ts] = tuple",
Module(
    body=[
        TypeAlias(
            name=Name(id='Alias', ctx=Store()),
            type_params=[
                TypeVarTuple(name='Ts')],
            value=Subscript(
                value=Name(id='tuple', ctx=Load()),
                slice=Tuple(
                    elts=[
                        Starred(
                            value=Name(id='Ts', ctx=Load()),
                            ctx=Load())],
                        ctx=Load()),
                    ctx=Load()))],
            type_ignores=[])

```

*New in version 3.12.*

## Function and class definitions

*class* `ast.FunctionDef(name, args, body, decorator_list, returns, type_comment, type_params)`

A function definition.

- `name` is a raw string of the function name.
- `args` is an `arguments` node.
- `body` is the list of nodes inside the function.

- `decorator_list` is the list of decorators to be applied, stored outermost first (i.e. the first in the list will be applied last).
- `returns` is the return annotation.
- `type_params` is a list of [type parameters](#).

`type_comment`

`type_comment` is an optional string with the type annotation as a comment.

*Changed in version 3.12:* Added `type_params`.

*class* `ast.Lambda(args, body)`

`lambda` is a minimal function definition that can be used inside an expression. Unlike [FunctionDef](#), `body` holds a single node.

```
>>> print(ast.dump(ast.parse('lambda x,y: ...'), in
Module(
  body=[
    Expr(
      value=Lambda(
        args=arguments(
          posonlyargs=[],
          args=[
            arg(arg='x'),
            arg(arg='y')],
          kwonlyargs=[],
          kw_defaults=[],
          defaults=[]),
        body=Constant(value=Ellipsis))),
    type_ignores=[])
```

*class* `ast.arguments(posonlyargs, args, vararg, kwonlyargs, kw_defaults, kwarg, defaults)`

The arguments for a function.

- `posonlyargs`, `args` and `kwonlyargs` are lists of

**arg** nodes.

- `vararg` and `kwarg` are single **arg** nodes, referring to the `*args`, `**kwargs` parameters.
- `kw_defaults` is a list of default values for keyword-only arguments. If one is `None`, the corresponding argument is required.
- `defaults` is a list of default values for arguments that can be passed positionally. If there are fewer defaults, they correspond to the last `n` arguments.

*class* `ast.arg(arg, annotation, type_comment)`

A single argument in a list. `arg` is a raw string of the argument name, `annotation` is its annotation, such as a **Str** or **Name** node.

`type_comment`

`type_comment` is an optional string with the type annotation as a comment

```
>>> print(ast.dump(ast.parse("""\n... @decorator1\n... @decorator2\n... def f(a: 'annotation', b=1, c=2, *d, e, f=3, **\n...     pass\n... """), indent=4))\nModule(\n  body=[\n    FunctionDef(\n      name='f',\n      args=arguments(\n        posonlyargs=[],\n        args=[\n          arg(\n            arg='a',\n            annotation=Constant(value=''\n            arg(arg='b'),\n            arg(arg='c')],\n            vararg=arg(arg='d'),
```

```

        kwonlyargs=[
            arg(arg='e'),
            arg(arg='f')],
        kw_defaults=[
            None,
            Constant(value=3)],
        kwarg=arg(arg='g'),
        defaults=[
            Constant(value=1),
            Constant(value=2)],
    body=[
        Pass()],
    decorator_list=[
        Name(id='decorator1', ctx=Load()),
        Name(id='decorator2', ctx=Load())],
    returns=Constant(value='return annotation'),
    type_params=[],
    type_ignores=[])

```

*class* `ast.Return(value)`

A return statement.

```

>>> print(ast.dump(ast.parse('return 4'), indent=4))
Module(
    body=[
        Return(
            value=Constant(value=4))],
    type_ignores=[])

```

*class* `ast.Yield(value)`

*class* `ast.YieldFrom(value)`

A yield or yield from expression. Because these are expressions, they must be wrapped in a `Expr` node if the value sent back is not used.

```

>>> print(ast.dump(ast.parse('yield x'), indent=4))
Module(
    body=[

```

```

        Expr(
            value=Yield(
                value=Name(id='x', ctx=Load()))),
        type_ignores=[])

>>> print(ast.dump(ast.parse('yield from x'), indent=4))
Module(
    body=[
        Expr(
            value=YieldFrom(
                value=Name(id='x', ctx=Load()))),
        type_ignores=[])

```

*class ast.Global(names)*

*class ast.Nonlocal(names)*

global and nonlocal statements. names is a list of raw strings.

```

>>> print(ast.dump(ast.parse('global x,y,z'), indent=4))
Module(
    body=[
        Global(
            names=[
                'x',
                'y',
                'z'])],
        type_ignores=[])

>>> print(ast.dump(ast.parse('nonlocal x,y,z'), indent=4))
Module(
    body=[
        Nonlocal(
            names=[
                'x',
                'y',
                'z'])],
        type_ignores=[])

```

*class* ast.ClassDef(*name*, *bases*, *keywords*, *body*, *decorator\_list*,  
*type\_params*)

A class definition.

- *name* is a raw string for the class name
- *bases* is a list of nodes for explicitly specified base classes.
- *keywords* is a list of **keyword** nodes, principally for ‘metaclass’. Other keywords will be passed to the metaclass, as per **PEP-3115** [<https://peps.python.org/pep-3115/>].
- *body* is a list of nodes representing the code within the class definition.
- *decorator\_list* is a list of nodes, as in **FunctionDef**.
- *type\_params* is a list of **type parameters**.

```
>>> print(ast.dump(ast.parse("""\n... @decorator1\n... @decorator2\n... class Foo(base1, base2, metaclass=meta):\n...     pass\n... """), indent=4))\nModule(\n  body=[\n    ClassDef(\n      name='Foo',\n      bases=[\n        Name(id='base1', ctx=Load()),\n        Name(id='base2', ctx=Load())],\n      keywords=[\n        keyword(\n          arg='metaclass',\n          value=Name(id='meta', ctx=Load()),\n        ),\n      ],\n      body=[\n        Pass(),\n      ],\n      decorator_list=[\n        Name(id='decorator1', ctx=Load()),\n        Name(id='decorator2', ctx=Load())],\n    ),\n  ],\n)
```

```
        type_params=[])],
    type_ignores=[])
```

*Changed in version 3.12:* Added `type_params`.

## Async and await

*class* `ast.AsyncFunctionDef(name, args, body, decorator_list, returns, type_comment, type_params)`

An `async def` function definition. Has the same fields as [FunctionDef](#).

*Changed in version 3.12:* Added `type_params`.

*class* `ast.Await(value)`

An `await` expression. `value` is what it waits for. Only valid in the body of an [AsyncFunctionDef](#).

```
>>> print(ast.dump(ast.parse("""\
... async def f():
...     await other_func()
... """), indent=4))
Module(
  body=[
    AsyncFunctionDef(
      name='f',
      args=arguments(
        posonlyargs=[],
        args=[],
        kwonlyargs=[],
        kw_defaults=[],
        defaults=[]),
      body=[
        Expr(
          value=Await(
            value=Call(
              func=Name(id='other_func', c
              args=[],
```

```

keywords=[])])],
decorator_list=[],
type_params=[])],
type_ignores=[])

```

*class ast.AsyncFor(target, iter, body, orelse, type\_comment)*

*class ast.AsyncWith(items, body, type\_comment)*

`async for` loops and `async with` context managers. They have the same fields as **For** and **With**, respectively. Only valid in the body of an **AsyncFunctionDef**.

## Note

When a string is parsed by **ast.parse()**, operator nodes (subclasses of **ast.operator**, **ast.unaryop**, **ast.cmpop**, **ast.boolop** and **ast.expr\_context**) on the returned tree will be singletons. Changes to one will be reflected in all other occurrences of the same value (e.g. **ast.Add**).

## ast Helpers

Apart from the node classes, the **ast** module defines these utility functions and classes for traversing abstract syntax trees:

**ast.parse(source, filename='<unknown>', mode='exec', \*, type\_comments=False, feature\_version=None)**

Parse the source into an AST node. Equivalent to `compile(source, filename, mode, ast.PyCF_ONLY_AST)`.

If `type_comments=True` is given, the parser is modified to check and return type comments as specified by **PEP 484** [<https://peps.python.org/pep-0484/>] and **PEP 526** [<https://peps.python.org/pep-0526/>]. This is equivalent to adding **ast.PyCF\_TYPE\_COMMENTS** to the flags passed to **compile()**. This will report syntax errors for misplaced type comments. Without this flag, type comments will be ignored,

and the `type_comment` field on selected AST nodes will always be `None`. In addition, the locations of `# type: ignore` comments will be returned as the `type_ignores` attribute of `Module` (otherwise it is always an empty list).

In addition, if `mode` is `'func_type'`, the input syntax is modified to correspond to [PEP 484](https://peps.python.org/pep-0484/) [https://peps.python.org/pep-0484/] “signature type comments”, e.g. `(str, int) -> List[str]`.

Also, setting `feature_version` to a tuple `(major, minor)` will attempt to parse using that Python version’s grammar. Currently `major` must equal to 3. For example, setting `feature_version=(3, 4)` will allow the use of `async` and `await` as variable names. The lowest supported version is `(3, 4)`; the highest is `sys.version_info[0:2]`.

If source contains a null character (`'\0'`), `ValueError` is raised.

### Warning

Note that successfully parsing source code into an AST object doesn’t guarantee that the source code provided is valid Python code that can be executed as the compilation step can raise further `SyntaxError` exceptions. For instance, the source `return 42` generates a valid AST node for a return statement, but it cannot be compiled alone (it needs to be inside a function node).

In particular, `ast.parse()` won’t do any scoping checks, which the compilation step does.

### Warning

It is possible to crash the Python interpreter with a sufficiently large/complex string due to stack depth limitations in Python’s AST compiler.

*Changed in version 3.8:* Added `type_comments`, `mode='func_type'` and `feature_version`.

`ast.unparse(ast_obj)`

Unparse an `ast.AST` object and generate a string with code that would produce an equivalent `ast.AST` object if parsed back with `ast.parse()`.

### Warning

The produced code string will not necessarily be equal to the original code that generated the `ast.AST` object (without any compiler optimizations, such as constant tuples/frozensets).

### Warning

Trying to unparse a highly complex expression would result with `RecursionError`.

*New in version 3.9.*

`ast.literal_eval(node_or_string)`

Evaluate an expression node or a string containing only a Python literal or container display. The string or node provided may only consist of the following Python literal structures: strings, bytes, numbers, tuples, lists, dicts, sets, booleans, `None` and `Ellipsis`.

This can be used for evaluating strings containing Python values without the need to parse the values oneself. It is not capable of evaluating arbitrarily complex expressions, for example involving operators or indexing.

This function had been documented as “safe” in the past without defining what that meant. That was misleading. This is specifically designed not to execute Python code, unlike the more general `eval()`. There is no namespace, no name lookups, or ability to call out. But it is not free from attack: A

relatively small input can lead to memory exhaustion or to C stack exhaustion, crashing the process. There is also the possibility for excessive CPU consumption denial of service on some inputs. Calling it on untrusted data is thus not recommended.

### Warning

It is possible to crash the Python interpreter due to stack depth limitations in Python's AST compiler.

It can raise `ValueError`, `TypeError`, `SyntaxError`, `MemoryError` and `RecursionError` depending on the malformed input.

*Changed in version 3.2:* Now allows bytes and set literals.

*Changed in version 3.9:* Now supports creating empty sets with `'set()'`.

*Changed in version 3.10:* For string inputs, leading spaces and tabs are now stripped.

`ast.get_docstring(node, clean=True)`

Return the docstring of the given *node* (which must be a `FunctionDef`, `AsyncFunctionDef`, `ClassDef`, or `Module` node), or `None` if it has no docstring. If *clean* is true, clean up the docstring's indentation with `inspect.cleandoc()`.

*Changed in version 3.5:* `AsyncFunctionDef` is now supported.

`ast.get_source_segment(source, node, *, padded=False)`

Get source code segment of the *source* that generated *node*. If some location information (`lineno`, `end_lineno`, `col_offset`, or `end_col_offset`) is missing, return `None`.

If *padded* is `True`, the first line of a multi-line statement will

be padded with spaces to match its original position.

*New in version 3.8.*

`ast.fix_missing_locations(node)`

When you compile a node tree with `compile()`, the compiler expects `lineno` and `col_offset` attributes for every node that supports them. This is rather tedious to fill in for generated nodes, so this helper adds these attributes recursively where not already set, by setting them to the values of the parent node. It works recursively starting at *node*.

`ast.increment_lineno(node, n=1)`

Increment the line number and end line number of each node in the tree starting at *node* by *n*. This is useful to “move code” to a different location in a file.

`ast.copy_location(new_node, old_node)`

Copy source location (`lineno`, `col_offset`, `end_lineno`, and `end_col_offset`) from *old\_node* to *new\_node* if possible, and return *new\_node*.

`ast.iter_fields(node)`

Yield a tuple of (`fieldname`, `value`) for each field in `node._fields` that is present on *node*.

`ast.iter_child_nodes(node)`

Yield all direct child nodes of *node*, that is, all fields that are nodes and all items of fields that are lists of nodes.

`ast.walk(node)`

Recursively yield all descendant nodes in the tree starting at *node* (including *node* itself), in no specified order. This is useful if you only want to modify nodes in place and don’t care about the context.

*class* ast.NodeVisitor

A node visitor base class that walks the abstract syntax tree and calls a visitor function for every node found. This function may return a value which is forwarded by the `visit()` method.

This class is meant to be subclassed, with the subclass adding visitor methods.

`visit(node)`

Visit a node. The default implementation calls the method called `self.visit_classname` where *classname* is the name of the node class, or `generic_visit()` if that method doesn't exist.

`generic_visit(node)`

This visitor calls `visit()` on all children of the node.

Note that child nodes of nodes that have a custom visitor method won't be visited unless the visitor calls `generic_visit()` or visits them itself.

Don't use the `NodeVisitor` if you want to apply changes to nodes during traversal. For this a special visitor exists (`NodeTransformer`) that allows modifications.

*Deprecated since version 3.8:* Methods `visit_Num()`, `visit_Str()`, `visit_Bytes()`, `visit_NameConstant()` and `visit_Ellipsis()` are deprecated now and will not be called in future Python versions. Add the `visit_Constant()` method to handle all constant nodes.

*class* ast.NodeTransformer

A `NodeVisitor` subclass that walks the abstract syntax tree and allows modification of nodes.

The `NodeTransformer` will walk the AST and use the return value of the visitor methods to replace or remove the

old node. If the return value of the visitor method is `None`, the node will be removed from its location, otherwise it is replaced with the return value. The return value may be the original node in which case no replacement takes place.

Here is an example transformer that rewrites all occurrences of name lookups (`foo`) to `data['foo']`:

```
class RewriteName(NodeTransformer):

    def visit_Name(self, node):
        return Subscript(
            value=Name(id='data', ctx=Load()),
            slice=Constant(value=node.id),
            ctx=node.ctx
        )
```

Keep in mind that if the node you're operating on has child nodes you must either transform the child nodes yourself or call the **`generic_visit()`** method for the node first.

For nodes that were part of a collection of statements (that applies to all statement nodes), the visitor may also return a list of nodes rather than just a single node.

If **`NodeTransformer`** introduces new nodes (that weren't part of original tree) without giving them location information (such as **`lineno`**), **`fix_missing_locations()`** should be called with the new sub-tree to recalculate the location information:

```
tree = ast.parse('foo', mode='eval')
new_tree = fix_missing_locations(RewriteName().visit(tree))
```

Usually you use the transformer like this:

```
node = YourTransformer().visit(node)
```

```
ast.dump(node, annotate_fields=True, include_attributes=False, *,
indent=None)
```

Return a formatted dump of the tree in *node*. This is mainly useful for debugging purposes. If *annotate\_fields* is true (by default), the returned string will show the names and the values for fields. If *annotate\_fields* is false, the result string will be more compact by omitting unambiguous field names. Attributes such as line numbers and column offsets are not dumped by default. If this is wanted, *include\_attributes* can be set to true.

If *indent* is a non-negative integer or string, then the tree will be pretty-printed with that indent level. An indent level of 0, negative, or "" will only insert newlines. None (the default) selects the single line representation. Using a positive integer indents that many spaces per level. If *indent* is a string (such as "\t"), that string is used to indent each level.

*Changed in version 3.9:* Added the *indent* option.

## Compiler Flags

The following flags may be passed to `compile()` in order to change effects on the compilation of a program:

`ast.PyCF_ALLOW_TOP_LEVEL_AWAIT`

Enables support for top-level `await`, `async for`, `async with` and `async comprehensions`.

*New in version 3.8.*

`ast.PyCF_ONLY_AST`

Generates and returns an abstract syntax tree instead of returning a compiled code object.

`ast.PyCF_TYPE_COMMENTS`

Enables support for [PEP 484](https://peps.python.org/pep-0484/) and [PEP 526](https://peps.python.org/pep-0526/) style type comments (`# type: <type>`, `# type: ignore`, `<stuff>`).

*New in version 3.8.*

## Command-Line Usage

*New in version 3.9.*

The **ast** module can be executed as a script from the command line. It is as simple as:

```
python -m ast [-m <mode>] [-a] [infile]
```

The following options are accepted:

**-h, --help**

Show the help message and exit.

**-m <mode>**

**--mode <mode>**

Specify what kind of code must be compiled, like the *mode* argument in **parse()**.

**--no-type-comments**

Don't parse type comments.

**-a, --include-attributes**

Include attributes such as line numbers and column offsets.

**-i <indent>**

**--indent <indent>**

Indentation of nodes in AST (number of spaces).

If *infile* is specified its contents are parsed to AST and dumped to stdout. Otherwise, the content is read from stdin.

Python ASTs.

**ASTTokens** [<https://asttokens.readthedocs.io/en/latest/user-guide.html>] annotates Python ASTs with the positions of tokens and text in the source code that generated them. This is helpful for tools that make source code transformations.

**leoAst.py** [<https://leoeditor.com/appendices.html#leoast-py>] unifies the token-based and parse-tree-based views of python programs by inserting two-way links between tokens and ast nodes.

**LibCST** [<https://libcst.readthedocs.io/>] parses code as a Concrete Syntax Tree that looks like an ast tree and keeps all formatting details. It's useful for building automated refactoring (codemod) applications and linters.

**Parso** [<https://parso.readthedocs.io>] is a Python parser that supports error recovery and round-trip parsing for different Python versions (in multiple Python versions). Parso is also able to list multiple syntax errors in your python file.

# `symtable` — Access to the compiler's symbol tables

**Source code:** [Lib/symtable.py](https://github.com/python/cpython/tree/3.12/Lib/symtable.py) [https://github.com/python/cpython/tree/3.12/Lib/symtable.py]

---

Symbol tables are generated by the compiler from AST just before bytecode is generated. The symbol table is responsible for calculating the scope of every identifier in the code. `symtable` provides an interface to examine these tables.

## Generating Symbol Tables

`symtable.symtable(code, filename, compile_type)`

Return the toplevel `SymbolTable` for the Python source *code*. *filename* is the name of the file containing the code. *compile\_type* is like the *mode* argument to `compile()`.

## Examining Symbol Tables

`class symtable.SymbolTable`

A namespace table for a block. The constructor is not public.

`get_type()`

Return the type of the symbol table. Possible values are 'class', 'module', 'function', 'annotation', 'TypeVar bound', 'type alias', and 'type parameter'. The latter four refer to different flavors of [annotation scopes](#).

*Changed in version 3.12:* Added 'annotation', 'TypeVar bound', 'type alias', and 'type

parameter' as possible return values.

`get_id()`

Return the table's identifier.

`get_name()`

Return the table's name. This is the name of the class if the table is for a class, the name of the function if the table is for a function, or 'top' if the table is global (`get_type()` returns 'module'). For type parameter scopes (which are used for generic classes, functions, and type aliases), it is the name of the underlying class, function, or type alias. For type alias scopes, it is the name of the type alias. For `TypeVar` bound scopes, it is the name of the `TypeVar`.

`get_lineno()`

Return the number of the first line in the block this table represents.

`is_optimized()`

Return `True` if the locals in this table can be optimized.

`is_nested()`

Return `True` if the block is a nested class or function.

`has_children()`

Return `True` if the block has nested namespaces within it. These can be obtained with `get_children()`.

`get_identifiers()`

Return a view object containing the names of symbols in the table. See the [documentation of view objects](#).

`lookup(name)`

Lookup *name* in the table and return a **Symbol** instance.

`get_symbols()`

Return a list of **Symbol** instances for names in the table.

`get_children()`

Return a list of the nested symbol tables.

*class* `symtable.Function`

A namespace for a function or method. This class inherits **SymbolTable**.

`get_parameters()`

Return a tuple containing names of parameters to this function.

`get_locals()`

Return a tuple containing names of locals in this function.

`get_globals()`

Return a tuple containing names of globals in this function.

`get_nonlocals()`

Return a tuple containing names of nonlocals in this function.

`get_frees()`

Return a tuple containing names of free variables in this function.

*class* symtable.Class

A namespace of a class. This class inherits [SymbolTable](#).

get\_methods()

Return a tuple containing the names of methods declared in the class.

*class* symtable.Symbol

An entry in a [SymbolTable](#) corresponding to an identifier in the source. The constructor is not public.

get\_name()

Return the symbol's name.

is\_referenced()

Return `True` if the symbol is used in its block.

is\_imported()

Return `True` if the symbol is created from an import statement.

is\_parameter()

Return `True` if the symbol is a parameter.

is\_global()

Return `True` if the symbol is global.

is\_nonlocal()

Return `True` if the symbol is nonlocal.

is\_declared\_global()

Return `True` if the symbol is declared global with a global statement.

is\_local()

Return `True` if the symbol is local to its block.

`is_annotated()`

Return `True` if the symbol is annotated.

*New in version 3.6.*

`is_free()`

Return `True` if the symbol is referenced in its block, but not assigned to.

`is_assigned()`

Return `True` if the symbol is assigned to in its block.

`is_namespace()`

Return `True` if name binding introduces new namespace.

If the name is used as the target of a function or class statement, this will be true.

For example:

```
>>> table = symtable.symtable("def some_func() :  
>>> table.lookup("some_func").is_namespace()  
True
```

Note that a single name can be bound to multiple objects. If the result is `True`, the name may also be bound to other objects, like an int or list, that does not introduce a new namespace.

`get_namespaces()`

Return a list of namespaces bound to this name.

`get_namespace()`

Return the namespace bound to this name. If more than

one or no namespace is bound to this name, a `ValueError` is raised.

# `token` — Constants used with Python parse trees

**Source code:** [Lib/token.py](https://github.com/python/cpython/tree/3.12/Lib/token.py) [https://github.com/python/cpython/tree/3.12/Lib/token.py]

---

This module provides constants which represent the numeric values of leaf nodes of the parse tree (terminal tokens). Refer to the file `Grammar/Tokens` in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

The module also provides a mapping from numeric codes to names and some functions. The functions mirror definitions in the Python C header files.

`token.tok_name`

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.

`token.ISTERMINAL(x)`

Return `True` for terminal token values.

`token.ISNONTERMINAL(x)`

Return `True` for non-terminal token values.

`token.ISEOF(x)`

Return `True` if `x` is the marker indicating the end of input.

The token constants are:

token.ENDMARKER

token.NAME

token.NUMBER

token.STRING

token.NEWLINE

token.INDENT

token.DEDENT

token.LPAR

Token value for " ( ".

token.RPAR

Token value for ") ".

token.FSTRING\_START

token.FSTRING\_MIDDLE

token.FSTRING\_END

token.COMMENT

token.NL

token.ERRORTOKEN

`token.N_TOKENS`

`token.NT_OFFSET`

The following token type values aren't used by the C tokenizer but are needed for the `tokenize` module.

`token.COMMENT`

Token value used to indicate a comment.

`token.NL`

Token value used to indicate a non-terminating newline. The `NEWLINE` token indicates the end of a logical line of Python code; `NL` tokens are generated when a logical line of code is continued over multiple physical lines.

`token.ENCODING`

Token value that indicates the encoding used to decode the source bytes into text. The first token returned by `tokenize.tokenize()` will always be an `ENCODING` token.

`token.TYPE_COMMENT`

Token value indicating that a type comment was recognized. Such tokens are only produced when `ast.parse()` is invoked with `type_comments=True`.

*Changed in version 3.5:* Added `AWAIT` and `ASYNC` tokens.

*Changed in version 3.7:* Added `COMMENT`, `NL` and `ENCODING` tokens.

*Changed in version 3.7:* Removed `AWAIT` and `ASYNC` tokens. “async” and “await” are now tokenized as `NAME` tokens.

*Changed in version 3.8:* Added `TYPE_COMMENT`, `TYPE_IGNORE`, `COLONEQUAL`. Added `AWAIT` and `ASYNC` tokens back (they're needed to support parsing older Python versions for `ast.parse()` with `feature_version` set to 6 or lower).

# keyword — Testing for Python keywords

**Source code:** [Lib/keyword.py](https://github.com/python/cpython/tree/3.12/Lib/keyword.py) [https://github.com/python/cpython/tree/3.12/Lib/keyword.py]

---

This module allows a Python program to determine if a string is a [keyword](#) or [soft keyword](#).

`keyword.iskeyword(s)`

Return `True` if `s` is a Python [keyword](#).

`keyword.kwlist`

Sequence containing all the [keywords](#) defined for the interpreter. If any keywords are defined to only be active when particular `__future__` statements are in effect, these will be included as well.

`keyword.issoftkeyword(s)`

Return `True` if `s` is a Python [soft keyword](#).

*New in version 3.9.*

`keyword.softkwlist`

Sequence containing all the [soft keywords](#) defined for the interpreter. If any soft keywords are defined to only be active when particular `__future__` statements are in effect, these will be included as well.

*New in version 3.9.*

# tokenize — Tokenizer for Python source

**Source code:** [Lib/tokenize.py](https://github.com/python/cpython/tree/3.12/Lib/tokenize.py) [https://github.com/python/cpython/tree/3.12/Lib/tokenize.py]

---

The `tokenize` module provides a lexical scanner for Python source code, implemented in Python. The scanner in this module returns comments as tokens as well, making it useful for implementing “pretty-printers”, including colorizers for on-screen displays.

To simplify token stream handling, all `operator` and `delimiter` tokens and `Ellipsis` are returned using the generic `OP` token type. The exact type can be determined by checking the `exact_type` property on the `named tuple` returned from `tokenize.tokenize()`.

## Warning

Note that the functions in this module are only designed to parse syntactically valid Python code (code that does not raise when parsed using `ast.parse()`). The behavior of the functions in this module is **undefined** when providing invalid Python code and it can change at any point.

## Tokenizing Input

The primary entry point is a `generator`:

```
tokenize.tokenize(readline)
```

The `tokenize()` generator requires one argument, *readline*, which must be a callable object which provides the same

interface as the `io.IOBase.readline()` method of file objects. Each call to the function should return one line of input as bytes.

The generator produces 5-tuples with these members: the token type; the token string; a 2-tuple `(srow, scol)` of ints specifying the row and column where the token begins in the source; a 2-tuple `(erow, ecol)` of ints specifying the row and column where the token ends in the source; and the line on which the token was found. The line passed (the last tuple item) is the *physical* line. The 5 tuple is returned as a **named tuple** with the field names: `type` `string` `start` `end` `line`.

The returned **named tuple** has an additional property named `exact_type` that contains the exact operator type for **OP** tokens. For all other token types `exact_type` equals the named tuple `type` field.

*Changed in version 3.1:* Added support for named tuples.

*Changed in version 3.3:* Added support for `exact_type`.

**tokenize()** determines the source encoding of the file by looking for a UTF-8 BOM or encoding cookie, according to **PEP 263** [<https://peps.python.org/pep-0263/>].

`tokenize.generate_tokens(readline)`

Tokenize a source reading unicode strings instead of bytes.

Like **tokenize()**, the *readline* argument is a callable returning a single line of input. However, **generate\_tokens()** expects *readline* to return a str object rather than bytes.

The result is an iterator yielding named tuples, exactly like **tokenize()**. It does not yield an **ENCODING** token.

All constants from the **token** module are also exported from **tokenize**.

Another function is provided to reverse the tokenization process. This is useful for creating tools that tokenize a script, modify the token stream, and write back the modified script.

`tokenize.untokenize(iterable)`

Converts tokens back into Python source code. The *iterable* must return sequences with at least two elements, the token type and the token string. Any additional sequence elements are ignored.

The reconstructed script is returned as a single string. The result is guaranteed to tokenize back to match the input so that the conversion is lossless and round-trips are assured. The guarantee applies only to the token type and token string as the spacing between tokens (column positions) may change.

It returns bytes, encoded using the `ENCODING` token, which is the first token sequence output by `tokenize()`. If there is no encoding token in the input, it returns a str instead.

`tokenize()` needs to detect the encoding of source files it tokenizes. The function it uses to do this is available:

`tokenize.detect_encoding(readline)`

The `detect_encoding()` function is used to detect the encoding that should be used to decode a Python source file. It requires one argument, *readline*, in the same way as the `tokenize()` generator.

It will call *readline* a maximum of twice, and return the encoding used (as a string) and a list of any lines (not decoded from bytes) it has read in.

It detects the encoding from the presence of a UTF-8 BOM or an encoding cookie as specified in [PEP 263](https://peps.python.org/pep-0263/) [https://peps.python.org/pep-0263/]. If both a BOM and a cookie are present, but disagree, a `SyntaxError` will be raised. Note that if the BOM is found, `'utf-8-sig'` will be returned as an encoding.

If no encoding is specified, then the default of `'utf-8'` will be returned.

Use `open()` to open Python source files: it uses `detect_encoding()` to detect the file encoding.

`tokenize.open(filename)`

Open a file in read only mode using the encoding detected by `detect_encoding()`.

*New in version 3.2.*

*exception* `tokenize.TokenError`

Raised when either a docstring or expression that may be split over several lines is not completed anywhere in the file, for example:

```
"""Beginning of  
docstring
```

or:

```
[1,  
 2,  
 3
```

## Command-Line Usage

*New in version 3.3.*

The `tokenize` module can be executed as a script from the command line. It is as simple as:

```
python -m tokenize [-e] [filename.py]
```

The following options are accepted:

`-h, --help`

show this help message and exit

`-e, --exact`

display token names using the exact type

If `filename.py` is specified its contents are tokenized to stdout. Otherwise, tokenization is performed on stdin.

## Examples

Example of a script rewriter that transforms float literals into Decimal objects:

```
from tokenize import tokenize, untokenize, NUMBER, STRING
from io import BytesIO
```

```
def decistmt(s):
    """Substitute Decimals for floats in a string of statements
```

```
>>> from decimal import Decimal
>>> s = 'print(+21.3e-5*-.1234/81.7) '
>>> decistmt(s)
"print (+Decimal ('21.3e-5')*-Decimal ('.1234')/Decimal ('81.7'))"
```

The format of the exponent is inherited from the platform. Known cases are "e-007" (Windows) and "e-07" (not Windows). We're only showing 12 digits, and the 13th isn't close. The rest of the output should be platform-independent.

```
>>> exec(s) #doctest: +ELLIPSIS
-3.21716034272e-0...7
```

Output from calculations with Decimal should be identical on all platforms.

```
>>> exec(decistmt(s))
-3.217160342717258261933904529E-7
"""
result = []
g = tokenize(BytesIO(s.encode('utf-8')).readline) # Generator of
```

```

for toknum, tokval, _, _, _ in g:
    if toknum == NUMBER and '.' in tokval: # replace
        result.extend([
            (NAME, 'Decimal'),
            (OP, '('),
            (STRING, repr(tokval)),
            (OP, ')')
        ])
    else:
        result.append((toknum, tokval))
return untokenize(result).decode('utf-8')

```

Example of tokenizing from the command line. The script:

```

def say_hello():
    print("Hello, World!")

say_hello()

```

will be tokenized to the following output where the first column is the range of the line/column coordinates where the token is found, the second column is the name of the token, and the final column is the value of the token (if any)

```

$ python -m tokenize hello.py
0,0-0,0:      ENCODING      'utf-8'
1,0-1,3:      NAME          'def'
1,4-1,13:     NAME          'say_hello'
1,13-1,14:    OP            '('
1,14-1,15:    OP            ')'
1,15-1,16:    OP            ':'
1,16-1,17:    NEWLINE       '\n'
2,0-2,4:      INDENT        '    '
2,4-2,9:      NAME          'print'
2,9-2,10:     OP            '('
2,10-2,25:    STRING        '"Hello, World!'"
2,25-2,26:    OP            ')'
2,26-2,27:    NEWLINE       '\n'
3,0-3,1:      NL            '\n'

```

4,0-4,0:	DEDENT	' '
4,0-4,9:	NAME	'say_hello'
4,9-4,10:	OP	'('
4,10-4,11:	OP	')'
4,11-4,12:	NEWLINE	'\n'
5,0-5,0:	ENDMARKER	' '

The exact token type names can be displayed using the **-e** option:

```
$ python -m tokenize -e hello.py
0,0-0,0:      ENCODING      'utf-8'
1,0-1,3:      NAME          'def'
1,4-1,13:     NAME          'say_hello'
1,13-1,14:    LPAR          '('
1,14-1,15:    RPAR          ')'
1,15-1,16:    COLON         ':'
1,16-1,17:    NEWLINE       '\n'
2,0-2,4:      INDENT        '    '
2,4-2,9:      NAME          'print'
2,9-2,10:     LPAR          '('
2,10-2,25:    STRING        '"Hello, World!'"
2,25-2,26:    RPAR          ')'
2,26-2,27:    NEWLINE       '\n'
3,0-3,1:      NL           '\n'
4,0-4,0:      DEDENT        ''
4,0-4,9:      NAME          'say_hello'
4,9-4,10:     LPAR          '('
4,10-4,11:    RPAR          ')'
4,11-4,12:    NEWLINE       '\n'
5,0-5,0:      ENDMARKER    ''
```

Example of tokenizing a file programmatically, reading unicode strings instead of bytes with **generate\_tokens()**:

```
import tokenize

with tokenize.open('hello.py') as f:
    tokens = tokenize.generate_tokens(f.readline)
    for token in tokens:
```

```
print(token)
```

Or reading bytes directly with `tokenize()`:

```
import tokenize
```

```
with open('hello.py', 'rb') as f:
    tokens = tokenize.tokenize(f.readline)
    for token in tokens:
        print(token)
```

# tabnanny — Detection of ambiguous indentation

**Source code:** [Lib/tabnanny.py](https://github.com/python/cpython/tree/3.12/Lib/tabnanny.py) [https://github.com/python/cpython/tree/3.12/Lib/tabnanny.py]

---

For the time being this module is intended to be called as a script. However it is possible to import it into an IDE and use the function `check()` described below.

## Note

The API provided by this module is likely to change in future releases; such changes may not be backward compatible.

`tabnanny.check(file_or_dir)`

If *file\_or\_dir* is a directory and not a symbolic link, then recursively descend the directory tree named by *file\_or\_dir*, checking all `.py` files along the way. If *file\_or\_dir* is an ordinary Python source file, it is checked for whitespace related problems. The diagnostic messages are written to standard output using the `print()` function.

`tabnanny.verbose`

Flag indicating whether to print verbose messages. This is incremented by the `-v` option if called as a script.

`tabnanny.filename_only`

Flag indicating whether to print only the filenames of files containing whitespace related problems. This is set to true by the `-q` option if called as a script.

*exception* `tabnanny.NannyNag`

Raised by `process_tokens()` if detecting an ambiguous indent. Captured and handled in `check()`.

`tabnanny.process_tokens(tokens)`

This function is used by `check()` to process tokens generated by the `tokenize` module.

**Module** `tokenize`

Lexical scanner for Python source code.

# pyclbr — Python module browser support

**Source code:** [Lib/pyclbr.py](https://github.com/python/cpython/tree/3.12/Lib/pyclbr.py) [https://github.com/python/cpython/tree/3.12/Lib/pyclbr.py]

---

The **pyclbr** module provides limited information about the functions, classes, and methods defined in a Python-coded module. The information is sufficient to implement a module browser. The information is extracted from the Python source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

`pyclbr.readmodule(module, path = None)`

Return a dictionary mapping module-level class names to class descriptors. If possible, descriptors for imported base classes are included. Parameter *module* is a string with the name of the module to read; it may be the name of a module within a package. If given, *path* is a sequence of directory paths prepended to `sys.path`, which is used to locate the module source code.

This function is the original interface and is only kept for back compatibility. It returns a filtered version of the following.

`pyclbr.readmodule_ex(module, path = None)`

Return a dictionary-based tree containing a function or class descriptors for each function and class defined in the module with a `def` or `class` statement. The returned dictionary maps module-level function and class names to their descriptors. Nested objects are entered into the children

dictionary of their parent. As with `readmodule`, *module* names the module to be read and *path* is prepended to `sys.path`. If the module being read is a package, the returned dictionary has a key `'__path__'` whose value is a list containing the package search path.

*New in version 3.7:* Descriptors for nested definitions. They are accessed through the new `children` attribute. Each has a new `parent` attribute.

The descriptors returned by these functions are instances of `Function` and `Class` classes. Users are not expected to create instances of these classes.

## Function Objects

Class **`Function`** instances describe functions defined by `def` statements. They have the following attributes:

`Function.file`

Name of the file in which the function is defined.

`Function.module`

The name of the module defining the function described.

`Function.name`

The name of the function.

`Function.lineno`

The line number in the file where the definition starts.

`Function.parent`

For top-level functions, `None`. For nested functions, the parent.

*New in version 3.7.*

`Function.children`

A dictionary mapping names to descriptors for nested functions and classes.

*New in version 3.7.*

Function.is\_async

True for functions that are defined with the `async` prefix, False otherwise.

*New in version 3.10.*

## Class Objects

Class **Class** instances describe classes defined by class statements. They have the same attributes as Functions and two more.

Class.file

Name of the file in which the class is defined.

Class.module

The name of the module defining the class described.

Class.name

The name of the class.

Class.lineno

The line number in the file where the definition starts.

Class.parent

For top-level classes, None. For nested classes, the parent.

*New in version 3.7.*

Class.children

A dictionary mapping names to descriptors for nested functions and classes.

*New in version 3.7.*

## Class.super

A list of **Class** objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by `readmodule_ex()` are listed as a string with the class name instead of as **Class** objects.

## Class.methods

A dictionary mapping method names to line numbers. This can be derived from the newer children dictionary, but remains for back-compatibility.

# py\_compile — Compile Python source files

**Source code:** [Lib/py\\_compile.py](#) [[https://github.com/python/cpython/tree/3.12/Lib/py\\_compile.py](https://github.com/python/cpython/tree/3.12/Lib/py_compile.py)]

---

The `py_compile` module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

*exception* `py_compile.PyCompileError`

Exception raised when an error occurs while attempting to compile the file.

`py_compile.compile(file, cfile=None, dfile=None, doraise=False, optimize=-1, invalidation_mode=PycInvalidationMode.TIMESTAMP, quiet=0)`

Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file named *file*. The byte-code is written to *cfile*, which defaults to the [PEP 3147](#) [<https://peps.python.org/pep-3147/>]/[PEP 488](#) [<https://peps.python.org/pep-0488/>] path, ending in `.pyc`. For example, if *file* is `/foo/bar/baz.py` *cfile* will default to `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. If *dfile* is specified, it is used instead of *file* as the name of the source file from which source lines are obtained for display in exception tracebacks. If *doraise* is true, a `PyCompileError` is raised when an error is encountered while compiling *file*. If *doraise* is false (the default), an error string is written to

`sys.stderr`, but no exception is raised. This function returns the path to byte-compiled file, i.e. whatever *cfile* value was used.

The *doraise* and *quiet* arguments determine how errors are handled while compiling file. If *quiet* is 0 or 1, and *doraise* is false, the default behaviour is enabled: an error string is written to `sys.stderr`, and the function returns `None` instead of a path. If *doraise* is true, a `PyCompileError` is raised instead. However if *quiet* is 2, no message is written, and *doraise* has no effect.

If the path that *cfile* becomes (either explicitly specified or computed) is a symlink or non-regular file, `FileExistsError` will be raised. This is to act as a warning that import will turn those paths into regular files if it is allowed to write byte-compiled files to those paths. This is a side-effect of import using file renaming to place the final byte-compiled file into place to prevent concurrent file writing issues.

*optimize* controls the optimization level and is passed to the built-in `compile()` function. The default of `-1` selects the optimization level of the current interpreter.

*invalidation\_mode* should be a member of the `PycInvalidationMode` enum and controls how the generated bytecode cache is invalidated at runtime. The default is `PycInvalidationMode.CHECKED_HASH` if the `SOURCE_DATE_EPOCH` environment variable is set, otherwise the default is `PycInvalidationMode.TIMESTAMP`.

*Changed in version 3.2:* Changed default value of *cfile* to be [PEP 3147](https://peps.python.org/pep-3147/) [https://peps.python.org/pep-3147/] -compliant. Previous default was `file + 'c' ('o' if optimization was enabled)`. Also added the *optimize* parameter.

*Changed in version 3.4:* Changed code to use `importlib` for the byte-code cache file writing. This means file creation/writing semantics now match what `importlib` does, e.g. permissions, write-and-move semantics, etc. Also added the

caveat that `FileExistsError` is raised if `cfile` is a symlink or non-regular file.

*Changed in version 3.7:* The `invalidation_mode` parameter was added as specified in [PEP 552](https://peps.python.org/pep-0552/) [https://peps.python.org/pep-0552/]. If the `SOURCE_DATE_EPOCH` environment variable is set, `invalidation_mode` will be forced to `PycInvalidationMode.CHECKED_HASH`.

*Changed in version 3.7.2:* The `SOURCE_DATE_EPOCH` environment variable no longer overrides the value of the `invalidation_mode` argument, and determines its default value instead.

*Changed in version 3.8:* The `quiet` parameter was added.

`class py_compile.PycInvalidationMode`

An enumeration of possible methods the interpreter can use to determine whether a bytecode file is up to date with a source file. The `.pyc` file indicates the desired invalidation mode in its header. See [Cached bytecode invalidation](#) for more information on how Python invalidates `.pyc` files at runtime.

*New in version 3.7.*

**TIMESTAMP**

The `.pyc` file includes the timestamp and size of the source file, which Python will compare against the metadata of the source file at runtime to determine if the `.pyc` file needs to be regenerated.

**CHECKED\_HASH**

The `.pyc` file includes a hash of the source file content, which Python will compare against the source at runtime to determine if the `.pyc` file needs to be regenerated.

**UNCHECKED\_HASH**

Like [CHECKED\\_HASH](#), the `.pyc` file includes a hash of the source file content. However, Python will at runtime assume the `.pyc` file is up to date and not validate the `.pyc` against the source file at all.

This option is useful when the `.pycs` are kept up to date by some system external to Python like a build system.

## Command-Line Interface

This module can be invoked as a script to compile several source files. The files named in *filenames* are compiled and the resulting bytecode is cached in the normal manner. This program does not search a directory structure to locate source files; it only compiles files named explicitly. The exit status is nonzero if one of the files could not be compiled.

<file> ... <fileN>

-

Positional arguments are files to compile. If - is the only parameter, the list of files is taken from standard input.

-q, --quiet

Suppress errors output.

*Changed in version 3.2:* Added support for -.

*Changed in version 3.10:* Added support for [-q](#).

See also

Module [compileall](#)

Utilities to compile all Python source files in a directory tree.

# compileall — Byte-compile Python libraries

**Source code:** [Lib/compileall.py](https://github.com/python/cpython/tree/3.12/Lib/compileall.py) [https://github.com/python/cpython/tree/3.12/Lib/compileall.py]

---

This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree. This module can be used to create the cached byte-code files at library installation time, which makes them available for use even by users who don't have write permission to the library directories.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

## Command-line use

This module can work as a script (using **python -m compileall**) to compile Python sources.

directory ...

file ...

Positional arguments are files to compile or directories that contain source files, traversed recursively. If no argument is given, behave as if the command line was `-l`  
*<directories from sys.path>*.

-l

Do not recurse into subdirectories, only compile source code files directly contained in the named or implied directories.

-f

Force rebuild even if timestamps are up-to-date.

-q

Do not print the list of files compiled. If passed once, error messages will still be printed. If passed twice (-qq), all output is suppressed.

-d destdir

Directory prepended to the path to each file being compiled. This will appear in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

-s strip\_prefix

-p prepend\_prefix

Remove (-s) or append (-p) the given prefix of paths recorded in the `.pyc` files. Cannot be combined with `-d`.

-x regex

regex is used to search the full path to each file considered for compilation, and if the regex produces a match, the file is skipped.

-i list

Read the file `list` and add each line that it contains to the list of files and directories to compile. If `list` is `-`, read lines from `stdin`.

-b

Write the byte-code files to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](https://peps.python.org/pep-3147/) [https://peps.python.org/pep-3147/] locations and names, which allows byte-code files from multiple versions of Python

to coexist.

**-r**

Control the maximum recursion level for subdirectories. If this is given, then **-l** option will not be taken into account. **python -m compileall <directory> -r 0** is equivalent to **python -m compileall <directory> -l**.

**-j N**

Use *N* workers to compile the files within the given directory. If 0 is used, then the result of `os.cpu_count()` will be used.

**--invalidation-mode [timestamp|checked-hash|unchecked-hash]**

Control how the generated byte-code files are invalidated at runtime. The `timestamp` value, means that `.pyc` files with the source timestamp and size embedded will be generated. The `checked-hash` and `unchecked-hash` values cause hash-based pycs to be generated. Hash-based pycs embed a hash of the source file contents rather than a timestamp. See [Cached bytecode invalidation](#) for more information on how Python validates bytecode cache files at runtime. The default is `timestamp` if the `SOURCE_DATE_EPOCH` environment variable is not set, and `checked-hash` if the `SOURCE_DATE_EPOCH` environment variable is set.

**-o level**

Compile with the given optimization level. May be used multiple times to compile for multiple levels at a time (for example, `compileall -o 1 -o 2`).

**-e dir**

Ignore symlinks pointing outside the given directory.

**--hardlink-dupes**

If two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

*Changed in version 3.2:* Added the `-i`, `-b` and `-h` options.

*Changed in version 3.5:* Added the `-j`, `-r`, and `-qq` options. `-q` option was changed to a multilevel value. `-b` will always produce a byte-code file ending in `.pyc`, never `.pyo`.

*Changed in version 3.7:* Added the `--invalidation-mode` option.

*Changed in version 3.9:* Added the `-s`, `-p`, `-e` and `--hardlink-dupes` options. Raised the default recursion limit from 10 to `sys.getrecursionlimit()`. Added the possibility to specify the `-o` option multiple times.

There is no command-line option to control the optimization level used by the `compile()` function, because the Python interpreter itself already provides the option: **`python -O -m compileall`**.

Similarly, the `compile()` function respects the `sys.pycache_prefix` setting. The generated bytecode cache will only be useful if `compile()` is run with the same `sys.pycache_prefix` (if any) that will be used at runtime.

## Public functions

`compileall.compile_dir(dir, maxlevels=sys.getrecursionlimit(), ddir=None, force=False, rx=None, quiet=0, legacy=False, optimize=-1, workers=1, invalidation_mode=None, *, stripdir=None, prependdir=None, limit_sl_dest=None, hardlink_dupes=False)`

Recursively descend the directory tree named by *dir*, compiling all `.py` files along the way. Return a true value if all the files compiled successfully, and a false value otherwise.

The *maxlevels* parameter is used to limit the depth of the recursion; it defaults to `sys.getrecursionlimit()`.

If *ddir* is given, it is prepended to the path to each file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in

tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *force* is true, modules are re-compiled even if the timestamps are up to date.

If *rx* is given, its `search` method is called on the complete path to each file considered for compilation, and if it returns a true value, the file is skipped. This can be used to exclude files matching a regular expression, given as a [re.Pattern](#) object.

If *quiet* is `False` or `0` (the default), the filenames and other information are printed to standard out. Set to `1`, only errors are printed. Set to `2`, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](#) [<https://peps.python.org/pep-3147/>] locations and names, which allows byte-code files from multiple versions of Python to coexist.

*optimize* specifies the optimization level for the compiler. It is passed to the built-in `compile()` function. Accepts also a sequence of optimization levels which lead to multiple compilations of one `.py` file in one call.

The argument *workers* specifies how many workers are used to compile files in parallel. The default is to not use multiple workers. If the platform can't use multiple workers and *workers* argument is given, then sequential compilation will be used as a fallback. If *workers* is `0`, the number of cores in the system is used. If *workers* is lower than `0`, a `ValueError` will be raised.

*invalidation\_mode* should be a member of the `py_compile.PycInvalidationMode` enum and controls how the generated pycs are invalidated at runtime.

The *stripdir*, *prependdir* and *limit\_sl\_dest* arguments correspond

to the `-s`, `-p` and `-e` options described above. They may be specified as `str` or `os.PathLike`.

If `hardlink_dupes` is true and two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

*Changed in version 3.2:* Added the `legacy` and `optimize` parameter.

*Changed in version 3.5:* Added the `workers` parameter.

*Changed in version 3.5:* `quiet` parameter was changed to a multilevel value.

*Changed in version 3.5:* The `legacy` parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of `optimize` is.

*Changed in version 3.6:* Accepts a `path-like object`.

*Changed in version 3.7:* The `invalidation_mode` parameter was added.

*Changed in version 3.7.2:* The `invalidation_mode` parameter's default value is updated to `None`.

*Changed in version 3.8:* Setting `workers` to 0 now chooses the optimal number of cores.

*Changed in version 3.9:* Added `stripdir`, `prependdir`, `limit_sl_dest` and `hardlink_dupes` arguments. Default value of `maxlevels` was changed from 10 to `sys.getrecursionlimit()`

```
compileall.compile_file(fullname, ddir=None, force=False,
rx=None, quiet=0, legacy=False, optimize=-1,
invalidation_mode=None, *, stripdir=None, prependdir=None,
limit_sl_dest=None, hardlink_dupes=False)
```

Compile the file with path `fullname`. Return a true value if the file compiled successfully, and a false value otherwise.

If *ddir* is given, it is prepended to the path to the file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *rx* is given, its `search` method is passed the full path name to the file being compiled, and if it returns a true value, the file is not compiled and `True` is returned. This can be used to exclude files matching a regular expression, given as a [`re.Pattern`](#) object.

If *quiet* is `False` or `0` (the default), the filenames and other information are printed to standard out. Set to `1`, only errors are printed. Set to `2`, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](https://peps.python.org/pep-3147/) [https://peps.python.org/pep-3147/] locations and names, which allows byte-code files from multiple versions of Python to coexist.

*optimize* specifies the optimization level for the compiler. It is passed to the built-in `compile()` function. Accepts also a sequence of optimization levels which lead to multiple compilations of one `.py` file in one call.

*invalidation\_mode* should be a member of the [`py\_compile.PycInvalidationMode`](#) enum and controls how the generated pycs are invalidated at runtime.

The *stripdir*, *prependdir* and *limit\_sl\_dest* arguments correspond to the `-s`, `-p` and `-e` options described above. They may be specified as `str` or [`os.PathLike`](#).

If *hardlink\_dupes* is true and two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

*New in version 3.2.*

*Changed in version 3.5:* *quiet* parameter was changed to a multilevel value.

*Changed in version 3.5:* The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

*Changed in version 3.7:* The *invalidation\_mode* parameter was added.

*Changed in version 3.7.2:* The *invalidation\_mode* parameter's default value is updated to `None`.

*Changed in version 3.9:* Added *stripdir*, *prependdir*, *limit\_sl\_dest* and *hardlink\_dupes* arguments.

```
compileall.compile_path(skip_curdir=True, maxlevels=0,  
force=False, quiet=0, legacy=False, optimize=-1,  
invalidation_mode=None)
```

Byte-compile all the `.py` files found along `sys.path`. Return a true value if all the files compiled successfully, and a false value otherwise.

If *skip\_curdir* is true (the default), the current directory is not included in the search. All other parameters are passed to the `compile_dir()` function. Note that unlike the other compile functions, `maxlevels` defaults to `0`.

*Changed in version 3.2:* Added the *legacy* and *optimize* parameter.

*Changed in version 3.5:* *quiet* parameter was changed to a multilevel value.

*Changed in version 3.5:* The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

*Changed in version 3.7:* The *invalidation\_mode* parameter was added.

*Changed in version 3.7.2:* The `invalidation_mode` parameter's default value is updated to `None`.

To force a recompile of all the `.py` files in the `Lib/` subdirectory and all its subdirectories:

```
import compileall

compileall.compile_dir('Lib/', force=True)

# Perform same compilation, excluding files in .svn dire
import re
compileall.compile_dir('Lib/', rx=re.compile(r'[/\\][.]s

# pathlib.Path objects can also be used.
import pathlib
compileall.compile_dir(pathlib.Path('Lib/'), force=True)
```

**See also**

**Module** [py\\_compile](#)

Byte-compile a single source file.

# dis — Disassembler for Python bytecode

**Source code:** [Lib/dis.py](https://github.com/python/cpython/tree/3.12/Lib/dis.py) [https://github.com/python/cpython/tree/3.12/Lib/dis.py]

---

The **dis** module supports the analysis of CPython **bytecode** by disassembling it. The CPython bytecode which this module takes as an input is defined in the file `Include/opcode.h` and used by the compiler and the interpreter.

**CPython implementation detail:** Bytecode is an implementation detail of the CPython interpreter. No guarantees are made that bytecode will not be added, removed, or changed between versions of Python. Use of this module should not be considered to work across Python VMs or Python releases.

*Changed in version 3.6:* Use 2 bytes for each instruction. Previously the number of bytes varied by instruction.

*Changed in version 3.10:* The argument of jump, exception handling and loop instructions is now the instruction offset rather than the byte offset.

*Changed in version 3.11:* Some instructions are accompanied by one or more inline cache entries, which take the form of **CACHE** instructions. These instructions are hidden by default, but can be shown by passing `show_caches=True` to any **dis** utility. Furthermore, the interpreter now adapts the bytecode to specialize it for different runtime conditions. The adaptive bytecode can be shown by passing `adaptive=True`.

Example: Given the function **myfunc()**:

```
def myfunc(alist):
```

```
return len(alist)
```

the following command can be used to display the disassembly of **myfunc()**:

```
>>> dis.dis(myfunc)
2              0 RESUME              0

3              2 LOAD_GLOBAL          1 (NULL + len)
              12 LOAD_FAST            0 (alist)
              14 CALL              1
              22 RETURN_VALUE
```

(The “2” is a line number).

## Command-line interface

The **dis** module can be invoked as a script from the command line:

```
python -m dis [-h] [infile]
```

The following options are accepted:

**-h, --help**

Display usage and exit.

If *infile* is specified, its disassembled code will be written to stdout. Otherwise, disassembly is performed on compiled source code recieved from stdin.

## Bytecode analysis

*New in version 3.4.*

The bytecode analysis API allows pieces of Python code to be wrapped in a **Bytecode** object that provides easy access to details of the compiled code.

```
class dis.Bytecode(x, *, first_line=None, current_offset=None,
show_caches=False, adaptive=False)
```

Analyse the bytecode corresponding to a function, generator, asynchronous generator, coroutine, method, string of source code, or a code object (as returned by `compile()`).

This is a convenience wrapper around many of the functions listed below, most notably `get_instructions()`, as iterating over a `Bytecode` instance yields the bytecode operations as `Instruction` instances.

If `first_line` is not `None`, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

If `current_offset` is not `None`, it refers to an instruction offset in the disassembled code. Setting this means `dis()` will display a “current instruction” marker against the specified opcode.

If `show_caches` is `True`, `dis()` will display inline cache entries used by the interpreter to specialize the bytecode.

If `adaptive` is `True`, `dis()` will display specialized bytecode that may be different from the original bytecode.

```
classmethod from_traceback(tb, *, show_caches=False)
```

Construct a `Bytecode` instance from the given traceback, setting `current_offset` to the instruction responsible for the exception.

`codeobj`

The compiled code object.

`first_line`

The first source line of the code object (if available)

`dis()`

Return a formatted view of the bytecode operations (the same as printed by `dis.dis()`, but returned as a multi-line string).

`info()`

Return a formatted multi-line string with detailed information about the code object, like `code_info()`.

*Changed in version 3.7:* This can now handle coroutine and asynchronous generator objects.

*Changed in version 3.11:* Added the *show\_caches* and *adaptive* parameters.

Example:

```
>>> bytecode = dis.Bytecode(myfunc)
>>> for instr in bytecode:
...     print(instr.opname)
...
RESUME
LOAD_GLOBAL
LOAD_FAST
CALL
RETURN_VALUE
```

## Analysis functions

The `dis` module also defines the following analysis functions that convert the input directly to the desired output. They can be useful if only a single operation is being performed, so the intermediate analysis object isn't useful:

`dis.code_info(x)`

Return a formatted multi-line string with detailed code object information for the supplied function, generator, asynchronous generator, coroutine, method, source code string or code object.

Note that the exact contents of code info strings are highly implementation dependent and they may change arbitrarily across Python VMs or Python releases.

*New in version 3.2.*

*Changed in version 3.7:* This can now handle coroutine and asynchronous generator objects.

`dis.show_code(x, *, file=None)`

Print detailed code object information for the supplied function, method, source code string or code object to *file* (or `sys.stdout` if *file* is not specified).

This is a convenient shorthand for `print(code_info(x), file=file)`, intended for interactive exploration at the interpreter prompt.

*New in version 3.2.*

*Changed in version 3.4:* Added *file* parameter.

`dis.dis(x=None, *, file=None, depth=None, show_caches=False, adaptive=False)`

Disassemble the *x* object. *x* can denote either a module, a class, a method, a function, a generator, an asynchronous generator, a coroutine, a code object, a string of source code or a byte sequence of raw bytecode. For a module, it disassembles all functions. For a class, it disassembles all methods (including class and static methods). For a code object or sequence of raw bytecode, it prints one line per bytecode instruction. It also recursively disassembles nested code objects. These can include generator expressions, nested functions, the bodies of nested classes, and the code objects used for [annotation scopes](#). Strings are first compiled to code objects with the `compile()` built-in function before being disassembled. If no object is provided, this function disassembles the last traceback.

The disassembly is written as text to the supplied *file*

argument if provided and to `sys.stdout` otherwise.

The maximal depth of recursion is limited by *depth* unless it is `None`. `depth=0` means no recursion.

If *show\_caches* is `True`, this function will display inline cache entries used by the interpreter to specialize the bytecode.

If *adaptive* is `True`, this function will display specialized bytecode that may be different from the original bytecode.

*Changed in version 3.4:* Added *file* parameter.

*Changed in version 3.7:* Implemented recursive disassembling and added *depth* parameter.

*Changed in version 3.7:* This can now handle coroutine and asynchronous generator objects.

*Changed in version 3.11:* Added the *show\_caches* and *adaptive* parameters.

```
dis.distrib(tb=None, *, file=None, show_caches=False,  
adaptive=False)
```

Disassemble the top-of-stack function of a traceback, using the last traceback if none was passed. The instruction causing the exception is indicated.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

*Changed in version 3.4:* Added *file* parameter.

*Changed in version 3.11:* Added the *show\_caches* and *adaptive* parameters.

```
dis.disassemble(code, lasti=-1, *, file=None, show_caches=False,  
adaptive=False)
```

```
dis.disco(code, lasti=-1, *, file=None, show_caches=False,  
adaptive=False)
```

Disassemble a code object, indicating the last instruction if *lasti* was provided. The output is divided in the following columns:

1. the line number, for the first instruction of each line
2. the current instruction, indicated as `-->`,
3. a labelled instruction, indicated with `>>`,
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.

The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

*Changed in version 3.4:* Added *file* parameter.

*Changed in version 3.11:* Added the *show\_caches* and *adaptive* parameters.

```
dis.get_instructions(x, *, first_line=None, show_caches=False,
adaptive=False)
```

Return an iterator over the instructions in the supplied function, method, source code string or code object.

The iterator generates a series of **Instruction** named tuples giving the details of each operation in the supplied code.

If *first\_line* is not `None`, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

The *show\_caches* and *adaptive* parameters work as they do in **dis()**.

*New in version 3.4.*

*Changed in version 3.11:* Added the `show_caches` and `adaptive` parameters.

`dis.findlinestarts(code)`

This generator function uses the `co_lines` method of the code object `code` to find the offsets which are starts of lines in the source code. They are generated as `(offset, lineno)` pairs.

*Changed in version 3.6:* Line numbers can be decreasing. Before, they were always increasing.

*Changed in version 3.10:* The [PEP 626](https://peps.python.org/pep-0626/) `co_lines` method is used instead of the `co_firstlineno` and `co_notab` attributes of the code object.

`dis.findlabels(code)`

Detect all offsets in the raw compiled bytecode string `code` which are jump targets, and return a list of these offsets.

`dis.stack_effect(opcode, oparg=None, *, jump=None)`

Compute the stack effect of `opcode` with argument `oparg`.

If the code has a jump target and `jump` is `True`, `stack_effect()` will return the stack effect of jumping. If `jump` is `False`, it will return the stack effect of not jumping. And if `jump` is `None` (default), it will return the maximal stack effect of both cases.

*New in version 3.4.*

*Changed in version 3.8:* Added `jump` parameter.

## Python Bytecode Instructions

The `get_instructions()` function and `Bytecode` class

provide details of bytecode instructions as [Instruction](#) instances:

*class* `dis.Instruction`

Details for a bytecode operation

`opcode`

numeric code for operation, corresponding to the opcode values listed below and the bytecode values in the [Opcode collections](#).

`opname`

human readable name for operation

`arg`

numeric argument to operation (if any), otherwise `None`

`argval`

resolved arg value (if any), otherwise `None`

`argrepr`

human readable description of operation argument (if any), otherwise an empty string.

`offset`

start index of operation within bytecode sequence

`starts_line`

line started by this opcode (if any), otherwise `None`

`is_jump_target`

`True` if other code jumps to here, otherwise `False`

`positions`

[dis.Positions](#) object holding the start and end locations that are covered by this instruction.

*New in version 3.4.*

*Changed in version 3.11:* Field `positions` is added.

`class dis.Positions`

In case the information is not available, some fields might be `None`.

`lineno`

`end_lineno`

`col_offset`

`end_col_offset`

*New in version 3.11.*

The Python compiler currently generates the following bytecode instructions.

## General instructions

In the following, We will refer to the interpreter stack as `STACK` and describe operations on it as if it was a Python list. The top of the stack corresponds to `STACK[-1]` in this language.

**NOP**

Do nothing code. Used as a placeholder by the bytecode optimizer, and to generate line tracing events.

**POP\_TOP**

Removes the top-of-stack item:

```
STACK.pop()
```

**END\_FOR**

Removes the top two values from the stack. Equivalent to `POP_TOP`; `POP_TOP`. Used to clean up at the end of loops,

hence the name.

*New in version 3.12.*

## COPY(*i*)

Push the *i*-th item to the top of the stack without removing it from its original location:

```
assert i > 0
STACK.append(STACK[-i])
```

*New in version 3.11.*

## SWAP(*i*)

Swap the top of the stack with the *i*-th element:

```
STACK[-i], STACK[-1] = stack[-1], STACK[-i]
```

*New in version 3.11.*

## CACHE

Rather than being an actual instruction, this opcode is used to mark extra space for the interpreter to cache useful data directly in the bytecode itself. It is automatically hidden by all `dis` utilities, but can be viewed with `show_caches=True`.

Logically, this space is part of the preceding instruction. Many opcodes expect to be followed by an exact number of caches, and will instruct the interpreter to skip over them at runtime.

Populated caches can look like arbitrary instructions, so great care should be taken when reading or modifying raw, adaptive bytecode containing quickened data.

*New in version 3.11.*

## Unary operations

Unary operations take the top of the stack, apply the operation, and

push the result back on the stack.

#### UNARY\_NEGATIVE

Implements `STACK[-1] = -STACK[-1]`.

#### UNARY\_NOT

Implements `STACK[-1] = not STACK[-1]`.

#### UNARY\_INVERT

Implements `STACK[-1] = ~STACK[-1]`.

#### GET\_ITER

Implements `STACK[-1] = iter(STACK[-1])`.

#### GET\_YIELD\_FROM\_ITER

If `STACK[-1]` is a [generator iterator](#) or [coroutine](#) object it is left as is. Otherwise, implements `STACK[-1] = iter(STACK[-1])`.

*New in version 3.5.*

### Binary and in-place operations

Binary operations remove the top two items from the stack (`STACK[-1]` and `STACK[-2]`). They perform the operation, then put the result back on the stack.

In-place operations are like binary operations, but the operation is done in-place when `STACK[-2]` supports it, and the resulting `STACK[-1]` may be (but does not have to be) the original `STACK[-2]`.

#### BINARY\_OP(*op*)

Implements the binary and in-place operators (depending on the value of *op*):

```
rhs = STACK.pop()
lhs = STACK.pop()
STACK.append(lhs op rhs)
```

*New in version 3.11.*

## BINARY\_SUBSCR

Implements:

```
key = STACK.pop()
container = STACK.pop()
STACK.append(container[key])
```

## STORE\_SUBSCR

Implements:

```
key = STACK.pop()
container = STACK.pop()
value = STACK.pop()
container[key] = value
```

## DELETE\_SUBSCR

Implements:

```
key = STACK.pop()
container = STACK.pop()
del container[key]
```

## BINARY\_SLICE

Implements:

```
end = STACK.pop()
start = STACK.pop()
container = STACK.pop()
STACK.append(container[start:end])
```

*New in version 3.12.*

## STORE\_SLICE

Implements:

```
end = STACK.pop()
```

```

start = STACK.pop()
container = STACK.pop()
values = STACK.pop()
container[start:end] = value

```

*New in version 3.12.*

## Coroutine opcodes

### GET\_AWAITABLE(*where*)

Implements `STACK[-1] = get_awaitable(STACK[-1])`, where `get_awaitable(o)` returns `o` if `o` is a coroutine object or a generator object with the `CO_ITERABLE_COROUTINE` flag, or resolves `o.__await__`.

If the `where` operand is nonzero, it indicates where the instruction occurs:

- 1: After a call to `__aenter__`
- 2: After a call to `__aexit__`

*New in version 3.5.*

*Changed in version 3.11:* Previously, this instruction did not have an `oparg`.

### GET\_AITER

Implements `STACK[-1] = STACK[-1].__aiter__()`.

*New in version 3.5.*

*Changed in version 3.7:* Returning awaitable objects from `__aiter__` is no longer supported.

### GET\_ANEXT

Implement

`STACK.append(get_awaitable(STACK[-1].__anext__()))` to the stack. See `GET_AWAITABLE` for details about `get_awaitable`.

*New in version 3.5.*

## END\_ASYNC\_FOR

Terminates an **async for** loop. Handles an exception raised when awaiting a next item. The stack contains the async iterable in `STACK[-2]` and the raised exception in `STACK[-1]`. Both are popped. If the exception is not **StopAsyncIteration**, it is re-raised.

*New in version 3.8.*

*Changed in version 3.11:* Exception representation on the stack now consist of one, not three, items.

## CLEANUP\_THROW

Handles an exception raised during a **throw()** or **close()** call through the current frame. If `STACK[-1]` is an instance of **StopIteration**, pop three values from the stack and push its `value` member. Otherwise, re-raise `STACK[-1]`.

*New in version 3.12.*

## BEFORE\_ASYNC\_WITH

Resolves `__aenter__` and `__aexit__` from `STACK[-1]`. Pushes `__aexit__` and result of `__aenter__()` to the stack:

```
STACK.extend((__aexit__, __aenter__()))
```

*New in version 3.5.*

## Miscellaneous opcodes

### SET\_ADD(i)

Implements:

```
item = STACK.pop()
set.add(STACK[-i], item)
```

Used to implement set comprehensions.

## LIST\_APPEND(*i*)

Implements:

```
item = STACK.pop()
list.append(STACK[-i], item)
```

Used to implement list comprehensions.

## MAP\_ADD(*i*)

Implements:

```
value = STACK.pop()
key = STACK.pop()
dict.__setitem__(STACK[-i], key, value)
```

Used to implement dict comprehensions.

*New in version 3.1.*

*Changed in version 3.8:* Map value is `STACK[-1]` and map key is `STACK[-2]`. Before, those were reversed.

For all of the [SET\\_ADD](#), [LIST\\_APPEND](#) and [MAP\\_ADD](#) instructions, while the added value or key/value pair is popped off, the container object remains on the stack so that it is available for further iterations of the loop.

## RETURN\_VALUE

Returns with `STACK[-1]` to the caller of the function.

## RETURN\_CONST(*consti*)

Returns with `co_consts[consti]` to the caller of the function.

*New in version 3.12.*

## YIELD\_VALUE

Yields `STACK.pop()` from a [generator](#).

*Changed in version 3.11:* oparg set to be the stack depth.

*Changed in version 3.12:* oparg set to be the exception block depth, for efficient closing of generators.

## SETUP\_ANNOTATIONS

Checks whether `__annotations__` is defined in `locals()`, if not it is set up to an empty dict. This opcode is only emitted if a class or module body contains [variable annotations](#) statically.

*New in version 3.6.*

## POP\_EXCEPT

Pops a value from the stack, which is used to restore the exception state.

*Changed in version 3.11:* Exception representation on the stack now consist of one, not three, items.

## RERAISE

Re-raises the exception currently on top of the stack. If oparg is non-zero, pops an additional value from the stack which is used to set `f_lasti` of the current frame.

*New in version 3.9.*

*Changed in version 3.11:* Exception representation on the stack now consist of one, not three, items.

## PUSH\_EXC\_INFO

Pops a value from the stack. Pushes the current exception to the top of the stack. Pushes the value originally popped back to the stack. Used in exception handlers.

*New in version 3.11.*

## CHECK\_EXC\_MATCH

Performs exception matching for `except`. Tests whether the

`STACK[-2]` is an exception matching `STACK[-1]`. Pops `STACK[-1]` and pushes the boolean result of the test.

*New in version 3.11.*

## CHECK\_EG\_MATCH

Performs exception matching for `except*`. Applies `split(STACK[-1])` on the exception group representing `STACK[-2]`.

In case of a match, pops two items from the stack and pushes the non-matching subgroup (`None` in case of full match) followed by the matching subgroup. When there is no match, pops one item (the match type) and pushes `None`.

*New in version 3.11.*

## WITH\_EXCEPT\_START

Calls the function in position 4 on the stack with arguments (`type`, `val`, `tb`) representing the exception at the top of the stack. Used to implement the call `context_manager.__exit__(*exc_info())` when an exception has occurred in a `with` statement.

*New in version 3.9.*

*Changed in version 3.11:* The `__exit__` function is in position 4 of the stack rather than 7. Exception representation on the stack now consist of one, not three, items.

## LOAD\_ASSERTION\_ERROR

Pushes `AssertionError` onto the stack. Used by the `assert` statement.

*New in version 3.9.*

## LOAD\_BUILD\_CLASS

Pushes `builtins.__build_class__()` onto the stack. It is later called to construct a class.

## BEFORE\_WITH

This opcode performs several operations before a with block starts. First, it loads `__exit__()` from the context manager and pushes it onto the stack for later use by `WITH_EXCEPT_START`. Then, `__enter__()` is called. Finally, the result of calling the `__enter__()` method is pushed onto the stack.

*New in version 3.11.*

## GET\_LEN

Perform `STACK.append(len(STACK[-1]))`.

*New in version 3.10.*

## MATCH\_MAPPING

If `STACK[-1]` is an instance of `collections.abc.Mapping` (or, more technically: if it has the `Py_TPFLAGS_MAPPING` flag set in its `tp_flags`), push `True` onto the stack. Otherwise, push `False`.

*New in version 3.10.*

## MATCH\_SEQUENCE

If `STACK[-1]` is an instance of `collections.abc.Sequence` and is *not* an instance of `str/bytes/bytearray` (or, more technically: if it has the `Py_TPFLAGS_SEQUENCE` flag set in its `tp_flags`), push `True` onto the stack. Otherwise, push `False`.

*New in version 3.10.*

## MATCH\_KEYS

`STACK[-1]` is a tuple of mapping keys, and `STACK[-2]` is the match subject. If `STACK[-2]` contains all of the keys in `STACK[-1]`, push a `tuple` containing the corresponding values. Otherwise, push `None`.

*New in version 3.10.*

*Changed in version 3.11:* Previously, this instruction also pushed a boolean value indicating success (`True`) or failure (`False`).

### STORE\_NAME(*namei*)

Implements `name = STACK.pop().namei` is the index of *name* in the attribute **co\_names** of the [code object](#). The compiler tries to use **STORE\_FAST** or **STORE\_GLOBAL** if possible.

### DELETE\_NAME(*namei*)

Implements `del name`, where *namei* is the index into **co\_names** attribute of the [code object](#).

### UNPACK\_SEQUENCE(*count*)

Unpacks `STACK[-1]` into *count* individual values, which are put onto the stack right-to-left. Require there to be exactly *count* values.:

```
assert (len(STACK[-1]) == count)
STACK.extend(STACK.pop()[:-count-1:-1])
```

### UNPACK\_EX(*counts*)

Implements assignment with a starred target: Unpacks an iterable in `STACK[-1]` into individual values, where the total number of values can be smaller than the number of items in the iterable: one of the new values will be a list of all leftover items.

The number of values before and after the list value is limited to 255.

The number of values before the list value is encoded in the argument of the opcode. The number of values after the list if any is encoded using an **EXTENDED\_ARG**. As a consequence, the argument can be seen as a two bytes values where the low byte of *counts* is the number of values before the list value, the high byte of *counts* the number of values after it.

The extracted values are put onto the stack right-to-left, i.e. `a, *b, c = d` will be stored after execution as `STACK.extend((a, b, c))`.

### STORE\_ATTR(*namei*)

Implements:

```
obj = STACK.pop()
value = STACK.pop()
obj.name = value
```

where *namei* is the index of name in **co\_names** of the [code object](#).

### DELETE\_ATTR(*namei*)

Implements:

```
obj = STACK.pop()
del obj.name
```

where *namei* is the index of name into **co\_names** of the [code object](#).

### STORE\_GLOBAL(*namei*)

Works as [STORE\\_NAME](#), but stores the name as a global.

### DELETE\_GLOBAL(*namei*)

Works as [DELETE\\_NAME](#), but deletes a global name.

### LOAD\_CONST(*consti*)

Pushes `co_consts[consti]` onto the stack.

### LOAD\_NAME(*namei*)

Pushes the value associated with `co_names[namei]` onto the stack. The name is looked up within the locals, then the globals, then the builtins.

## LOAD\_LOCALS

Pushes a reference to the locals dictionary onto the stack. This is used to prepare namespace dictionaries for [LOAD\\_FROM\\_DICT\\_OR\\_DEREF](#) and [LOAD\\_FROM\\_DICT\\_OR\\_GLOBALS](#).

*New in version 3.12.*

## LOAD\_FROM\_DICT\_OR\_GLOBALS(*i*)

Pops a mapping off the stack and looks up the value for `co_names[namei]`. If the name is not found there, looks it up in the globals and then the builtins, similar to [LOAD\\_GLOBAL](#). This is used for loading global variables in [annotation scopes](#) within class bodies.

*New in version 3.12.*

## BUILD\_TUPLE(*count*)

Creates a tuple consuming *count* items from the stack, and pushes the resulting tuple onto the stack.:

```
assert count > 0
STACK, values = STACK[:-count], STACK[-count:]
STACK.append(tuple(values))
```

## BUILD\_LIST(*count*)

Works as [BUILD\\_TUPLE](#), but creates a list.

## BUILD\_SET(*count*)

Works as [BUILD\\_TUPLE](#), but creates a set.

## BUILD\_MAP(*count*)

Pushes a new dictionary object onto the stack. Pops  $2 * \text{count}$  items so that the dictionary holds *count* entries:  
`{..., STACK[-4]: STACK[-3], STACK[-2]: STACK[-1]}`.

*Changed in version 3.5:* The dictionary is created from stack items instead of creating an empty dictionary pre-sized to hold *count* items.

### **BUILD\_CONST\_KEY\_MAP(*count*)**

The version of **BUILD\_MAP** specialized for constant keys. Pops the top element on the stack which contains a tuple of keys, then starting from `STACK[-2]`, pops *count* values to form values in the built dictionary.

*New in version 3.6.*

### **BUILD\_STRING(*count*)**

Concatenates *count* strings from the stack and pushes the resulting string onto the stack.

*New in version 3.6.*

### **LIST\_EXTEND(*i*)**

Implements:

```
seq = STACK.pop()
list.extend(STACK[-i], seq)
```

Used to build lists.

*New in version 3.9.*

### **SET\_UPDATE(*i*)**

Implements:

```
seq = STACK.pop()
set.update(STACK[-i], seq)
```

Used to build sets.

*New in version 3.9.*

### **DICT\_UPDATE(*i*)**

Implements:

```
map = STACK.pop()  
dict.update(STACK[-1], map)
```

Used to build dicts.

*New in version 3.9.*

## DICT\_MERGE(*i*)

Like **DICT\_UPDATE** but raises an exception for duplicate keys.

*New in version 3.9.*

## LOAD\_ATTR(*namei*)

If the low bit of *namei* is not set, this replaces `STACK[-1]` with `getattr(STACK[-1], co_names[namei>>1])`.

If the low bit of *namei* is set, this will attempt to load a method named `co_names[namei>>1]` from the `STACK[-1]` object. `STACK[-1]` is popped. This bytecode distinguishes two cases: if `STACK[-1]` has a method with the correct name, the bytecode pushes the unbound method and `STACK[-1]`. `STACK[-1]` will be used as the first argument (*self*) by **CALL** when calling the unbound method. Otherwise, `NULL` and the object returned by the attribute lookup are pushed.

*Changed in version 3.12:* If the low bit of *namei* is set, then a `NULL` or *self* is pushed to the stack before the attribute or unbound method respectively.

## LOAD\_SUPER\_ATTR(*namei*)

This opcode implements **super()** (e.g. `super().method()` and `super().attr`). It works the same as **LOAD\_ATTR**, except that *namei* is shifted left by 2 bits instead of 1, and instead of expecting a single receiver on the stack, it expects three objects (from top of stack down):

`self` (the first argument to the current method), `cls` (the class within which the current method was defined), and the global `super`.

The low bit of `namei` signals to attempt a method load, as with **LOAD\_ATTR**.

The second-low bit of `namei`, if set, means that this was a two-argument call to **super()** (unset means zero-argument).

*New in version 3.12.*

### COMPARE\_OP(*opname*)

Performs a Boolean operation. The operation name can be found in `cmp_op[opname]`.

### IS\_OP(*invert*)

Performs `is` comparison, or `is not` if `invert` is 1.

*New in version 3.9.*

### CONTAINS\_OP(*invert*)

Performs `in` comparison, or `not in` if `invert` is 1.

*New in version 3.9.*

### IMPORT\_NAME(*namei*)

Imports the module `co_names[namei]`. `STACK[-1]` and `STACK[-2]` are popped and provide the *fromlist* and *level* arguments of **\_\_import\_\_()**. The module object is pushed onto the stack. The current namespace is not affected: for a proper import statement, a subsequent **STORE\_FAST** instruction modifies the namespace.

### IMPORT\_FROM(*namei*)

Loads the attribute `co_names[namei]` from the module found in `STACK[-1]`. The resulting object is pushed onto the stack, to be subsequently stored by a **STORE\_FAST**

instruction.

#### JUMP\_FORWARD(*delta*)

Increments bytecode counter by *delta*.

#### JUMP\_BACKWARD(*delta*)

Decrements bytecode counter by *delta*. Checks for interrupts.

*New in version 3.11.*

#### JUMP\_BACKWARD\_NO\_INTERRUPT(*delta*)

Decrements bytecode counter by *delta*. Does not check for interrupts.

*New in version 3.11.*

#### POP\_JUMP\_IF\_TRUE(*delta*)

If `STACK[-1]` is true, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

*Changed in version 3.11:* The oparg is now a relative delta rather than an absolute target. This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

*Changed in version 3.12:* This is no longer a pseudo-instruction.

#### POP\_JUMP\_IF\_FALSE(*delta*)

If `STACK[-1]` is false, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

*Changed in version 3.11:* The oparg is now a relative delta rather than an absolute target. This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

*Changed in version 3.12:* This is no longer a pseudo-

instruction.

### POP\_JUMP\_IF\_NOT\_NONE(*delta*)

If `STACK[-1]` is not `None`, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

*New in version 3.11.*

*Changed in version 3.12:* This is no longer a pseudo-instruction.

### POP\_JUMP\_IF\_NONE(*delta*)

If `STACK[-1]` is `None`, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

*New in version 3.11.*

*Changed in version 3.12:* This is no longer a pseudo-instruction.

### FOR\_ITER(*delta*)

`STACK[-1]` is an [iterator](#). Call its `__next__()` method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted then the byte code counter is incremented by *delta*.

*Changed in version 3.12:* Up until 3.11 the iterator was popped when it was exhausted.

### LOAD\_GLOBAL(*namei*)

Loads the global named `co_names[namei>>1]` onto the stack.

*Changed in version 3.11:* If the low bit of `namei` is set, then a `NULL` is pushed to the stack before the global variable.

### `LOAD_FAST(var_num)`

Pushes a reference to the local `co_varnames[var_num]` onto the stack.

*Changed in version 3.12:* This opcode is now only used in situations where the local variable is guaranteed to be initialized. It cannot raise `UnboundLocalError`.

### `LOAD_FAST_CHECK(var_num)`

Pushes a reference to the local `co_varnames[var_num]` onto the stack, raising an `UnboundLocalError` if the local variable has not been initialized.

*New in version 3.12.*

### `LOAD_FAST_AND_CLEAR(var_num)`

Pushes a reference to the local `co_varnames[var_num]` onto the stack (or pushes `NULL` onto the stack if the local variable has not been initialized) and sets `co_varnames[var_num]` to `NULL`.

*New in version 3.12.*

### `STORE_FAST(var_num)`

Stores `STACK.pop()` into the local `co_varnames[var_num]`.

### `DELETE_FAST(var_num)`

Deletes local `co_varnames[var_num]`.

### `MAKE_CELL(i)`

Creates a new cell in slot `i`. If that slot is nonempty then that value is stored into the new cell.

*New in version 3.11.*

## LOAD\_CLOSURE(*i*)

Pushes a reference to the cell contained in slot *i* of the “fast locals” storage. The name of the variable is `co_fastlocalnames[i]`.

Note that `LOAD_CLOSURE` is effectively an alias for `LOAD_FAST`. It exists to keep bytecode a little more readable.

*Changed in version 3.11:* *i* is no longer offset by the length of `co_varnames`.

## LOAD\_DEREF(*i*)

Loads the cell contained in slot *i* of the “fast locals” storage. Pushes a reference to the object the cell contains on the stack.

*Changed in version 3.11:* *i* is no longer offset by the length of `co_varnames`.

## LOAD\_FROM\_DICT\_OR\_DEREF(*i*)

Pops a mapping off the stack and looks up the name associated with slot *i* of the “fast locals” storage in this mapping. If the name is not found there, loads it from the cell contained in slot *i*, similar to `LOAD_DEREF`. This is used for loading free variables in class bodies (which previously used `LOAD_CLASSDEREF`) and in [annotation scopes](#) within class bodies.

*New in version 3.12.*

## STORE\_DEREF(*i*)

Stores `STACK.pop()` into the cell contained in slot *i* of the “fast locals” storage.

*Changed in version 3.11:* *i* is no longer offset by the length of `co_varnames`.

## DELETE\_DEREF(*i*)

Empties the cell contained in slot *i* of the “fast locals” storage. Used by the `del` statement.

*New in version 3.2.*

*Changed in version 3.11:* *i* is no longer offset by the length of `co_varnames`.

## COPY\_FREE\_VARS(*n*)

Copies the *n* free variables from the closure into the frame. Removes the need for special code on the caller’s side when calling closures.

*New in version 3.11.*

## RAISE\_VARARGS(*argc*)

Raises an exception using one of the 3 forms of the `raise` statement, depending on the value of *argc*:

- 0: `raise` (re-raise previous exception)
- 1: `raise STACK[-1]` (raise exception instance or type at `STACK[-1]`)
- 2: `raise STACK[-2] from STACK[-1]` (raise exception instance or type at `STACK[-2]` with `__cause__` set to `STACK[-1]`)

## CALL(*argc*)

Calls a callable object with the number of arguments specified by *argc*, including the named arguments specified by the preceding `KW_NAMES`, if any. On the stack are (in ascending order), either:

- NULL
- The callable
- The positional arguments
- The named arguments

or:

- The callable
- `self`
- The remaining positional arguments
- The named arguments

`argc` is the total of the positional and named arguments, excluding `self` when a `NULL` is not present.

`CALL` pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

*New in version 3.11.*

### `CALL_FUNCTION_EX(flags)`

Calls a callable object with variable set of positional and keyword arguments. If the lowest bit of `flags` is set, the top of the stack contains a mapping object containing additional keyword arguments. Before the callable is called, the mapping object and iterable object are each “unpacked” and their contents passed in as keyword and positional arguments respectively. `CALL_FUNCTION_EX` pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

*New in version 3.6.*

### `PUSH_NULL`

Pushes a `NULL` to the stack. Used in the call sequence to match the `NULL` pushed by `LOAD_METHOD` for non-method calls.

*New in version 3.11.*

### `KW_NAMES(consti)`

Prefixes `CALL`. Stores a reference to `co_consts[consti]` into an internal variable for use by `CALL`. `co_consts[consti]` must be a tuple of strings.

*New in version 3.11.*

## MAKE\_FUNCTION(*flags*)

Pushes a new function object on the stack. From bottom to top, the consumed stack must consist of values if the argument carries a specified flag value

- 0x01 a tuple of default values for positional-only and positional-or-keyword parameters in positional order
- 0x02 a dictionary of keyword-only parameters' default values
- 0x04 a tuple of strings containing parameters' annotations
- 0x08 a tuple containing cells for free variables, making a closure
- the code associated with the function (at `STACK[-1]`)

*Changed in version 3.10:* Flag value 0x04 is a tuple of strings instead of dictionary

*Changed in version 3.11:* Qualified name at `STACK[-1]` was removed.

## BUILD\_SLICE(*argc*)

Pushes a slice object on the stack. *argc* must be 2 or 3. If it is 2, implements:

```
end = STACK.pop()
start = STACK.pop()
STACK.append(slice(start, stop))
```

if it is 3, implements:

```
step = STACK.pop()
end = STACK.pop()
start = STACK.pop()
STACK.append(slice(start, end, step))
```

See the [`slice\(\)`](#) built-in function for more information.

## EXTENDED\_ARG(*ext*)

Prefixes any opcode which has an argument too big to fit into the default one byte. *ext* holds an additional byte which act as higher bits in the argument. For each opcode, at most three prefixal EXTENDED\_ARG are allowed, forming an argument from two-byte to four-byte.

## FORMAT\_VALUE(*flags*)

Used for implementing formatted literal strings (f-strings). Pops an optional *fmt\_spec* from the stack, then a required *value*. *flags* is interpreted as follows:

- (flags & 0x03) == 0x00: *value* is formatted as-is.
- (flags & 0x03) == 0x01: call `str()` on *value* before formatting it.
- (flags & 0x03) == 0x02: call `repr()` on *value* before formatting it.
- (flags & 0x03) == 0x03: call `ascii()` on *value* before formatting it.
- (flags & 0x04) == 0x04: pop *fmt\_spec* from the stack and use it, else use an empty *fmt\_spec*.

Formatting is performed using `PyObject_Format()`. The result is pushed on the stack.

*New in version 3.6.*

## MATCH\_CLASS(*count*)

STACK[-1] is a tuple of keyword attribute names, STACK[-2] is the class being matched against, and STACK[-3] is the match subject. *count* is the number of positional sub-patterns.

Pop STACK[-1], STACK[-2], and STACK[-3]. If STACK[-3] is an instance of STACK[-2] and has the positional and keyword attributes required by *count* and STACK[-1], push a tuple of extracted attributes. Otherwise, push None.

*New in version 3.10.*

*Changed in version 3.11:* Previously, this instruction also pushed a boolean value indicating success (`True`) or failure (`False`).

## RESUME(*where*)

A no-op. Performs internal tracing, debugging and optimization checks.

The `where` operand marks where the `RESUME` occurs:

- 0 The start of a function, which is neither a generator, coroutine nor an async generator
- 1 After a `yield` expression
- 2 After a `yield from` expression
- 3 After an `await` expression

*New in version 3.11.*

## RETURN\_GENERATOR

Create a generator, coroutine, or async generator from the current frame. Used as first opcode of in code object for the above mentioned callables. Clear the current frame and return the newly created generator.

*New in version 3.11.*

## SEND(*delta*)

Equivalent to `STACK[-1] = STACK[-2].send(STACK[-1])`. Used in `yield from` and `await` statements.

If the call raises `StopIteration`, pop both items, push the exception's `value` attribute, and increment the bytecode counter by *delta*.

*New in version 3.11.*

## HAVE\_ARGUMENT

This is not really an opcode. It identifies the dividing line between opcodes in the range [0,255] which don't use their argument and those that do (< HAVE\_ARGUMENT and >= HAVE\_ARGUMENT, respectively).

If your application uses pseudo instructions, use the [hasarg](#) collection instead.

*Changed in version 3.6:* Now every instruction has an argument, but opcodes < HAVE\_ARGUMENT ignore it. Before, only opcodes >= HAVE\_ARGUMENT had an argument.

*Changed in version 3.12:* Pseudo instructions were added to the [dis](#) module, and for them it is not true that comparison with HAVE\_ARGUMENT indicates whether they use their arg.

## CALL\_INTRINSIC\_1

Calls an intrinsic function with one argument. Passes STACK[-1] as the argument and sets STACK[-1] to the result. Used to implement functionality that is necessary but not performance critical.

The operand determines which intrinsic function is called:

### Description

---

NotranNIC\_1\_INVALID

---

Prints the argument to standard out. Used in the REPL.

---

Performs `import` for the named module.

---

Extracts the return value from a `try` iteration exception.

---

Wraps an `async` generator value

---

Performs the unary `+` operation

---

Converts a list to a tuple

---

Creates a [typing.TypeVar](#)

---

Creates a [typing.ParamSpec](#)

---

Creates a [typing.TypeAlias](#)

---

Returns [typing.Generic](#) subscripted with the argument

---

Creates a [typing.TypeAlias](#); used in the [type](#) statement. The argument is a tuple of the type alias's name, type parameters, and value.

---

*New in version 3.12.*

## CALL\_INTRINSIC\_2

Calls an intrinsic function with two arguments. Passes `STACK[-2]`, `STACK[-1]` as the arguments and sets `STACK[-1]` to the result. Used to implement functionality that is necessary but not performance critical.

The operand determines which intrinsic function is called:

### Description

---

Not raised `CALL_INTRINSIC_2_INVALID`

---

Calculates the `try-raise` from a `try-except*`.

---

Creates `CTypeVar` with `unbound`.

---

Creates `CTypeVar` with constraints.

---

Sets the `SICL_SET_FUNCTION` attribute of a function.

---

*New in version 3.12.*

## Pseudo-instructions

These opcodes do not appear in Python bytecode. They are used by the compiler but are replaced by real opcodes or removed before bytecode is generated.

### SETUP\_FINALLY(*target*)

Set up an exception handler for the following code block. If an exception occurs, the value stack level is restored to its current state and control is transferred to the exception handler at `target`.

### SETUP\_CLEANUP(*target*)

Like `SETUP_FINALLY`, but in case of an exception also pushes the last instruction (`lasti`) to the stack so that `RERAISE` can restore it. If an exception occurs, the value stack level and the last instruction on the frame are restored to their current state, and control is transferred to the exception handler at `target`.

## SETUP\_WITH(*target*)

Like `SETUP_CLEANUP`, but in case of an exception one more item is popped from the stack before control is transferred to the exception handler at `target`.

This variant is used in `with` and `async with` constructs, which push the return value of the context manager's `__enter__()` or `__aenter__()` to the stack.

## POP\_BLOCK

Marks the end of the code block associated with the last `SETUP_FINALLY`, `SETUP_CLEANUP` or `SETUP_WITH`.

## JUMP

## JUMP\_NO\_INTERRUPT

Undirected relative jump instructions which are replaced by their directed (forward/backward) counterparts by the assembler.

## LOAD\_METHOD

Optimized unbound method lookup. Emitted as a `LOAD_ATTR` opcode with a flag set in the arg.

# Opcode collections

These collections are provided for automatic introspection of bytecode instructions:

*Changed in version 3.12:* The collections now contain pseudo instructions as well. These are opcodes with values `>= MIN_PSEUDO_OPCODE`.

### dis.opname

Sequence of operation names, indexable using the bytecode.

### dis.opmap

Dictionary mapping operation names to bytecodes.

`dis.cmp_op`

Sequence of all compare operation names.

`dis.hasarg`

Sequence of bytecodes that use their argument.

*New in version 3.12.*

`dis.hasconst`

Sequence of bytecodes that access a constant.

`dis.hasfree`

Sequence of bytecodes that access a free variable. ‘free’ in this context refers to names in the current scope that are referenced by inner scopes or names in outer scopes that are referenced from this scope. It does *not* include references to global or builtin scopes.

`dis.hasname`

Sequence of bytecodes that access an attribute by name.

`dis.hasjrel`

Sequence of bytecodes that have a relative jump target.

`dis.hasjabs`

Sequence of bytecodes that have an absolute jump target.

`dis.haslocal`

Sequence of bytecodes that access a local variable.

`dis.hascompare`

Sequence of bytecodes of Boolean operations.

`dis.hasexc`

Sequence of bytecodes that set an exception handler.

*New in version 3.12.*

# `pickletools` — Tools for pickle developers

**Source code:** [Lib/pickletools.py](https://github.com/python/cpython/tree/3.12/Lib/pickletools.py) [https://github.com/python/cpython/tree/3.12/Lib/pickletools.py]

---

This module contains various constants relating to the intimate details of the `pickle` module, some lengthy comments about the implementation, and a few useful functions for analyzing pickled data. The contents of this module are useful for Python core developers who are working on the `pickle`; ordinary users of the `pickle` module probably won't find the `pickletools` module relevant.

## Command line usage

*New in version 3.2.*

When invoked from the command line, `python -m pickletools` will disassemble the contents of one or more pickle files. Note that if you want to see the Python object stored in the pickle rather than the details of pickle format, you may want to use `-m pickle` instead. However, when the pickle file that you want to examine comes from an untrusted source, `-m pickletools` is a safer option because it does not execute pickle bytecode.

For example, with a tuple `(1, 2)` pickled in file `x.pickle`:

```
$ python -m pickle x.pickle
(1, 2)
```

```
$ python -m pickletools x.pickle
0: \x80 PROTO      3
2: K      BININT1   1
```

```

4: K      BININT1      2
6: \x86  TUPLE2
7: q      BININPUT     0
9: .      STOP

```

highest protocol among opcodes = 2

## Command line options

**-a, --annotate**

Annotate each line with a short opcode description.

**-o, --output = <file>**

Name of a file where the output should be written.

**-l, --indentlevel = <num>**

The number of blanks by which to indent a new MARK level.

**-m, --memo**

When multiple objects are disassembled, preserve memo between disassemblies.

**-p, --preamble = <preamble>**

When more than one pickle file are specified, print given preamble before each disassembly.

## Programmatic Interface

`pickletools.dis(pickle, out=None, memo=None, indentlevel=4, annotate=0)`

Outputs a symbolic disassembly of the pickle to the file-like object *out*, defaulting to `sys.stdout`. *pickle* can be a string or a file-like object. *memo* can be a Python dictionary that will be used as the pickle's memo; it can be used to perform disassemblies across multiple pickles created by the same pickler. Successive levels, indicated by MARK opcodes in the stream, are indented by *indentlevel* spaces. If a nonzero value is given to *annotate*, each opcode in the output is annotated

with a short description. The value of *annotate* is used as a hint for the column where annotation should start.

*New in version 3.2:* The *annotate* argument.

`pickletools.genops(pickle)`

Provides an [iterator](#) over all of the opcodes in a pickle, returning a sequence of (*opcode*, *arg*, *pos*) triples. *opcode* is an instance of an **OpcodeInfo** class; *arg* is the decoded value, as a Python object, of the opcode's argument; *pos* is the position at which this opcode is located. *pickle* can be a string or a file-like object.

`pickletools.optimize(picklestring)`

Returns a new equivalent pickle string after eliminating unused `PUT` opcodes. The optimized pickle is shorter, takes less transmission time, requires less storage space, and unpickles more efficiently.

# MS Windows Specific Services

This chapter describes modules that are only available on MS Windows platforms.

- **msvcrt** — Useful routines from the MS VC++ runtime
  - File Operations
  - Console I/O
  - Other Functions
- **winreg** — Windows registry access
  - Functions
  - Constants
    - HKEY\_\* Constants
    - Access Rights
    - 64-bit Specific
    - Value Types
  - Registry Handle Objects
- **winsound** — Sound-playing interface for Windows

# msvcrt — Useful routines from the MS VC++ runtime

---

These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the `getpass` module uses this in the implementation of the `getpass()` function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used where ever possible.

*Changed in version 3.3:* Operations in this module now raise `OSError` where `IOError` was raised.

## File Operations

`msvcrt.locking(fd, mode, nbytes)`

Lock part of a file based on file descriptor *fd* from the C runtime. Raises `OSError` on failure. The locked region of the file extends from the current file position for *nbytes* bytes, and may continue beyond the end of the file. *mode* must be one of the `LK_*` constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged; they must be unlocked individually.

Raises an `auditing event` `msvcrt.locking` with arguments *fd*, *mode*, *nbytes*.

`msvcrt.LK_LOCK`

`msvcrt.LK_RLCK`

Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, `OSError` is raised.

`msvcrt.LK_NBLCK`

`msvcrt.LK_NBRLOCK`

Locks the specified bytes. If the bytes cannot be locked, `OSError` is raised.

`msvcrt.LK_UNLCK`

Unlocks the specified bytes, which must have been previously locked.

`msvcrt.setmode(fd, flags)`

Set the line-end translation mode for the file descriptor *fd*. To set it to text mode, *flags* should be `os.O_TEXT`; for binary, it should be `os.O_BINARY`.

`msvcrt.open_oshandle(handle, flags)`

Create a C runtime file descriptor from the file handle *handle*. The *flags* parameter should be a bitwise OR of `os.O_APPEND`, `os.O_RDONLY`, and `os.O_TEXT`. The returned file descriptor may be used as a parameter to `os.fdopen()` to create a file object.

Raises an `auditing event` `msvcrt.open_oshandle` with arguments *handle*, *flags*.

`msvcrt.get_oshandle(fd)`

Return the file handle for the file descriptor *fd*. Raises `OSError` if *fd* is not recognized.

Raises an `auditing event` `msvcrt.get_oshandle` with argument *fd*.

# Console I/O

`msvcrt.kbhit()`

Return `True` if a keypress is waiting to be read.

`msvcrt.getch()`

Read a keypress and return the resulting character as a byte string. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for `Enter` to be pressed. If the pressed key was a special function key, this will return `'\000'` or `'\xe0'`; the next call will return the keycode. The `Control-C` keypress cannot be read with this function.

`msvcrt.getwch()`

Wide char variant of `getch()`, returning a Unicode value.

`msvcrt.getche()`

Similar to `getch()`, but the keypress will be echoed if it represents a printable character.

`msvcrt.getwche()`

Wide char variant of `getche()`, returning a Unicode value.

`msvcrt.putch(char)`

Print the byte string *char* to the console without buffering.

`msvcrt.putwch(unicode_char)`

Wide char variant of `putch()`, accepting a Unicode value.

`msvcrt.ungetch(char)`

Cause the byte string *char* to be “pushed back” into the console buffer; it will be the next character read by `getch()` or `getche()`.

`msvcrt.ungetwch(unicode_char)`

Wide char variant of `ungetch()`, accepting a Unicode value.

## Other Functions

`msvcrt.heapmin()`

Force the `malloc()` heap to clean itself up and return unused blocks to the operating system. On failure, this raises `OSError`.

# winreg — Windows registry access

---

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a [handle object](#) is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

*Changed in version 3.3:* Several functions in this module used to raise a [WindowsError](#), which is now an alias of [OSError](#).

## Functions

This module offers the following functions:

`winreg.CloseKey(hkey)`

Closes a previously opened registry key. The *hkey* argument specifies a previously opened key.

### Note

If *hkey* is not closed using this method (or via [hkey.Close\(\)](#)), it is closed when the *hkey* object is destroyed by Python.

`winreg.ConnectRegistry(computer_name, key)`

Establishes a connection to a predefined registry handle on another computer, and returns a [handle object](#).

*computer\_name* is the name of the remote computer, of the form `r"\\computername"`. If `None`, the local computer is used.

key is the predefined handle to connect to.

The return value is the handle of the opened key. If the function fails, an **OSError** exception is raised.

Raises an **auditing event** `winreg.ConnectRegistry` with arguments `computer_name`, `key`.

*Changed in version 3.3:* See [above](#).

`winreg.CreateKey(key, sub_key)`

Creates or opens the specified key, returning a **handle object**.

key is an already open key, or one of the predefined **HKEY\_\* constants**.

sub\_key is a string that names the key this method opens or creates.

If key is one of the predefined keys, sub\_key may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an **OSError** exception is raised.

Raises an **auditing event** `winreg.CreateKey` with arguments `key`, `sub_key`, `access`.

Raises an **auditing event** `winreg.OpenKey/result` with argument `key`.

*Changed in version 3.3:* See [above](#).

`winreg.CreateKeyEx(key, sub_key, reserved=0, access=KEY_WRITE)`

Creates or opens the specified key, returning a **handle object**.

key is an already open key, or one of the predefined **HKEY\_\* constants**.

*sub\_key* is a string that names the key this method opens or creates.

*reserved* is a reserved integer, and must be zero. The default is zero.

*access* is an integer that specifies an access mask that describes the desired security access for the key. Default is [KEY\\_WRITE](#). See [Access Rights](#) for other allowed values.

If *key* is one of the predefined keys, *sub\_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an [OSError](#) exception is raised.

Raises an [auditing event](#) `winreg.CreateKey` with arguments `key`, `sub_key`, `access`.

Raises an [auditing event](#) `winreg.OpenKey/result` with argument `key`.

*New in version 3.2.*

*Changed in version 3.3:* See [above](#).

`winreg.DeleteKey(key, sub_key)`

Deletes the specified key.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

*sub\_key* is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its

values, is removed. If the method fails, an **OSError** exception is raised.

Raises an **auditing event** `winreg.DeleteKey` with arguments `key`, `sub_key`, `access`.

*Changed in version 3.3:* See [above](#).

```
winreg.DeleteKeyEx(key, sub_key, access=KEY_WOW64_64KEY,  
reserved=0)
```

Deletes the specified key.

`key` is an already open key, or one of the predefined **HKEY\_\* constants**.

`sub_key` is a string that must be a subkey of the key identified by the `key` parameter. This value must not be `None`, and the key may not have subkeys.

`reserved` is a reserved integer, and must be zero. The default is zero.

`access` is an integer that specifies an access mask that describes the desired security access for the key. Default is **KEY\_WOW64\_64KEY**. On 32-bit Windows, the WOW64 constants are ignored. See [Access Rights](#) for other allowed values.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an **OSError** exception is raised.

On unsupported Windows versions, **NotImplementedError** is raised.

Raises an **auditing event** `winreg.DeleteKey` with arguments `key`, `sub_key`, `access`.

*New in version 3.2.*

*Changed in version 3.3: See [above](#).*

`winreg.DeleteValue(key, value)`

Removes a named value from a registry key.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

*value* is a string that identifies the value to remove.

Raises an [auditing event](#) `winreg.DeleteValue` with arguments `key`, `value`.

`winreg.EnumKey(key, index)`

Enumerates subkeys of an open registry key, returning a string.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

*index* is an integer that identifies the index of the key to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly until an [OSError](#) exception is raised, indicating, no more values are available.

Raises an [auditing event](#) `winreg.EnumKey` with arguments `key`, `index`.

*Changed in version 3.3: See [above](#).*

`winreg.EnumValue(key, index)`

Enumerates values of an open registry key, returning a tuple.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

*index* is an integer that identifies the index of the value to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly, until an [OSError](#) exception is raised, indicating no more values.

The result is a tuple of 3 items:

#### **Indexing**

---

A string that identifies the value name

---

An object that holds the value data, and whose type depends on the underlying registry type

---

An integer that identifies the type of the value data (see table in docs for [SetValueEx\(\)](#))

---

Raises an [auditing event](#) `winreg.EnumValue` with arguments `key`, `index`.

*Changed in version 3.3:* See [above](#).

### `winreg.ExpandEnvironmentStrings(str)`

Expands environment variable placeholders `%NAME%` in strings like [REG\\_EXPAND\\_SZ](#):

```
>>> ExpandEnvironmentStrings('%windir%')
'C:\\Windows'
```

Raises an [auditing event](#)

`winreg.ExpandEnvironmentStrings` with argument `str`.

### `winreg.FlushKey(key)`

Writes all the attributes of a key to the registry.

`key` is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

It is not necessary to call [FlushKey\(\)](#) to change a key. Registry changes are flushed to disk by the registry using its lazy flusher. Registry changes are also flushed to disk at system shutdown. Unlike [CloseKey\(\)](#), the [FlushKey\(\)](#) method returns only when all the data has been written to the

registry. An application should only call **FlushKey()** if it requires absolute certainty that registry changes are on disk.

### Note

If you don't know whether a **FlushKey()** call is required, it probably isn't.

**winreg.LoadKey(*key*, *sub\_key*, *file\_name*)**

Creates a subkey under the specified key and stores registration information from a specified file into that subkey.

*key* is a handle returned by **ConnectRegistry()** or one of the constants **HKEY\_USERS** or **HKEY\_LOCAL\_MACHINE**.

*sub\_key* is a string that identifies the subkey to load.

*file\_name* is the name of the file to load registry data from. This file must have been created with the **SaveKey()** function. Under the file allocation table (FAT) file system, the filename may not have an extension.

A call to **LoadKey()** fails if the calling process does not have the **SE\_RESTORE\_PRIVILEGE** privilege. Note that privileges are different from permissions – see the [RegLoadKey documentation](https://msdn.microsoft.com/en-us/library/ms724889%28v=VS.85%29.aspx) [https://msdn.microsoft.com/en-us/library/ms724889%28v=VS.85%29.aspx] for more details.

If *key* is a handle returned by **ConnectRegistry()**, then the path specified in *file\_name* is relative to the remote computer.

Raises an [auditing event](#) winreg.LoadKey with arguments *key*, *sub\_key*, *file\_name*.

**winreg.OpenKey(*key*, *sub\_key*, *reserved*=0, *access*=KEY\_READ)**

**winreg.OpenKeyEx(*key*, *sub\_key*, *reserved*=0, *access*=KEY\_READ)**

Opens the specified key, returning a [handle object](#).

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

*sub\_key* is a string that identifies the sub\_key to open.

*reserved* is a reserved integer, and must be zero. The default is zero.

*access* is an integer that specifies an access mask that describes the desired security access for the key. Default is [KEY\\_READ](#). See [Access Rights](#) for other allowed values.

The result is a new handle to the specified key.

If the function fails, [OSError](#) is raised.

Raises an [auditing event](#) `winreg.OpenKey` with arguments `key`, `sub_key`, `access`.

Raises an [auditing event](#) `winreg.OpenKey/result` with argument `key`.

*Changed in version 3.2:* Allow the use of named arguments.

*Changed in version 3.3:* See [above](#).

## `winreg.QueryInfoKey(key)`

Returns information about a key, as a tuple.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

The result is a tuple of 3 items:

### **~~Meaning~~**

---

An integer giving the number of sub keys this key has.

---

An integer giving the number of values this key has.

---

An integer giving when the key was last modified (if available) as 100's of nanoseconds since Jan 1, 1601.

---

Raises an [auditing event](#) `winreg.QueryInfoKey` with argument `key`.

`winreg.QueryValue(key, sub_key)`

Retrieves the unnamed value for a key, as a string.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

*sub\_key* is a string that holds the name of the subkey with which the value is associated. If this parameter is `None` or empty, the function retrieves the value set by the [SetValue\(\)](#) method for the key identified by *key*.

Values in the registry have name, type, and data components. This method retrieves the data for a key's first value that has a `NULL` name. But the underlying API call doesn't return the type, so always use [QueryValueEx\(\)](#) if possible.

Raises an [auditing event](#) `winreg.QueryValue` with arguments `key`, `sub_key`, `value_name`.

`winreg.QueryValueEx(key, value_name)`

Retrieves the type and data for a specified value name associated with an open registry key.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

*value\_name* is a string indicating the value to query.

The result is a tuple of 2 items:

<b>Indexing</b>
The value of the registry item.
An integer giving the registry type for this value (see table in docs for <a href="#">SetValueEx()</a> )

Raises an [auditing event](#) `winreg.QueryValue` with arguments `key`, `sub_key`, `value_name`.

`winreg.SaveKey(key, file_name)`

Saves the specified key, and all its subkeys to the specified

file.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

*file\_name* is the name of the file to save registry data to. This file cannot already exist. If this filename includes an extension, it cannot be used on file allocation table (FAT) file systems by the [LoadKey \(\)](#) method.

If *key* represents a key on a remote computer, the path described by *file\_name* is relative to the remote computer. The caller of this method must possess the **SeBackupPrivilege** security privilege. Note that privileges are different than permissions – see the [Conflicts Between User Rights and Permissions documentation](#) [<https://msdn.microsoft.com/en-us/library/ms724878%28v=VS.85%29.aspx>] for more details.

This function passes `NULL` for *security\_attributes* to the API.

Raises an [auditing event](#) `winreg.SaveKey` with arguments *key*, *file\_name*.

`winreg.SetValue(key, sub_key, type, value)`

Associates a value with a specified key.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

*sub\_key* is a string that names the subkey with which the value is associated.

*type* is an integer that specifies the type of the data. Currently this must be [REG\\_SZ](#), meaning only strings are supported. Use the [SetValueEx \(\)](#) function for support for other data types.

*value* is a string that specifies the new value.

If the key specified by the *sub\_key* parameter does not exist, the `SetValue` function creates it.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

The key identified by the *key* parameter must have been opened with **KEY\_SET\_VALUE** access.

Raises an **auditing event** `winreg.SetValue` with arguments *key*, *sub\_key*, *type*, *value*.

`winreg.SetValueEx(key, value_name, reserved, type, value)`

Stores data in the value field of an open registry key.

*key* is an already open key, or one of the predefined **HKEY\_\* constants**.

*value\_name* is a string that names the subkey with which the value is associated.

*reserved* can be anything – zero is always passed to the API.

*type* is an integer that specifies the type of the data. See **Value Types** for the available types.

*value* is a string that specifies the new value.

This method can also set additional value and type information for the specified key. The key identified by the *key* parameter must have been opened with **KEY\_SET\_VALUE** access.

To open the key, use the **CreateKey()** or **OpenKey()** methods.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

Raises an **auditing event** `winreg.SetValue` with arguments

key, sub\_key, type, value.

### winreg.DisableReflectionKey(key)

Disables registry reflection for 32-bit processes running on a 64-bit operating system.

key is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

Will generally raise [NotImplementedError](#) if executed on a 32-bit operating system.

If the key is not on the reflection list, the function succeeds but has no effect. Disabling reflection for a key does not affect reflection of any subkeys.

Raises an [auditing event](#) winreg.DisableReflectionKey with argument key.

### winreg.EnableReflectionKey(key)

Restores registry reflection for the specified disabled key.

key is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

Will generally raise [NotImplementedError](#) if executed on a 32-bit operating system.

Restoring reflection for a key does not affect reflection of any subkeys.

Raises an [auditing event](#) winreg.EnableReflectionKey with argument key.

### winreg.QueryReflectionKey(key)

Determines the reflection state for the specified key.

key is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

Returns `True` if reflection is disabled.

Will generally raise `NotImplementedError` if executed on a 32-bit operating system.

Raises an `auditing event` `winreg.QueryReflectionKey` with argument `key`.

## Constants

The following constants are defined for use in many `winreg` functions.

### **HKEY\_\* Constants**

`winreg.HKEY_CLASSES_ROOT`

Registry entries subordinate to this key define types (or classes) of documents and the properties associated with those types. Shell and COM applications use the information stored under this key.

`winreg.HKEY_CURRENT_USER`

Registry entries subordinate to this key define the preferences of the current user. These preferences include the settings of environment variables, data about program groups, colors, printers, network connections, and application preferences.

`winreg.HKEY_LOCAL_MACHINE`

Registry entries subordinate to this key define the physical state of the computer, including data about the bus type, system memory, and installed hardware and software.

`winreg.HKEY_USERS`

Registry entries subordinate to this key define the default user configuration for new users on the local computer and the user configuration for the current user.

`winreg.HKEY_PERFORMANCE_DATA`

Registry entries subordinate to this key allow you to access performance data. The data is not actually stored in the registry; the registry functions cause the system to collect the data from its source.

winreg.HKEY\_CURRENT\_CONFIG

Contains information about the current hardware profile of the local computer system.

winreg.HKEY\_DYN\_DATA

This key is not used in versions of Windows after 98.

## Access Rights

For more information, see [Registry Key Security and Access](https://msdn.microsoft.com/en-us/library/ms724878%28v=VS.85%29.aspx) [https://msdn.microsoft.com/en-us/library/ms724878%28v=VS.85%29.aspx].

winreg.KEY\_ALL\_ACCESS

Combines the STANDARD\_RIGHTS\_REQUIRED, [KEY\\_QUERY\\_VALUE](#), [KEY\\_SET\\_VALUE](#), [KEY\\_CREATE\\_SUB\\_KEY](#), [KEY\\_ENUMERATE\\_SUB\\_KEYS](#), [KEY\\_NOTIFY](#), and [KEY\\_CREATE\\_LINK](#) access rights.

winreg.KEY\_WRITE

Combines the STANDARD\_RIGHTS\_WRITE, [KEY\\_SET\\_VALUE](#), and [KEY\\_CREATE\\_SUB\\_KEY](#) access rights.

winreg.KEY\_READ

Combines the STANDARD\_RIGHTS\_READ, [KEY\\_QUERY\\_VALUE](#), [KEY\\_ENUMERATE\\_SUB\\_KEYS](#), and [KEY\\_NOTIFY](#) values.

winreg.KEY\_EXECUTE

Equivalent to [KEY\\_READ](#).

winreg.KEY\_QUERY\_VALUE

Required to query the values of a registry key.

winreg.KEY\_SET\_VALUE

Required to create, delete, or set a registry value.

winreg.KEY\_CREATE\_SUB\_KEY

Required to create a subkey of a registry key.

winreg.KEY\_ENUMERATE\_SUB\_KEYS

Required to enumerate the subkeys of a registry key.

winreg.KEY\_NOTIFY

Required to request change notifications for a registry key or for subkeys of a registry key.

winreg.KEY\_CREATE\_LINK

Reserved for system use.

## 64-bit Specific

For more information, see [Accessing an Alternate Registry View](https://msdn.microsoft.com/en-us/library/aa384129(v=VS.85).aspx)

[[https://msdn.microsoft.com/en-us/library/aa384129\(v=VS.85\).aspx](https://msdn.microsoft.com/en-us/library/aa384129(v=VS.85).aspx)].

winreg.KEY\_WOW64\_64KEY

Indicates that an application on 64-bit Windows should operate on the 64-bit registry view. On 32-bit Windows, this constant is ignored.

winreg.KEY\_WOW64\_32KEY

Indicates that an application on 64-bit Windows should operate on the 32-bit registry view. On 32-bit Windows, this constant is ignored.

## Value Types

For more information, see [Registry Value Types](https://msdn.microsoft.com/en-us/library/ms724884%28v=VS.85%29.aspx) [<https://msdn.microsoft.com/en-us/library/ms724884%28v=VS.85%29.aspx>].

winreg.REG\_BINARY

Binary data in any form.

winreg.REG\_DWORD

32-bit number.

winreg.REG\_DWORD\_LITTLE\_ENDIAN

A 32-bit number in little-endian format. Equivalent to [REG\\_DWORD](#).

winreg.REG\_DWORD\_BIG\_ENDIAN

A 32-bit number in big-endian format.

winreg.REG\_EXPAND\_SZ

Null-terminated string containing references to environment variables (%PATH%).

winreg.REG\_LINK

A Unicode symbolic link.

winreg.REG\_MULTI\_SZ

A sequence of null-terminated strings, terminated by two null characters. (Python handles this termination automatically.)

winreg.REG\_NONE

No defined value type.

winreg.REG\_QWORD

A 64-bit number.

*New in version 3.6.*

winreg.REG\_QWORD\_LITTLE\_ENDIAN

A 64-bit number in little-endian format. Equivalent to [REG\\_QWORD](#).

*New in version 3.6.*

winreg.REG\_RESOURCE\_LIST

A device-driver resource list.

winreg.REG\_FULL\_RESOURCE\_DESCRIPTOR

A hardware setting.

winreg.REG\_RESOURCE\_REQUIREMENTS\_LIST

A hardware resource list.

winreg.REG\_SZ

A null-terminated string.

## Registry Handle Objects

This object wraps a Windows HKEY object, automatically closing it when the object is destroyed. To guarantee cleanup, you can call either the `Close()` method on the object, or the `CloseKey()` function.

All registry functions in this module return one of these objects.

All registry functions in this module which accept a handle object also accept an integer, however, use of the handle object is encouraged.

Handle objects provide semantics for `__bool__()` – thus

```
if handle:
    print("Yes")
```

will print `Yes` if the handle is currently valid (has not been closed or detached).

The object also support comparison semantics, so handle objects will compare true if they both reference the same underlying Windows handle value.

Handle objects can be converted to an integer (e.g., using the builtin `int()` function), in which case the underlying Windows handle

value is returned. You can also use the `Detach()` method to return the integer handle, and also disconnect the Windows handle from the handle object.

### `PyHKEY.Close()`

Closes the underlying Windows handle.

If the handle is already closed, no error is raised.

### `PyHKEY.Detach()`

Detaches the Windows handle from the handle object.

The result is an integer that holds the value of the handle before it is detached. If the handle is already detached or closed, this will return zero.

After calling this function, the handle is effectively invalidated, but the handle is not closed. You would call this function when you need the underlying Win32 handle to exist beyond the lifetime of the handle object.

Raises an [auditing event](#) `winreg.PyHKEY.Detach` with argument `key`.

### `PyHKEY.__enter__()`

### `PyHKEY.__exit__(*exc_info)`

The HKEY object implements `__enter__()` and `__exit__()` and thus supports the context protocol for the `with` statement:

```
with OpenKey(HKEY_LOCAL_MACHINE, "foo") as key:
    ... # work with key
```

will automatically close `key` when control leaves the `with` block.

# winsound — Sound-playing interface for Windows

---

The **winsound** module provides access to the basic sound-playing machinery provided by Windows platforms. It includes functions and several constants.

`winsound.Beep(frequency, duration)`

Beep the PC's speaker. The *frequency* parameter specifies frequency, in hertz, of the sound, and must be in the range 37 through 32,767. The *duration* parameter specifies the number of milliseconds the sound should last. If the system is not able to beep the speaker, **RuntimeError** is raised.

`winsound.PlaySound(sound, flags)`

Call the underlying **PlaySound()** function from the Platform API. The *sound* parameter may be a filename, a system sound alias, audio data as a **bytes-like object**, or `None`. Its interpretation depends on the value of *flags*, which can be a bitwise ORed combination of the constants described below. If the *sound* parameter is `None`, any currently playing waveform sound is stopped. If the system indicates an error, **RuntimeError** is raised.

`winsound.MessageBeep(type = MB_OK)`

Call the underlying **MessageBeep()** function from the Platform API. This plays a sound as specified in the registry. The *type* argument specifies which sound to play; possible values are `-1`, `MB_ICONASTERISK`, `MB_ICONEXCLAMATION`, `MB_ICONHAND`, `MB_ICONQUESTION`, and `MB_OK`, all described below. The value `-1` produces a “simple beep”; this is the final fallback if a sound cannot be played otherwise. If the system indicates

an error, `RuntimeError` is raised.

#### `winsound.SND_FILENAME`

The *sound* parameter is the name of a WAV file. Do not use with `SND_ALIAS`.

#### `winsound.SND_ALIAS`

The *sound* parameter is a sound association name from the registry. If the registry contains no such name, play the system default sound unless `SND_NODEFAULT` is also specified. If no default sound is registered, raise `RuntimeError`. Do not use with `SND_FILENAME`.

All Win32 systems support at least the following; most systems support many more:

<del>Corresponding Control</del>	Panel Sound name
Asterisk	Asterisk'
Exclamation	Exclamation'
Exit Window	Exit Window'
Critical Stop	Critical Stop'
Question	Question'

For example:

```
import winsound
# Play Windows exit sound.
winsound.PlaySound("SystemExit", winsound.SND_ALIAS

# Probably play Windows default sound, if any is re
# "*" probably isn't the registered name of any sou
winsound.PlaySound("*", winsound.SND_ALIAS)
```

#### `winsound.SND_LOOP`

Play the sound repeatedly. The `SND_ASYNC` flag must also be used to avoid blocking. Cannot be used with `SND_MEMORY`.

#### `winsound.SND_MEMORY`

The *sound* parameter to `PlaySound()` is a memory image of

a WAV file, as a [bytes-like object](#).

### **Note**

This module does not support playing from a memory image asynchronously, so a combination of this flag and [SND\\_ASYNC](#) will raise [RuntimeError](#).

`winsound.SND_PURGE`

Stop playing all instances of the specified sound.

### **Note**

This flag is not supported on modern Windows platforms.

`winsound.SND_ASYNC`

Return immediately, allowing sounds to play asynchronously.

`winsound.SND_NODEFAULT`

If the specified sound cannot be found, do not play the system default sound.

`winsound.SND_NOSTOP`

Do not interrupt sounds currently playing.

`winsound.SND_NOWAIT`

Return immediately if the sound driver is busy.

### **Note**

This flag is not supported on modern Windows platforms.

`winsound.MB_ICONASTERISK`

Play the `SystemDefault` sound.

winsound.MB\_ICONEXCLAMATION

Play the SystemExclamation sound.

winsound.MB\_ICONHAND

Play the SystemHand sound.

winsound.MB\_ICONQUESTION

Play the SystemQuestion sound.

winsound.MB\_OK

Play the SystemDefault sound.

# Unix Specific Services

The modules described in this chapter provide interfaces to features that are unique to the Unix operating system, or in some cases to some or many variants of it. Here's an overview:

- **posix** — The most common POSIX system calls
  - Large File Support
  - Notable Module Contents
- **pwd** — The password database
- **grp** — The group database
- **termios** — POSIX style tty control
  - Example
- **tty** — Terminal control functions
- **pty** — Pseudo-terminal utilities
  - Example
- **fcntl** — The **fcntl** and **ioctl** system calls
- **resource** — Resource usage information
  - Resource Limits
  - Resource Usage
- **syslog** — Unix syslog library routines
  - Examples
    - Simple example

# posix — The most common POSIX system calls

---

This module provides access to operating system functionality that is standardized by the C Standard and the POSIX standard (a thinly disguised Unix interface).

**Do not import this module directly.** Instead, import the module `os`, which provides a *portable* version of this interface. On Unix, the `os` module provides a superset of the `posix` interface. On non-Unix operating systems the `posix` module is not available, but a subset is always available through the `os` interface. Once `os` is imported, there is *no* performance penalty in using it instead of `posix`. In addition, `os` provides some additional functionality, such as automatically calling `putenv()` when an entry in `os.environ` is changed.

Errors are reported as exceptions; the usual exceptions are given for type errors, while errors reported by the system calls raise `OSError`.

## Large File Support

Several operating systems (including AIX and Solaris) provide support for files that are larger than 2 GiB from a C programming model where `int` and `long` are 32-bit values. This is typically accomplished by defining the relevant size and offset types as 64-bit values. Such files are sometimes referred to as *large files*.

Large file support is enabled in Python when the size of an `off_t` is larger than a `long` and the `long long` is at least as large as an `off_t`. It may be necessary to configure and compile Python with certain compiler flags to enable this mode. For example, with Solaris 2.6 and 2.7 you need to do something like:

```
CFLAGS="\`getconf LFS_CFLAGS`" OPT="-g -O2 $CFLAGS" \  
./configure
```

On large-file-capable Linux systems, this might work:

```
CFLAGS='-D_LARGEFILE64_SOURCE -D_FILE_OFFSET_BITS=64' OF  
./configure
```

## Notable Module Contents

In addition to many functions described in the `os` module documentation, `posix` defines the following data item:

`posix.envIRON`

A dictionary representing the string environment at the time the interpreter was started. Keys and values are bytes on Unix and str on Windows. For example, `environ[b'HOME']` (`environ['HOME']` on Windows) is the pathname of your home directory, equivalent to `getenv("HOME")` in C.

Modifying this dictionary does not affect the string environment passed on by `execv()`, `popen()` or `system()`; if you need to change the environment, pass `environ` to `execve()` or add variable assignments and export statements to the command string for `system()` or `popen()`.

*Changed in version 3.2:* On Unix, keys and values are bytes.

### Note

The `os` module provides an alternate implementation of `environ` which updates the environment on modification. Note also that updating `os.environ` will render this dictionary obsolete. Use of the `os` module version of this is recommended over direct access to the `posix` module.

# pwd — The password database

---

This module provides access to the Unix user account and password database. It is available on all Unix versions.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

Password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `passwd` structure (Attribute field below, see `<pwd.h>`):

## ~~Members~~

<del>login name</del>
<del>Optional encrypted password</del>
<del>Numerical user ID</del>
<del>Numerical group ID</del>
<del>Username or comment field</del>
<del>User home directory</del>
<del>User command interpreter</del>

The uid and gid items are integers, all others are strings.

**KeyError** is raised if the entry asked for cannot be found.

## Note

In traditional Unix the field `pw_passwd` usually contains a password encrypted with a DES derived algorithm (see module [crypt](#)). However most modern unices use a so-called *shadow password* system. On those unices the `pw_passwd` field only contains an asterisk ('\*') or the letter 'x' where the encrypted password is stored in a file `/etc/shadow` which is not world readable. Whether the `pw_passwd` field contains anything useful is

system-dependent. If available, the [spwd](#) module should be used where access to the encrypted password is required.

It defines the following items:

`pwd.getpwuid(uid)`

Return the password database entry for the given numeric user ID.

`pwd.getpwnam(name)`

Return the password database entry for the given user name.

`pwd.getpwall()`

Return a list of all available password database entries, in arbitrary order.

### See also

#### Module [grp](#)

An interface to the group database, similar to this.

#### Module [spwd](#)

An interface to the shadow password database, similar to this.

# grp — The group database

---

This module provides access to the Unix group database. It is available on all Unix versions.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

Group database entries are reported as a tuple-like object, whose attributes correspond to the members of the `group` structure (Attribute field below, see `<grp.h>`):

## Members

---

<code>gr_name</code>	name of the group
<code>gr_passwd</code>	(optional) group password; often empty
<code>gr_gid</code>	numerical group ID
<code>gr_mem</code>	group member's user names

---

The `gid` is an integer, `name` and `password` are strings, and the `member` list is a list of strings. (Note that most users are not explicitly listed as members of the group they are in according to the password database. Check both databases to get complete membership information. Also note that a `gr_name` that starts with a `+` or `-` is likely to be a YP/NIS reference and may not be accessible via `getgrnam()` or `getgrgid().`)

It defines the following items:

`grp.getgrgid(id)`

Return the group database entry for the given numeric group ID. **KeyError** is raised if the entry asked for cannot be found.

*Changed in version 3.10:* `TypeError` is raised for non-integer arguments like floats or strings.

`grp.getgrnam(name)`

Return the group database entry for the given group name.  
`KeyError` is raised if the entry asked for cannot be found.

`grp.getgrall()`

Return a list of all available group entries, in arbitrary order.

An interface to the user database, similar to this.

#### Module `spwd`

An interface to the shadow password database, similar to this.

# `termios` — POSIX style tty control

---

This module provides an interface to the POSIX calls for tty I/O control. For a complete description of these calls, see [termios\(3\)](#) Unix manual page. It is only available for those Unix versions that support POSIX *termios* style tty I/O control configured during installation.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a [file object](#), such as `sys.stdin` itself.

This module also defines all the constants needed to work with the functions provided here; these have the same name as their counterparts in C. Please refer to your system documentation for more information on using these terminal control interfaces.

The module defines the following functions:

`termios.tcgetattr(fd)`

Return a list containing the tty attributes for file descriptor *fd*, as follows: [*iflag*, *oflag*, *cflag*, *lflag*, *ispeed*, *ospeed*, *cc*] where *cc* is a list of the tty special characters (each a string of length 1, except the items with indices **VMIN** and **VTIME**, which are integers when these fields are defined). The interpretation of the flags and the speeds as well as the indexing in the *cc* array must be done using the symbolic constants defined in the [termios](#) module.

`termios.tcsetattr(fd, when, attributes)`

Set the tty attributes for file descriptor *fd* from the *attributes*, which is a list like the one returned by [tcgetattr\(\)](#). The *when* argument determines when the attributes are changed:

**TCSANOW** to change immediately, **TCSADRAIN** to change after transmitting all queued output, or **TCSAFLUSH** to change after transmitting all queued output and discarding all queued input.

`termios.tcsendbreak(fd, duration)`

Send a break on file descriptor *fd*. A zero *duration* sends a break for 0.25–0.5 seconds; a nonzero *duration* has a system dependent meaning.

`termios.tcdrain(fd)`

Wait until all output written to file descriptor *fd* has been transmitted.

`termios.tcflush(fd, queue)`

Discard queued data on file descriptor *fd*. The *queue* selector specifies which queue: **TCIFLUSH** for the input queue, **TCOFLUSH** for the output queue, or **TCIOFLUSH** for both queues.

`termios.tcflow(fd, action)`

Suspend or resume input or output on file descriptor *fd*. The *action* argument can be **TCOOFF** to suspend output, **TCOON** to restart output, **TCIOFF** to suspend input, or **TCION** to restart input.

`termios.tcgetwinsize(fd)`

Return a tuple (*ws\_row*, *ws\_col*) containing the tty window size for file descriptor *fd*. Requires **termios.TIOCGWINSZ** or **termios.TIOCGSIZE**.

*New in version 3.11.*

`termios.tcsetwinsize(fd, winsize)`

Set the tty window size for file descriptor *fd* from *winsize*, which is a two-item tuple (*ws\_row*, *ws\_col*) like the one returned by `tcgetwinsize()`. Requires at least one of the

pairs (`termios.TIOCGWINSZ`, `termios.TIOCSWINSZ`); (`termios.TIOCGSIZE`, `termios.TIOCSSIZE`) to be defined.

*New in version 3.11.*

## See also

### Module `tty`

Convenience functions for common terminal control operations.

## Example

Here's a function that prompts for a password with echoing turned off. Note the technique using a separate `tcgetattr()` call and a `try ... finally` statement to ensure that the old `tty` attributes are restored exactly no matter what happens:

```
def getpass(prompt="Password: "):
    import termios, sys
    fd = sys.stdin.fileno()
    old = termios.tcgetattr(fd)
    new = termios.tcgetattr(fd)
    new[3] = new[3] & ~termios.ECHO           # lflags
    try:
        termios.tcsetattr(fd, termios.TCSADRAIN, new)
        passwd = input(prompt)
    finally:
        termios.tcsetattr(fd, termios.TCSADRAIN, old)
    return passwd
```

# tty — Terminal control functions

**Source code:** [Lib/tty.py](https://github.com/python/cpython/tree/3.12/Lib/tty.py) [https://github.com/python/cpython/tree/3.12/Lib/tty.py]

---

The **tty** module defines functions for putting the tty into cbreak and raw modes.

Because it requires the **termios** module, it will work only on Unix.

The **tty** module defines the following functions:

**tty.cfmakeraw(mode)**

Convert the tty attribute list *mode*, which is a list like the one returned by **termios.tcgetattr()**, to that of a tty in raw mode.

*New in version 3.12.*

**tty.cfmakecbreak(mode)**

Convert the tty attribute list *mode*, which is a list like the one returned by **termios.tcgetattr()**, to that of a tty in cbreak mode.

*New in version 3.12.*

**tty.setraw(fd, when = termios.TCSAFLUSH)**

Change the mode of the file descriptor *fd* to raw. If *when* is omitted, it defaults to **termios.TCSAFLUSH**, and is passed to **termios.tcsetattr()**. The return value of **termios.tcgetattr()** is saved before setting *fd* to raw mode; this value is returned.

*Changed in version 3.12:* The return value is now the original tty attributes, instead of None.

`tty.setcbreak(fd, when = termios.TCSAFLUSH)`

Change the mode of file descriptor *fd* to cbreak. If *when* is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`. The return value of `termios.tcgetattr()` is saved before setting *fd* to cbreak mode; this value is returned.

*Changed in version 3.12:* The return value is now the original tty attributes, instead of None.

**See also**

**Module** `termios`

Low-level terminal control interface.

# pty — Pseudo-terminal utilities

**Source code:** [Lib/pty.py](https://github.com/python/cpython/tree/3.12/Lib/pty.py) [https://github.com/python/cpython/tree/3.12/Lib/pty.py]

---

The **pty** module defines operations for handling the pseudo-terminal concept: starting another process and being able to write to and read from its controlling terminal programmatically.

Pseudo-terminal handling is highly platform dependent. This code is mainly tested on Linux, FreeBSD, and macOS (it is supposed to work on other POSIX platforms but it's not been thoroughly tested).

The **pty** module defines the following functions:

`pty.fork()`

Fork. Connect the child's controlling terminal to a pseudo-terminal. Return value is `(pid, fd)`. Note that the child gets *pid* 0, and the *fd* is *invalid*. The parent's return value is the *pid* of the child, and *fd* is a file descriptor connected to the child's controlling terminal (and also to the child's standard input and output).

`pty.openpty()`

Open a new pseudo-terminal pair, using `os.openpty()` if possible, or emulation code for generic Unix systems. Return a pair of file descriptors `(master, slave)`, for the master and the slave end, respectively.

`pty.spawn(argv[, master_read[, stdin_read]])`

Spawn a process, and connect its controlling terminal with the current process's standard io. This is often used to baffle programs which insist on reading from the controlling terminal. It is expected that the process spawned behind the

pty will eventually terminate, and when it does *spawn* will return.

A loop copies STDIN of the current process to the child and data received from the child to STDOUT of the current process. It is not signaled to the child if STDIN of the current process closes down.

The functions *master\_read* and *stdin\_read* are passed a file descriptor which they should read from, and they should always return a byte string. In order to force *spawn* to return before the child process exits an empty byte array should be returned to signal end of file.

The default implementation for both functions will read and return up to 1024 bytes each time the function is called. The *master\_read* callback is passed the pseudoterminal's master file descriptor to read output from the child process, and *stdin\_read* is passed file descriptor 0, to read from the parent process's standard input.

Returning an empty byte string from either callback is interpreted as an end-of-file (EOF) condition, and that callback will not be called after that. If *stdin\_read* signals EOF the controlling terminal can no longer communicate with the parent process OR the child process. Unless the child process will quit without any input, *spawn* will then loop forever. If *master\_read* signals EOF the same behavior results (on linux at least).

Return the exit status value from `os.waitpid()` on the child process.

`os.waitstatus_to_exitcode()` can be used to convert the exit status into an exit code.

Raises an `auditing event` `pty.spawn` with argument `argv`.

*Changed in version 3.4:* `spawn()` now returns the status value from `os.waitpid()` on the child process.

# Example

The following program acts like the Unix command *script(1)*, using a pseudo-terminal to record all input and output of a terminal session in a “typescript”.

```
import argparse
import os
import pty
import sys
import time

parser = argparse.ArgumentParser()
parser.add_argument('-a', dest='append', action='store_true')
parser.add_argument('-p', dest='use_python', action='store_true')
parser.add_argument('filename', nargs='?', default='typescript')
options = parser.parse_args()

shell = sys.executable if options.use_python else os.environ['SHELL']
filename = options.filename
mode = 'ab' if options.append else 'wb'

with open(filename, mode) as script:
    def read(fd):
        data = os.read(fd, 1024)
        script.write(data)
        return data

    print('Script started, file is', filename)
    script.write(('Script started on %s\n' % time.asctime()))

    pty.spawn(shell, read)

    script.write(('Script done on %s\n' % time.asctime()))
    print('Script done, file is', filename)
```

# fcntl — The fcntl and ioctl system calls

---

This module performs file control and I/O control on file descriptors. It is an interface to the `fcntl()` and `ioctl()` Unix routines. For a complete description of these calls, see [fcntl\(2\)](#) and [ioctl\(2\)](#) Unix manual pages.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emsripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

All functions in this module take a file descriptor `fd` as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or an `io.IOBase` object, such as `sys.stdin` itself, which provides a `fileno()` that returns a genuine file descriptor.

*Changed in version 3.3:* Operations in this module used to raise an `IOError` where they now raise an `OSError`.

*Changed in version 3.8:* The `fcntl` module now contains `F_ADD_SEALS`, `F_GET_SEALS`, and `F_SEAL_*` constants for sealing of `os.memfd_create()` file descriptors.

*Changed in version 3.9:* On macOS, the `fcntl` module exposes the `F_GETPATH` constant, which obtains the path of a file from a file descriptor. On Linux ( $\geq 3.15$ ), the `fcntl` module exposes the `F_OFD_GETLK`, `F_OFD_SETLK` and `F_OFD_SETLKW` constants, which are used when working with open file description locks.

*Changed in version 3.10:* On Linux  $\geq 2.6.11$ , the `fcntl` module exposes the `F_GETPIPE_SZ` and `F_SETPIPE_SZ` constants, which

allow to check and modify a pipe's size respectively.

*Changed in version 3.11:* On FreeBSD, the `fcntl` module exposes the `F_DUP2FD` and `F_DUP2FD_CLOEXEC` constants, which allow to duplicate a file descriptor, the latter setting `FD_CLOEXEC` flag in addition.

*Changed in version 3.12:* On Linux  $\geq 4.5$ , the `fcntl` module exposes the `FICLONE` and `FICLONERANGE` constants, which allow to share some data of one file with another file by reflinking on some filesystems (e.g., `btrfs`, `OCFS2`, and `XFS`). This behavior is commonly referred to as “copy-on-write”.

The module defines the following functions:

`fcntl.fcntl(fd, cmd, arg=0)`

Perform the operation `cmd` on file descriptor `fd` (file objects providing a `fileno()` method are accepted as well). The values used for `cmd` are operating system dependent, and are available as constants in the `fcntl` module, using the same names as used in the relevant C header files. The argument `arg` can either be an integer value, or a `bytes` object. With an integer value, the return value of this function is the integer return value of the C `fcntl()` call. When the argument is bytes it represents a binary structure, e.g. created by `struct.pack()`. The binary data is copied to a buffer whose address is passed to the C `fcntl()` call. The return value after a successful call is the contents of the buffer, converted to a `bytes` object. The length of the returned object will be the same as the length of the `arg` argument. This is limited to 1024 bytes. If the information returned in the buffer by the operating system is larger than 1024 bytes, this is most likely to result in a segmentation violation or a more subtle data corruption.

If the `fcntl()` fails, an `OSError` is raised.

Raises an `auditing event` `fcntl.fcntl` with arguments `fd`, `cmd`, `arg`.

`fcntl.ioctl(fd, request, arg=0, mutate_flag=True)`

This function is identical to the `fcntl()` function, except that the argument handling is even more complicated.

The *request* parameter is limited to values that can fit in 32-bits. Additional constants of interest for use as the *request* argument can be found in the `termios` module, under the same names as used in the relevant C header files.

The parameter *arg* can be one of an integer, an object supporting the read-only buffer interface (like `bytes`) or an object supporting the read-write buffer interface (like `bytearray`).

In all but the last case, behaviour is as for the `fcntl()` function.

If a mutable buffer is passed, then the behaviour is determined by the value of the *mutate\_flag* parameter.

If it is false, the buffer's mutability is ignored and behaviour is as for a read-only buffer, except that the 1024 byte limit mentioned above is avoided – so long as the buffer you pass is at least as long as what the operating system wants to put there, things should work.

If *mutate\_flag* is true (the default), then the buffer is (in effect) passed to the underlying `ioctl()` system call, the latter's return code is passed back to the calling Python, and the buffer's new contents reflect the action of the `ioctl()`. This is a slight simplification, because if the supplied buffer is less than 1024 bytes long it is first copied into a static buffer 1024 bytes long which is then passed to `ioctl()` and copied back into the supplied buffer.

If the `ioctl()` fails, an `OSError` exception is raised.

An example:

```
>>> import array, fcntl, struct, termios, os
>>> os.getpgrp()
```

```

13341
>>> struct.unpack('h', fcntl.ioctl(0, termios.TIOCG
13341
>>> buf = array.array('h', [0])
>>> fcntl.ioctl(0, termios.TIOCGPGRP, buf, 1)
0
>>> buf
array('h', [13341])

```

Raises an [auditing event](#) `fcntl.ioctl` with arguments `fd`, `request`, `arg`.

### `fcntl.flock(fd, operation)`

Perform the lock operation *operation* on file descriptor *fd* (file objects providing a [fileno\(\)](#) method are accepted as well). See the Unix manual [flock\(2\)](#) for details. (On some systems, this function is emulated using `fcntl().`)

If the `flock()` fails, an [OSError](#) exception is raised.

Raises an [auditing event](#) `fcntl.flock` with arguments `fd`, `operation`.

### `fcntl.lockf(fd, cmd, len=0, start=0, whence=0)`

This is essentially a wrapper around the `fcntl()` locking calls. *fd* is the file descriptor (file objects providing a [fileno\(\)](#) method are accepted as well) of the file to lock or unlock, and *cmd* is one of the following values:

- **LOCK\_UN** – unlock
- **LOCK\_SH** – acquire a shared lock
- **LOCK\_EX** – acquire an exclusive lock

When *cmd* is **LOCK\_SH** or **LOCK\_EX**, it can also be bitwise ORed with **LOCK\_NB** to avoid blocking on lock acquisition. If **LOCK\_NB** is used and the lock cannot be acquired, an [OSError](#) will be raised and the exception will have an *errno* attribute set to **EACCES** or **EAGAIN** (depending on the operating system; for portability, check for both values). On

at least some systems, **LOCK\_EX** can only be used if the file descriptor refers to a file opened for writing.

*len* is the number of bytes to lock, *start* is the byte offset at which the lock starts, relative to *whence*, and *whence* is as with `io.IOBase.seek()`, specifically:

- 0 – relative to the start of the file (`os.SEEK_SET`)
- 1 – relative to the current buffer position (`os.SEEK_CUR`)
- 2 – relative to the end of the file (`os.SEEK_END`)

The default for *start* is 0, which means to start at the beginning of the file. The default for *len* is 0 which means to lock to the end of the file. The default for *whence* is also 0.

Raises an [auditing event](#) `fcntl.lockf` with arguments `fd`, `cmd`, `len`, `start`, `whence`.

Examples (all on a SVR4 compliant system):

```
import struct, fcntl, os

f = open(...)
rv = fcntl.fcntl(f, fcntl.F_SETFL, os.O_NDELAY)

lockdata = struct.pack('hhllhh', fcntl.F_WRLCK, 0, 0, 0, 0, 0)
rv = fcntl.fcntl(f, fcntl.F_SETLKW, lockdata)
```

Note that in the first example the return value variable *rv* will hold an integer value; in the second example it will hold a [bytes](#) object. The structure lay-out for the *lockdata* variable is system dependent — therefore using the `flock()` call may be better.

**See also**

## Module `os`

If the locking flags `O_SHLOCK` and `O_EXLOCK` are present in the `os` module (on BSD only), the `os.open()` function provides an alternative to the `lockf()` and

`flock()` functions.

# resource — Resource usage information

---

This module provides basic mechanisms for measuring and controlling system resources utilized by a program.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

Symbolic constants are used to specify particular system resources and to request usage information about either the current process or its children.

An **OSError** is raised on syscall failure.

*exception* resource.error

A deprecated alias of **OSError**.

*Changed in version 3.3:* Following [PEP 3151](https://peps.python.org/pep-3151/) [https://peps.python.org/pep-3151/], this class was made an alias of **OSError**.

## Resource Limits

Resources usage can be limited using the **setrlimit()** function described below. Each resource is controlled by a pair of limits: a soft limit and a hard limit. The soft limit is the current limit, and may be lowered or raised by a process over time. The soft limit can never exceed the hard limit. The hard limit can be lowered to any value greater than the soft limit, but not raised. (Only processes with the effective UID of the super-user can raise a hard limit.)

The specific resources that can be limited are system dependent. They are described in the [getrlimit\(2\)](#) man page. The resources listed below are supported when the underlying operating system supports them; resources which cannot be checked or controlled by the operating system are not defined in this module for those platforms.

`resource.RLIM_INFINITY`

Constant used to represent the limit for an unlimited resource.

`resource.getrlimit(resource)`

Returns a tuple (soft, hard) with the current soft and hard limits of *resource*. Raises **ValueError** if an invalid resource is specified, or **error** if the underlying system call fails unexpectedly.

`resource.setrlimit(resource, limits)`

Sets new limits of consumption of *resource*. The *limits* argument must be a tuple (soft, hard) of two integers describing the new limits. A value of **RLIM\_INFINITY** can be used to request a limit that is unlimited.

Raises **ValueError** if an invalid resource is specified, if the new soft limit exceeds the hard limit, or if a process tries to raise its hard limit. Specifying a limit of **RLIM\_INFINITY** when the hard or system limit for that resource is not unlimited will result in a **ValueError**. A process with the effective UID of super-user can request any valid limit value, including unlimited, but **ValueError** will still be raised if the requested limit exceeds the system imposed limit.

`setrlimit` may also raise **error** if the underlying system call fails.

VxWorks only supports setting **RLIMIT\_NOFILE**.

Raises an **auditing event** `resource.setrlimit` with arguments `resource, limits`.

`resource.prlimit(pid, resource[, limits])`

Combines `setrlimit()` and `getrlimit()` in one function and supports to get and set the resources limits of an arbitrary process. If *pid* is 0, then the call applies to the current process. *resource* and *limits* have the same meaning as in `setrlimit()`, except that *limits* is optional.

When *limits* is not given the function returns the *resource* limit of the process *pid*. When *limits* is given the *resource* limit of the process is set and the former resource limit is returned.

Raises `ProcessLookupError` when *pid* can't be found and `PermissionError` when the user doesn't have `CAP_SYS_RESOURCE` for the process.

Raises an `auditing event` `resource.prlimit` with arguments `pid`, `resource`, `limits`.

**Availability:** Linux  $\geq$  2.6.36 with glibc  $\geq$  2.13.

*New in version 3.4.*

These symbols define resources whose consumption can be controlled using the `setrlimit()` and `getrlimit()` functions described below. The values of these symbols are exactly the constants used by C programs.

The Unix man page for `getrlimit(2)` lists the available resources. Note that not all systems use the same symbol or same value to denote the same resource. This module does not attempt to mask platform differences — symbols not defined for a platform will not be available from this module on that platform.

`resource.RLIMIT_CORE`

The maximum size (in bytes) of a core file that the current process can create. This may result in the creation of a partial core file if a larger core would be required to contain the entire process image.

`resource.RLIMIT_CPU`

The maximum amount of processor time (in seconds) that a process can use. If this limit is exceeded, a **SIGXCPU** signal is sent to the process. (See the [signal](#) module documentation for information about how to catch this signal and do something useful, e.g. flush open files to disk.)

resource.RLIMIT\_FSIZE

The maximum size of a file which the process may create.

resource.RLIMIT\_DATA

The maximum size (in bytes) of the process's heap.

resource.RLIMIT\_STACK

The maximum size (in bytes) of the call stack for the current process. This only affects the stack of the main thread in a multi-threaded process.

resource.RLIMIT\_RSS

The maximum resident set size that should be made available to the process.

resource.RLIMIT\_NPROC

The maximum number of processes the current process may create.

resource.RLIMIT\_NOFILE

The maximum number of open file descriptors for the current process.

resource.RLIMIT\_OFILE

The BSD name for [RLIMIT\\_NOFILE](#).

resource.RLIMIT\_MEMLOCK

The maximum address space which may be locked in memory.

resource.RLIMIT\_VMEM

The largest area of mapped memory which the process may occupy.

resource.RLIMIT\_AS

The maximum area (in bytes) of address space which may be taken by the process.

resource.RLIMIT\_MSGQUEUE

The number of bytes that can be allocated for POSIX message queues.

**Availability:** Linux  $\geq$  2.6.8.

*New in version 3.4.*

resource.RLIMIT\_NICE

The ceiling for the process's nice level (calculated as  $20 - \text{rlim\_cur}$ ).

**Availability:** Linux  $\geq$  2.6.12.

*New in version 3.4.*

resource.RLIMIT\_RTPRIO

The ceiling of the real-time priority.

**Availability:** Linux  $\geq$  2.6.12.

*New in version 3.4.*

resource.RLIMIT\_RTTIME

The time limit (in microseconds) on CPU time that a process can spend under real-time scheduling without making a blocking syscall.

**Availability:** Linux  $\geq$  2.6.25.

*New in version 3.4.*

#### resource.RLIMIT\_SIGPENDING

The number of signals which the process may queue.

**Availability:** Linux  $\geq$  2.6.8.

*New in version 3.4.*

#### resource.RLIMIT\_SBSIZE

The maximum size (in bytes) of socket buffer usage for this user. This limits the amount of network memory, and hence the amount of mbufs, that this user may hold at any time.

**Availability:** FreeBSD.

*New in version 3.4.*

#### resource.RLIMIT\_SWAP

The maximum size (in bytes) of the swap space that may be reserved or used by all of this user id's processes. This limit is enforced only if bit 1 of the vm.overcommit sysctl is set.

Please see [tuning\(7\)](https://man.freebsd.org/cgi/man.cgi?query=tuning&sektion=7) [https://man.freebsd.org/cgi/man.cgi?query=tuning&sektion=7] for a complete description of this sysctl.

**Availability:** FreeBSD.

*New in version 3.4.*

#### resource.RLIMIT\_NPTS

The maximum number of pseudo-terminals created by this user id.

**Availability:** FreeBSD.

*New in version 3.4.*

#### resource.RLIMIT\_KQUEUES

The maximum number of kqueues this user id is allowed to create.

**Availability:** FreeBSD >= 11.

*New in version 3.10.*

## Resource Usage

These functions are used to retrieve resource usage information:

`resource.getrusage(who)`

This function returns an object that describes the resources consumed by either the current process or its children, as specified by the *who* parameter. The *who* parameter should be specified using one of the **RUSAGE\_\*** constants described below.

A simple example:

```
from resource import *
import time

# a non CPU-bound task
time.sleep(3)
print(getrusage(RUSAGE_SELF))

# a CPU-bound task
for i in range(10 ** 8):
    _ = 1 + 1
print(getrusage(RUSAGE_SELF))
```

The fields of the return value each describe how a particular system resource has been used, e.g. amount of time spent running in user mode or number of times the process was swapped out of main memory. Some values are dependent on the clock tick interval, e.g. the amount of memory the process is using.

For backward compatibility, the return value is also accessible as a tuple of 16 elements.

The fields **ru\_utime** and **ru\_stime** of the return value are

floating point values representing the amount of time spent executing in user mode and the amount of time spent executing in system mode, respectively. The remaining values are integers. Consult the [getrusage\(2\)](#) man page for detailed information about these values. A brief summary is presented here:

### Resource

<del>time in user</del>	time in user mode (float seconds)
<del>time in sys</del>	time in system mode (float seconds)
<del>maxrss</del>	maximum resident set size
<del>sharedrss</del>	shared memory size
<del>unsharedrss</del>	unshared memory size
<del>unsharedst</del>	unshared stack size
<del>pgfault</del>	page faults not requiring I/O
<del>pgmajflt</del>	page faults requiring I/O
<del>swapout</del>	number of swap outs
<del>blockio</del>	block operations
<del>blockop</del>	block operations
<del>msgsnd</del>	messages sent
<del>msgrcv</del>	messages received
<del>signals</del>	signals received
<del>voluntary</del>	voluntary context switches
<del>involuntary</del>	involuntary context switches

This function will raise a **ValueError** if an invalid *who* parameter is specified. It may also raise **error** exception in unusual circumstances.

`resource.getpagesize()`

Returns the number of bytes in a system page. (This need not be the same as the hardware page size.)

The following **RUSAGE\_\*** symbols are passed to the [getrusage\(\)](#) function to specify which processes information should be provided for.

`resource.RUSAGE_SELF`

Pass to [getrusage\(\)](#) to request resources consumed by the calling process, which is the sum of resources used by all

threads in the process.

resource.RUSAGE\_CHILDREN

Pass to `getrusage()` to request resources consumed by child processes of the calling process which have been terminated and waited for.

resource.RUSAGE\_BOTH

Pass to `getrusage()` to request resources consumed by both the current process and child processes. May not be available on all systems.

resource.RUSAGE\_THREAD

Pass to `getrusage()` to request resources consumed by the current thread. May not be available on all systems.

*New in version 3.2.*

# syslog — Unix syslog library routines

---

This module provides an interface to the Unix `syslog` library routines. Refer to the Unix manual pages for a detailed description of the `syslog` facility.

This module wraps the system `syslog` family of routines. A pure Python library that can speak to a syslog server is available in the `logging.handlers` module as `SysLogHandler`.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscrip`ten and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

The module defines the following functions:

`syslog.syslog(message)`

`syslog.syslog(priority, message)`

Send the string *message* to the system logger. A trailing newline is added if necessary. Each message is tagged with a priority composed of a *facility* and a *level*. The optional *priority* argument, which defaults to `LOG_INFO`, determines the message priority. If the facility is not encoded in *priority* using logical-or (`LOG_INFO | LOG_USER`), the value given in the `openlog()` call is used.

If `openlog()` has not been called prior to the call to `syslog()`, `openlog()` will be called with no arguments.

Raises an [auditing event](#) `syslog.syslog` with arguments `priority`, `message`.

*Changed in version 3.2:* In previous versions, `openlog()` would not be called automatically if it wasn't called prior to the call to `syslog()`, deferring to the syslog implementation to call `openlog()`.

*Changed in version 3.12:* This function is restricted in subinterpreters. (Only code that runs in multiple interpreters is affected and the restriction is not relevant for most users.) `openlog()` must be called in the main interpreter before `syslog()` may be used in a subinterpreter. Otherwise it will raise `RuntimeError`.

`syslog.openlog([ident[, logoption[, facility]]])`

Logging options of subsequent `syslog()` calls can be set by calling `openlog()`. `syslog()` will call `openlog()` with no arguments if the log is not currently open.

The optional *ident* keyword argument is a string which is prepended to every message, and defaults to `sys.argv[0]` with leading path components stripped. The optional *logoption* keyword argument (default is 0) is a bit field – see below for possible values to combine. The optional *facility* keyword argument (default is `LOG_USER`) sets the default facility for messages which do not have a facility explicitly encoded.

Raises an `auditing event` `syslog.openlog` with arguments *ident*, *logoption*, *facility*.

*Changed in version 3.2:* In previous versions, keyword arguments were not allowed, and *ident* was required.

*Changed in version 3.12:* This function is restricted in subinterpreters. (Only code that runs in multiple interpreters is affected and the restriction is not relevant for most users.) This may only be called in the main interpreter. It will raise `RuntimeError` if called in a subinterpreter.

`syslog.closelog()`

Reset the syslog module values and call the system library `closelog()`.

This causes the module to behave as it does when initially imported. For example, `openlog()` will be called on the first `syslog()` call (if `openlog()` hasn't already been called), and `ident` and other `openlog()` parameters are reset to defaults.

Raises an **auditing event** `syslog.closelog` with no arguments.

*Changed in version 3.12:* This function is restricted in subinterpreters. (Only code that runs in multiple interpreters is affected and the restriction is not relevant for most users.) This may only be called in the main interpreter. It will raise **RuntimeError** if called in a subinterpreter.

`syslog.setlogmask(maskpri)`

Set the priority mask to `maskpri` and return the previous mask value. Calls to `syslog()` with a priority level not set in `maskpri` are ignored. The default is to log all priorities. The function `LOG_MASK(pri)` calculates the mask for the individual priority `pri`. The function `LOG_UPTO(pri)` calculates the mask for all priorities up to and including `pri`.

Raises an **auditing event** `syslog.setlogmask` with argument `maskpri`.

The module defines the following constants:

Priority levels (high to low):

`LOG_EMERG`, `LOG_ALERT`, `LOG_CRIT`, `LOG_ERR`,  
`LOG_WARNING`, `LOG_NOTICE`, `LOG_INFO`, `LOG_DEBUG`.

Facilities:

`LOG_KERN`, `LOG_USER`, `LOG_MAIL`, `LOG_DAEMON`,  
`LOG_AUTH`, `LOG_LPR`, `LOG_NEWS`, `LOG_UUCP`, `LOG_CRON`,  
`LOG_SYSLOG`, `LOG_LOCAL0` to `LOG_LOCAL7`, and, if  
defined in `<syslog.h>`, `LOG_AUTHPRIV`.

Log options:

`LOG_PID`, `LOG_CONS`, `LOG_NDELAY`, and, if defined in

<syslog.h>, **LOG\_ODELAY**, **LOG\_NOWAIT**, and **LOG\_PERROR**.

## Examples

### Simple example

A simple set of examples:

```
import syslog

syslog.syslog('Processing started')
if error:
    syslog.syslog(syslog.LOG_ERR, 'Processing started')
```

An example of setting some log options, these would include the process ID in logged messages, and write the messages to the destination facility used for mail logging:

```
syslog.openlog(logoption=syslog.LOG_PID, facility=syslog.LOG_MAIL)
syslog.syslog('E-mail processing initiated...')
```

# Modules command-line interface (CLI)

The following modules have a command-line interface.

- `ast`
- `asyncio`
- `base64`
- `calendar`
- `code`
- `compileall`
- `cProfile`: see `profile`
- `difflib`
- `dis`
- `doctest`
- `encodings.rot_13`
- `ensurepip`
- `filecmp`
- `fileinput`
- `ftplib`
- `gzip`
- `http.server`
- `idlelib`
- `inspect`
- `json.tool`
- `mimetypes`
- `pdb`
- `pickle`
- `pickletools`
- `platform`
- `poplib`
- `profile`
- `pstats`
- `py_compile`
- `pyclbr`

- `pydoc`
- `quopri`
- `runpy`
- `site`
- `sqlite3`
- `sysconfig`
- `tabnanny`
- `tarfile`
- `this`
- `timeit`
- `tokenize`
- `trace`
- `turtledemo`
- `unittest`
- `uuid`
- `venv`
- `webbrowser`
- `zipapp`
- `zipfile`

See also the [Python command-line interface](#).

# Superseded Modules

The modules described in this chapter are deprecated and only kept for backwards compatibility. They have been superseded by other modules.

- **aifc** — Read and write AIFF and AIFC files
- **audioop** — Manipulate raw audio data
- **cgi** — Common Gateway Interface support
- **cgitb** — Traceback manager for CGI scripts
- **chunk** — Read IFF chunked data
- **crypt** — Function to check Unix passwords
- **imghdr** — Determine the type of an image
- **mailcap** — Mailcap file handling
- **msilib** — Read and write Microsoft Installer files
- **nis** — Interface to Sun's NIS (Yellow Pages)
- **nntplib** — NNTP protocol client
- **optparse** — Parser for command line options
- **ossaudiodev** — Access to OSS-compatible audio devices
- **pipes** — Interface to shell pipelines
- **sndhdr** — Determine type of sound file
- **spwd** — The shadow password database
- **sunau** — Read and write Sun AU files
- **telnetlib** — Telnet client
- **uu** — Encode and decode uuencode files
- **xdrlib** — Encode and decode XDR data

# aifc — Read and write AIFF and AIFC files

**Source code:** [Lib/aifc.py](https://github.com/python/cpython/tree/3.12/Lib/aifc.py) [https://github.com/python/cpython/tree/3.12/Lib/aifc.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **aifc** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#aifc) [https://peps.python.org/pep-0594/#aifc] for details).

---

This module provides support for reading and writing AIFF and AIFF-C files. AIFF is Audio Interchange File Format, a format for storing digital audio samples in a file. AIFF-C is a newer version of the format that includes the ability to compress the audio data.

Audio files have a number of parameters that describe the audio data. The sampling rate or frame rate is the number of times per second the sound is sampled. The number of channels indicate if the audio is mono, stereo, or quadro. Each frame consists of one sample per channel. The sample size is the size in bytes of each sample. Thus a frame consists of `nchannels * samplesize` bytes, and a second's worth of audio consists of `nchannels * samplesize * framerate` bytes.

For example, CD quality audio has a sample size of two bytes (16 bits), uses two channels (stereo) and has a frame rate of 44,100 frames/second. This gives a frame size of 4 bytes (2\*2), and a second's worth occupies 2\*2\*44100 bytes (176,400 bytes).

Module **aifc** defines the following function:

`aifc.open(file, mode=None)`

Open an AIFF or AIFF-C file and return an object instance with methods that are described below. The argument *file* is either a string naming a file or a [file object](#). *mode* must be

'r' or 'rb' when the file must be opened for reading, or 'w' or 'wb' when the file must be opened for writing. If omitted, `file.mode` is used if it exists, otherwise 'rb' is used. When used for writing, the file object should be seekable, unless you know ahead of time how many samples you are going to write in total and use `writeframesraw()` and `setnframes()`. The `open()` function may be used in a `with` statement. When the `with` block completes, the `close()` method is called.

*Changed in version 3.4:* Support for the `with` statement was added.

Objects returned by `open()` when a file is opened for reading have the following methods:

`aifc.getnchannels()`

Return the number of audio channels (1 for mono, 2 for stereo).

`aifc.getsampwidth()`

Return the size in bytes of individual samples.

`aifc.getframerate()`

Return the sampling rate (number of audio frames per second).

`aifc.getnframes()`

Return the number of audio frames in the file.

`aifc.getcomptype()`

Return a bytes array of length 4 describing the type of compression used in the audio file. For AIFF files, the returned value is `b'NONE'`.

`aifc.getcompname()`

Return a bytes array convertible to a human-readable

description of the type of compression used in the audio file. For AIFF files, the returned value is `b'not compressed'`.

`aifc.getparams()`

Returns a `namedtuple()` (`nchannels`, `sampwidth`, `framerate`, `nframes`, `comptype`, `compname`), equivalent to output of the `get*()` methods.

`aifc.getmarkers()`

Return a list of markers in the audio file. A marker consists of a tuple of three elements. The first is the mark ID (an integer), the second is the mark position in frames from the beginning of the data (an integer), the third is the name of the mark (a string).

`aifc.getmark(id)`

Return the tuple as described in `getmarkers()` for the mark with the given `id`.

`aifc.readframes(nframes)`

Read and return the next *nframes* frames from the audio file. The returned data is a string containing for each frame the uncompressed samples of all channels.

`aifc.rewind()`

Rewind the read pointer. The next `readframes()` will start from the beginning.

`aifc.setpos(pos)`

Seek to the specified frame number.

`aifc.tell()`

Return the current frame number.

`aifc.close()`

Close the AIFF file. After calling this method, the object can no longer be used.

Objects returned by `open()` when a file is opened for writing have all the above methods, except for `readframes()` and `setpos()`. In addition the following methods exist. The `get*()` methods can only be called after the corresponding `set*()` methods have been called. Before the first `writeframes()` or `writeframesraw()`, all parameters except for the number of frames must be filled in.

`aifc.aiff()`

Create an AIFF file. The default is that an AIFF-C file is created, unless the name of the file ends in `'.aiff'` in which case the default is an AIFF file.

`aifc.aifc()`

Create an AIFF-C file. The default is that an AIFF-C file is created, unless the name of the file ends in `'.aiff'` in which case the default is an AIFF file.

`aifc.setnchannels(nchannels)`

Specify the number of channels in the audio file.

`aifc.setsampwidth(width)`

Specify the size in bytes of audio samples.

`aifc.setframerate(rate)`

Specify the sampling frequency in frames per second.

`aifc.setnframes(nframes)`

Specify the number of frames that are to be written to the audio file. If this parameter is not set, or not set correctly, the file needs to support seeking.

`aifc.setcomptype(type, name)`

Specify the compression type. If not specified, the audio data

will not be compressed. In AIFF files, compression is not possible. The name parameter should be a human-readable description of the compression type as a bytes array, the type parameter should be a bytes array of length 4. Currently the following compression types are supported: `b'NONE'`, `b'ULAW'`, `b'ALAW'`, `b'G722'`.

`aifc.setparams(nchannels, sampwidth, framerate, comptype, compname)`

Set all the above parameters at once. The argument is a tuple consisting of the various parameters. This means that it is possible to use the result of a `getparams()` call as argument to `setparams()`.

`aifc.setmark(id, pos, name)`

Add a mark with the given id (larger than 0), and the given name at the given position. This method can be called at any time before `close()`.

`aifc.tell()`

Return the current write position in the output file. Useful in combination with `setmark()`.

`aifc.writeframes(data)`

Write data to the output file. This method can only be called after the audio file parameters have been set.

*Changed in version 3.4:* Any [bytes-like object](#) is now accepted.

`aifc.writeframesraw(data)`

Like `writeframes()`, except that the header of the audio file is not updated.

*Changed in version 3.4:* Any [bytes-like object](#) is now accepted.

`aifc.close()`

Close the AIFF file. The header of the file is updated to reflect

the actual size of the audio data. After calling this method, the object can no longer be used.

# audioop — Manipulate raw audio data

*Deprecated since version 3.11, will be removed in version 3.13:* The **audioop** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#audioop) [https://peps.python.org/pep-0594/#audioop] for details).

---

The **audioop** module contains some useful operations on sound fragments. It operates on sound fragments consisting of signed integer samples 8, 16, 24 or 32 bits wide, stored in **bytes-like objects**. All scalar items are integers, unless specified otherwise.

*Changed in version 3.4:* Support for 24-bit samples was added. All functions now accept any **bytes-like object**. String input now results in an immediate error.

This module provides support for a-LAW, u-LAW and Intel/DVI ADPCM encodings.

A few of the more complicated operations only take 16-bit samples, otherwise the sample size (in bytes) is always a parameter of the operation.

The module defines the following variables and functions:

*exception* `audioop.error`

This exception is raised on all errors, such as unknown number of bytes per sample, etc.

`audioop.add(fragment1, fragment2, width)`

Return a fragment which is the addition of the two samples passed as parameters. *width* is the sample width in bytes, either 1, 2, 3 or 4. Both fragments should have the same length. Samples are truncated in case of overflow.

`audioop.adpcm2lin(adpcmfragment, width, state)`

Decode an Intel/DVI ADPCM coded fragment to a linear fragment. See the description of `lin2adpcm()` for details on ADPCM coding. Return a tuple (*sample*, *newstate*) where the sample has the width specified in *width*.

`audioop.alaw2lin(fragment, width)`

Convert sound fragments in a-LAW encoding to linearly encoded sound fragments. a-LAW encoding always uses 8 bits samples, so *width* refers only to the sample width of the output fragment here.

`audioop.avg(fragment, width)`

Return the average over all samples in the fragment.

`audioop.avgpp(fragment, width)`

Return the average peak-peak value over all samples in the fragment. No filtering is done, so the usefulness of this routine is questionable.

`audioop.bias(fragment, width, bias)`

Return a fragment that is the original fragment with a bias added to each sample. Samples wrap around in case of overflow.

`audioop.byteswap(fragment, width)`

“Byteswap” all samples in a fragment and returns the modified fragment. Converts big-endian samples to little-endian and vice versa.

*New in version 3.4.*

`audioop.cross(fragment, width)`

Return the number of zero crossings in the fragment passed as an argument.

`audioop.findfactor(fragment, reference)`

Return a factor  $F$  such that `rms(add(fragment, mul(reference, -F)))` is minimal, i.e., return the factor with which you should multiply *reference* to make it match as well as possible to *fragment*. The fragments should both contain 2-byte samples.

The time taken by this routine is proportional to `len(fragment)`.

`audioop.findfit(fragment, reference)`

Try to match *reference* as well as possible to a portion of *fragment* (which should be the longer fragment). This is (conceptually) done by taking slices out of *fragment*, using `findfactor()` to compute the best match, and minimizing the result. The fragments should both contain 2-byte samples. Return a tuple (*offset*, *factor*) where *offset* is the (integer) offset into *fragment* where the optimal match started and *factor* is the (floating-point) factor as per `findfactor()`.

`audioop.findmax(fragment, length)`

Search *fragment* for a slice of length *length* samples (not bytes!) with maximum energy, i.e., return  $i$  for which `rms(fragment[i*2:(i+length)*2])` is maximal. The fragments should both contain 2-byte samples.

The routine takes time proportional to `len(fragment)`.

`audioop.getsample(fragment, width, index)`

Return the value of sample *index* from the fragment.

`audioop.lin2adpcm(fragment, width, state)`

Convert samples to 4 bit Intel/DVI ADPCM encoding. ADPCM coding is an adaptive coding scheme, whereby each 4 bit number is the difference between one sample and the next, divided by a (varying) step. The Intel/DVI ADPCM algorithm has been selected for use by the IMA, so it may well become a

standard.

*state* is a tuple containing the state of the coder. The coder returns a tuple (*adpcmfrag*, *newstate*), and the *newstate* should be passed to the next call of `lin2adpcm()`. In the initial call, `None` can be passed as the state. *adpcmfrag* is the ADPCM coded fragment packed 2 4-bit values per byte.

`audioop.lin2alaw(fragment, width)`

Convert samples in the audio fragment to a-LAW encoding and return this as a bytes object. a-LAW is an audio encoding format whereby you get a dynamic range of about 13 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

`audioop.lin2lin(fragment, width, newwidth)`

Convert samples between 1-, 2-, 3- and 4-byte formats.

### Note

In some audio formats, such as .WAV files, 16, 24 and 32 bit samples are signed, but 8 bit samples are unsigned. So when converting to 8 bit wide samples for these formats, you need to also add 128 to the result:

```
new_frames = audioop.lin2lin(frames, old_width, 1)
new_frames = audioop.bias(new_frames, 1, 128)
```

The same, in reverse, has to be applied when converting from 8 to 16, 24 or 32 bit width samples.

`audioop.lin2ulaw(fragment, width)`

Convert samples in the audio fragment to u-LAW encoding and return this as a bytes object. u-LAW is an audio encoding format whereby you get a dynamic range of about 14 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

`audioop.max(fragment, width)`

Return the maximum of the *absolute value* of all samples in a fragment.

`audioop.maxpp(fragment, width)`

Return the maximum peak-peak value in the sound fragment.

`audioop.minmax(fragment, width)`

Return a tuple consisting of the minimum and maximum values of all samples in the sound fragment.

`audioop.mul(fragment, width, factor)`

Return a fragment that has all samples in the original fragment multiplied by the floating-point value *factor*. Samples are truncated in case of overflow.

`audioop.ratecv(fragment, width, nchannels, inrate, outrate, state[, weightA[, weightB]])`

Convert the frame rate of the input fragment.

*state* is a tuple containing the state of the converter. The converter returns a tuple (*newfragment*, *newstate*), and *newstate* should be passed to the next call of `ratecv()`. The initial call should pass `None` as the state.

The *weightA* and *weightB* arguments are parameters for a simple digital filter and default to 1 and 0 respectively.

`audioop.reverse(fragment, width)`

Reverse the samples in a fragment and returns the modified fragment.

`audioop.rms(fragment, width)`

Return the root-mean-square of the fragment, i.e.  
 $\sqrt{\text{sum}(S_i^2) / n}$ .

This is a measure of the power in an audio signal.

`audioop.tomono(fragment, width, lfactor, rfactor)`

Convert a stereo fragment to a mono fragment. The left channel is multiplied by *lfactor* and the right channel by *rfactor* before adding the two channels to give a mono signal.

`audioop.tostereo(fragment, width, lfactor, rfactor)`

Generate a stereo fragment from a mono fragment. Each pair of samples in the stereo fragment are computed from the mono sample, whereby left channel samples are multiplied by *lfactor* and right channel samples by *rfactor*.

`audioop.ulaw2lin(fragment, width)`

Convert sound fragments in u-LAW encoding to linearly encoded sound fragments. u-LAW encoding always uses 8 bits samples, so *width* refers only to the sample width of the output fragment here.

Note that operations such as `mul()` or `max()` make no distinction between mono and stereo fragments, i.e. all samples are treated equal. If this is a problem the stereo fragment should be split into two mono fragments first and recombined later. Here is an example of how to do that:

```
def mul_stereo(sample, width, lfactor, rfactor):
    lsample = audioop.tomono(sample, width, 1, 0)
    rsample = audioop.tomono(sample, width, 0, 1)
    lsample = audioop.mul(lsample, width, lfactor)
    rsample = audioop.mul(rsample, width, rfactor)
    lsample = audioop.tostereo(lsample, width, 1, 0)
    rsample = audioop.tostereo(rsample, width, 0, 1)
    return audioop.add(lsample, rsample, width)
```

If you use the ADPCM coder to build network packets and you want your protocol to be stateless (i.e. to be able to tolerate packet loss) you should not only transmit the data but also the state. Note that you should send the *initial* state (the one you passed to

`lin2adpcm()` along to the decoder, not the final state (as returned by the coder). If you want to use `struct.Struct` to store the state in binary you can code the first element (the predicted value) in 16 bits and the second (the delta index) in 8.

The ADPCM coders have never been tried against other ADPCM coders, only against themselves. It could well be that I misinterpreted the standards in which case they will not be interoperable with the respective standards.

The `find*` routines might look a bit funny at first sight. They are primarily meant to do echo cancellation. A reasonably fast way to do this is to pick the most energetic piece of the output sample, locate that in the input sample and subtract the whole output sample from the input sample:

```
def echocancel(outputdata, inputdata):
    pos = audioop.findmax(outputdata, 800)      # one tenth
    out_test = outputdata[pos*2:]
    in_test = inputdata[pos*2:]
    ipos, factor = audioop.findfit(in_test, out_test)
    # Optional (for better cancellation):
    # factor = audioop.findfactor(in_test[ipos*2:ipos*2+
    #                               out_test)
    prefill = '\0'*(pos+ipos)*2
    postfill = '\0'*(len(inputdata)-len(prefill)-len(out_test))
    outputdata = prefill + audioop.mul(outputdata, 2, -factor*in_test)
    return audioop.add(inputdata, outputdata, 2)
```

# cgi — Common Gateway Interface support

**Source code:** [Lib/cgi.py](https://github.com/python/cpython/tree/3.12/Lib/cgi.py) [https://github.com/python/cpython/tree/3.12/Lib/cgi.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **cgi** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#cgi) [https://peps.python.org/pep-0594/#cgi] for details and alternatives).

The **FieldStorage** class can typically be replaced with [urllib.parse.parse\\_qs\(\)](https://docs.python.org/3/library/urllib.parse.html#urllib.parse.parse_qs) for GET and HEAD requests, and the [email.message](https://docs.python.org/3/library/email.message.html) module or [multipart](https://pypi.org/project/multipart/) [https://pypi.org/project/multipart/] for POST and PUT. Most [utility functions](#) have replacements.

---

Support module for Common Gateway Interface (CGI) scripts.

This module defines a number of utilities for use by CGI scripts written in Python.

The global variable `maxlen` can be set to an integer indicating the maximum size of a POST request. POST requests larger than this size will result in a [ValueError](#) being raised during parsing. The default value of this variable is `0`, meaning the request size is unlimited.

[Availability](#): not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscrip`ten and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

## Introduction

A CGI script is invoked by an HTTP server, usually to process user input submitted through an HTML `<FORM>` or `<ISINDEX>` element.

Most often, CGI scripts live in the server's special `cgi-bin` directory. The HTTP server places all sorts of information about the request (such as the client's hostname, the requested URL, the query string, and lots of other goodies) in the script's shell environment, executes the script, and sends the script's output back to the client.

The script's input is connected to the client too, and sometimes the form data is read this way; at other times the form data is passed via the "query string" part of the URL. This module is intended to take care of the different cases and provide a simpler interface to the Python script. It also provides a number of utilities that help in debugging scripts, and the latest addition is support for file uploads from a form (if your browser supports it).

The output of a CGI script should consist of two sections, separated by a blank line. The first section contains a number of headers, telling the client what kind of data is following. Python code to generate a minimal header section looks like this:

```
print("Content-Type: text/html")      # HTML is following
print()                              # blank line, end of
```

The second section is usually HTML, which allows the client software to display nicely formatted text with header, in-line images, etc. Here's Python code that prints a simple piece of HTML:

```
print("<TITLE>CGI script output</TITLE>")
print("<H1>This is my first CGI script</H1>")
print("Hello, world!")
```

## Using the `cgi` module

Begin by writing `import cgi`.

When you write a new script, consider adding these lines:

```
import cgitb
cgitb.enable()
```

This activates a special exception handler that will display detailed reports in the web browser if any errors occur. If you'd rather not show the guts of your program to users of your script, you can have the reports saved to files instead, with code like this:

```
import cgitb
cgitb.enable(display=0, logdir="/path/to/logdir")
```

It's very helpful to use this feature during script development. The reports produced by **cgitb** provide information that can save you a lot of time in tracking down bugs. You can always remove the `cgitb` line later when you have tested your script and are confident that it works correctly.

To get at submitted form data, use the **FieldStorage** class. If the form contains non-ASCII characters, use the *encoding* keyword parameter set to the value of the encoding defined for the document. It is usually contained in the META tag in the HEAD section of the HTML document or by the *Content-Type* header. This reads the form contents from the standard input or the environment (depending on the value of various environment variables set according to the CGI standard). Since it may consume standard input, it should be instantiated only once.

The **FieldStorage** instance can be indexed like a Python dictionary. It allows membership testing with the **in** operator, and also supports the standard dictionary method **keys()** and the built-in function **len()**. Form fields containing empty strings are ignored and do not appear in the dictionary; to keep such values, provide a true value for the optional *keep\_blank\_values* keyword parameter when creating the **FieldStorage** instance.

For instance, the following code (which assumes that the *Content-Type* header and blank line have already been printed) checks that the fields `name` and `addr` are both set to a non-empty string:

```
form = cgi.FieldStorage()
if "name" not in form or "addr" not in form:
```

```

print("<H1>Error</H1>")
print("Please fill in the name and addr fields.")
return
print("<p>name:", form["name"].value)
print("<p>addr:", form["addr"].value)
...further form processing here...

```

Here the fields, accessed through `form[key]`, are themselves instances of **FieldStorage** (or **MiniFieldStorage**, depending on the form encoding). The **value** attribute of the instance yields the string value of the field. The **getvalue()** method returns this string value directly; it also accepts an optional second argument as a default to return if the requested key is not present.

If the submitted form data contains more than one field with the same name, the object retrieved by `form[key]` is not a **FieldStorage** or **MiniFieldStorage** instance but a list of such instances. Similarly, in this situation, `form.getvalue(key)` would return a list of strings. If you expect this possibility (when your HTML form contains multiple fields with the same name), use the **getlist()** method, which always returns a list of values (so that you do not need to special-case the single item case). For example, this code concatenates any number of username fields, separated by commas:

```

value = form.getlist("username")
usernames = ",".join(value)

```

If a field represents an uploaded file, accessing the value via the **value** attribute or the **getvalue()** method reads the entire file in memory as bytes. This may not be what you want. You can test for an uploaded file by testing either the **filename** attribute or the **file** attribute. You can then read the data from the **file** attribute before it is automatically closed as part of the garbage collection of the **FieldStorage** instance (the **read()** and **readline()** methods will return bytes):

```

fileitem = form["userfile"]
if fileitem.file:
    # It's an uploaded file; count lines

```

```
linecount = 0
while True:
    line = fileitem.file.readline()
    if not line: break
    linecount = linecount + 1
```

**FieldStorage** objects also support being used in a **with** statement, which will automatically close them when done.

If an error is encountered when obtaining the contents of an uploaded file (for example, when the user interrupts the form submission by clicking on a Back or Cancel button) the **done** attribute of the object for the field will be set to the value -1.

The file upload draft standard entertains the possibility of uploading multiple files from one field (using a recursive *multipart/\** encoding). When this occurs, the item will be a dictionary-like **FieldStorage** item. This can be determined by testing its **type** attribute, which should be *multipart/form-data* (or perhaps another MIME type matching *multipart/\**). In this case, it can be iterated over recursively just like the top-level form object.

When a form is submitted in the “old” format (as the query string or as a single data part of type *application/x-www-form-urlencoded*), the items will actually be instances of the class **MiniFieldStorage**. In this case, the **list**, **file**, and **filename** attributes are always **None**.

A form submitted via POST that also has a query string will contain both **FieldStorage** and **MiniFieldStorage** items.

*Changed in version 3.4:* The **file** attribute is automatically closed upon the garbage collection of the creating **FieldStorage** instance.

*Changed in version 3.5:* Added support for the context management protocol to the **FieldStorage** class.

## Higher Level Interface

The previous section explains how to read CGI form data using the **FieldStorage** class. This section describes a higher level interface which was added to this class to allow one to do it in a more readable and intuitive way. The interface doesn't make the techniques described in previous sections obsolete — they are still useful to process file uploads efficiently, for example.

The interface consists of two simple methods. Using the methods you can process form data in a generic way, without the need to worry whether only one or more values were posted under one name.

In the previous section, you learned to write following code anytime you expected a user to post more than one value under one name:

```
item = form.getvalue("item")
if isinstance(item, list):
    # The user is requesting more than one item.
else:
    # The user is requesting only one item.
```

This situation is common for example when a form contains a group of multiple checkboxes with the same name:

```
<input type="checkbox" name="item" value="1" />
<input type="checkbox" name="item" value="2" />
```

In most situations, however, there's only one form control with a particular name in a form and then you expect and need only one value associated with this name. So you write a script containing for example this code:

```
user = form.getvalue("user").upper()
```

The problem with the code is that you should never expect that a client will provide valid input to your scripts. For example, if a curious user appends another `user=foo` pair to the query string, then the script would crash, because in this situation the `getvalue("user")` method call returns a list instead of a string. Calling the `upper()` method on a list is not valid (since lists do

not have a method of this name) and results in an `AttributeError` exception.

Therefore, the appropriate way to read form data values was to always use the code which checks whether the obtained value is a single value or a list of values. That's annoying and leads to less readable scripts.

A more convenient approach is to use the methods `getfirst()` and `getlist()` provided by this higher level interface.

`FieldStorage.getfirst(name, default=None)`

This method always returns only one value associated with form field *name*. The method returns only the first value in case that more values were posted under such name. Please note that the order in which the values are received may vary from browser to browser and should not be counted on. <sup>1</sup> If no such form field or value exists then the method returns the value specified by the optional parameter *default*. This parameter defaults to `None` if not specified.

`FieldStorage.getlist(name)`

This method always returns a list of values associated with form field *name*. The method returns an empty list if no such form field or value exists for *name*. It returns a list consisting of one item if only one such value exists.

Using these methods you can write nice compact code:

```
import cgi
form = cgi.FieldStorage()
user = form.getfirst("user", "").upper()      # This way i
for item in form.getlist("item"):
    do_something(item)
```

## Functions

These are useful if you want more control, or if you want to employ some of the algorithms implemented in this module in other

circumstances.

```
cgi.parse(fp=None, environ=os.environ, keep_blank_values=False,
strict_parsing=False, separator='&')
```

Parse a query in the environment or from a file (the file defaults to `sys.stdin`). The `keep_blank_values`, `strict_parsing` and `separator` parameters are passed to `urllib.parse.parse_qs()` unchanged.

*Deprecated since version 3.11, will be removed in version 3.13:*  
This function, like the rest of the `cgi` module, is deprecated. It can be replaced by calling `urllib.parse.parse_qs()` directly on the desired query string (except for `multipart/form-data` input, which can be handled as described for `parse_multipart()`).

```
cgi.parse_multipart(fp, pdict, encoding='utf-8', errors='replace',
separator='&')
```

Parse input of type *multipart/form-data* (for file uploads). Arguments are `fp` for the input file, `pdict` for a dictionary containing other parameters in the *Content-Type* header, and `encoding`, the request encoding.

Returns a dictionary just like `urllib.parse.parse_qs()`: keys are the field names, each value is a list of values for that field. For non-file fields, the value is a list of strings.

This is easy to use but not much good if you are expecting megabytes to be uploaded — in that case, use the **FieldStorage** class instead which is much more flexible.

*Changed in version 3.7:* Added the `encoding` and `errors` parameters. For non-file fields, the value is now a list of strings, not bytes.

*Changed in version 3.10:* Added the `separator` parameter.

*Deprecated since version 3.11, will be removed in version 3.13:*  
This function, like the rest of the `cgi` module, is deprecated. It can be replaced with the functionality in the `email`

package (e.g. `email.message.EmailMessage/`  
`email.message.Message`) which implements the same  
MIME RFCs, or with the `multipart` [[https://pypi.org/project/](https://pypi.org/project/multipart/)  
`multipart/`] PyPI project.

### `cgi.parse_header(string)`

Parse a MIME header (such as *Content-Type*) into a main value  
and a dictionary of parameters.

*Deprecated since version 3.11, will be removed in version 3.13:*  
This function, like the rest of the `cgi` module, is deprecated.  
It can be replaced with the functionality in the `email`  
package, which implements the same MIME RFCs.

For example, with `email.message.EmailMessage`:

```
from email.message import EmailMessage
msg = EmailMessage()
msg['content-type'] = 'application/json; charset="u
main, params = msg.get_content_type(), msg['content
```

### `cgi.test()`

Robust test CGI script, usable as main program. Writes  
minimal HTTP headers and formats all information provided  
to the script in HTML format.

### `cgi.print_enviro()`

Format the shell environment in HTML.

### `cgi.print_form(form)`

Format a form in HTML.

### `cgi.print_directory()`

Format the current directory in HTML.

### `cgi.print_enviro_usage()`

Print a list of useful (used by CGI) environment variables in

HTML.

## Caring about security

There's one important rule: if you invoke an external program (via `os.system()`, `os.popen()` or other functions with similar functionality), make very sure you don't pass arbitrary strings received from the client to the shell. This is a well-known security hole whereby clever hackers anywhere on the web can exploit a gullible CGI script to invoke arbitrary shell commands. Even parts of the URL or field names cannot be trusted, since the request doesn't have to come from your form!

To be on the safe side, if you must pass a string gotten from a form to a shell command, you should make sure the string contains only alphanumeric characters, dashes, underscores, and periods.

## Installing your CGI script on a Unix system

Read the documentation for your HTTP server and check with your local system administrator to find the directory where CGI scripts should be installed; usually this is in a directory `cgi-bin` in the server tree.

Make sure that your script is readable and executable by “others”; the Unix file mode should be `00755` octal (use `chmod 0755 filename`). Make sure that the first line of the script contains `#!/` starting in column 1 followed by the pathname of the Python interpreter, for instance:

```
#!/usr/local/bin/python
```

Make sure the Python interpreter exists and is executable by “others”.

Make sure that any files your script needs to read or write are readable or writable, respectively, by “others” — their mode should be `00644` for readable and `00666` for writable. This is because,

for security reasons, the HTTP server executes your script as user “nobody”, without any special privileges. It can only read (write, execute) files that everybody can read (write, execute). The current directory at execution time is also different (it is usually the server’s cgi-bin directory) and the set of environment variables is also different from what you get when you log in. In particular, don’t count on the shell’s search path for executables (**PATH**) or the Python module search path (**PYTHONPATH**) to be set to anything interesting.

If you need to load modules from a directory which is not on Python’s default module search path, you can change the path in your script, before importing other modules. For example:

```
import sys
sys.path.insert(0, "/usr/home/joe/lib/python")
sys.path.insert(0, "/usr/local/lib/python")
```

(This way, the directory inserted last will be searched first!)

Instructions for non-Unix systems will vary; check your HTTP server’s documentation (it will usually have a section on CGI scripts).

## Testing your CGI script

Unfortunately, a CGI script will generally not run when you try it from the command line, and a script that works perfectly from the command line may fail mysteriously when run from the server. There’s one reason why you should still test your script from the command line: if it contains a syntax error, the Python interpreter won’t execute it at all, and the HTTP server will most likely send a cryptic error to the client.

Assuming your script has no syntax errors, yet it does not work, you have no choice but to read the next section.

## Debugging CGI scripts

First of all, check for trivial installation errors — reading the section

above on installing your CGI script carefully can save you a lot of time. If you wonder whether you have understood the installation procedure correctly, try installing a copy of this module file (`cgi.py`) as a CGI script. When invoked as a script, the file will dump its environment and the contents of the form in HTML format. Give it the right mode etc., and send it a request. If it's installed in the standard `cgi-bin` directory, it should be possible to send it a request by entering a URL into your browser of the form:

```
http://yourhostname/cgi-bin/cgi.py?name=Joe+Blow&addr=At
```

If this gives an error of type 404, the server cannot find the script – perhaps you need to install it in a different directory. If it gives another error, there's an installation problem that you should fix before trying to go any further. If you get a nicely formatted listing of the environment and form content (in this example, the fields should be listed as “addr” with value “At Home” and “name” with value “Joe Blow”), the `cgi.py` script has been installed correctly. If you follow the same procedure for your own script, you should now be able to debug it.

The next step could be to call the `cgi` module's `test()` function from your script: replace its main code with the single statement

```
cgi.test()
```

This should produce the same results as those gotten from installing the `cgi.py` file itself.

When an ordinary Python script raises an unhandled exception (for whatever reason: of a typo in a module name, a file that can't be opened, etc.), the Python interpreter prints a nice traceback and exits. While the Python interpreter will still do this when your CGI script raises an exception, most likely the traceback will end up in one of the HTTP server's log files, or be discarded altogether.

Fortunately, once you have managed to get your script to execute *some* code, you can easily send tracebacks to the web browser using the `cgitb` module. If you haven't done so already, just add the lines:

```
import cgitb
cgitb.enable()
```

to the top of your script. Then try running it again; when a problem occurs, you should see a detailed report that will likely make apparent the cause of the crash.

If you suspect that there may be a problem in importing the `cgitb` module, you can use an even more robust approach (which only uses built-in modules):

```
import sys
sys.stderr = sys.stdout
print("Content-Type: text/plain")
print()
...your code here...
```

This relies on the Python interpreter to print the traceback. The content type of the output is set to plain text, which disables all HTML processing. If your script works, the raw HTML will be displayed by your client. If it raises an exception, most likely after the first two lines have been printed, a traceback will be displayed. Because no HTML interpretation is going on, the traceback will be readable.

## Common problems and solutions

- Most HTTP servers buffer the output from CGI scripts until the script is completed. This means that it is not possible to display a progress report on the client's display while the script is running.
- Check the installation instructions above.
- Check the HTTP server's log files. (`tail -f logfile` in a separate window may be useful!)
- Always check a script for syntax errors first, by doing something like `python script.py`.
- If your script does not have any syntax errors, try adding `import cgitb; cgitb.enable()` to the top of the script.
- When invoking external programs, make sure they can be found. Usually, this means using absolute path names —

**PATH** is usually not set to a very useful value in a CGI script.

- When reading or writing external files, make sure they can be read or written by the userid under which your CGI script will be running: this is typically the userid under which the web server is running, or some explicitly specified userid for a web server's `suidexec` feature.
- Don't try to give a CGI script a set-uid mode. This doesn't work on most systems, and is a security liability as well.

## Footnotes

1

Note that some recent versions of the HTML specification do state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.

# **cgitb** — Traceback manager for CGI scripts

**Source code:** [Lib/cgitb.py](https://github.com/python/cpython/tree/3.12/Lib/cgitb.py) [https://github.com/python/cpython/tree/3.12/Lib/cgitb.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **cgitb** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#cgitb) [https://peps.python.org/pep-0594/#cgitb] for details).

---

The **cgitb** module provides a special exception handler for Python scripts. (Its name is a bit misleading. It was originally designed to display extensive traceback information in HTML for CGI scripts. It was later generalized to also display this information in plain text.) After this module is activated, if an uncaught exception occurs, a detailed, formatted report will be displayed. The report includes a traceback showing excerpts of the source code for each level, as well as the values of the arguments and local variables to currently running functions, to help you debug the problem. Optionally, you can save this information to a file instead of sending it to the browser.

To enable this feature, simply add this to the top of your CGI script:

```
import cgitb
cgitb.enable()
```

The options to the **enable()** function control whether the report is displayed in the browser and whether the report is logged to a file for later analysis.

```
cgitb.enable(display=1, logdir=None, context=5, format='html')
```

This function causes the **cgitb** module to take over the interpreter's default handling for exceptions by setting the value of **sys.excepthook**.

The optional argument *display* defaults to 1 and can be set to 0 to suppress sending the traceback to the browser. If the argument *logdir* is present, the traceback reports are written to files. The value of *logdir* should be a directory where these files will be placed. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5. If the optional argument *format* is "html", the output is formatted as HTML. Any other value forces plain text output. The default value is "html".

`cgibt.text(info, context=5)`

This function handles the exception described by *info* (a 3-tuple containing the result of `sys.exc_info()`), formatting its traceback as text and returning the result as a string. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5.

`cgibt.html(info, context=5)`

This function handles the exception described by *info* (a 3-tuple containing the result of `sys.exc_info()`), formatting its traceback as HTML and returning the result as a string. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5.

`cgibt.handler(info=None)`

This function handles an exception using the default settings (that is, show a report in the browser, but don't log to a file). This can be used when you've caught an exception and want to report it using `cgibt`. The optional *info* argument should be a 3-tuple containing an exception type, exception value, and traceback object, exactly like the tuple returned by `sys.exc_info()`. If the *info* argument is not supplied, the current exception is obtained from `sys.exc_info()`.

# chunk — Read IFF chunked data

**Source code:** [Lib/chunk.py](#) [<https://github.com/python/cpython/tree/3.12/Lib/chunk.py>]

*Deprecated since version 3.11, will be removed in version 3.13:* The **chunk** module is deprecated (see [PEP 594](#) [<https://peps.python.org/pep-0594/#chunk>] for details).

---

This module provides an interface for reading files that use EA IFF 85 chunks. [1](#) This format is used in at least the Audio Interchange File Format (AIFF/AIFF-C) and the Real Media File Format (RMFF). The WAVE audio file format is closely related and can also be read using this module.

A chunk has the following structure:

Offset
Chunk ID
Size of chunk in big-endian byte order, not including the header
Data bytes, where $n$ is the size given in the preceding field
Pad byte needed if $n$ is odd and chunk alignment is used

The ID is a 4-byte string which identifies the type of chunk.

The size field (a 32-bit value, encoded using big-endian byte order) gives the size of the chunk data, not including the 8-byte header.

Usually an IFF-type file consists of one or more chunks. The proposed usage of the **Chunk** class defined here is to instantiate an instance at the start of each chunk and read from the instance until it reaches the end, after which a new instance can be instantiated. At the end of the file, creating a new instance will fail with an **EOFError** exception.

```
class chunk.Chunk(file, align = True, bigendian = True,
incheader = False)
```

Class which represents a chunk. The *file* argument is expected to be a file-like object. An instance of this class is specifically allowed. The only method that is needed is `read()`. If the methods `seek()` and `tell()` are present and don't raise an exception, they are also used. If these methods are present and raise an exception, they are expected to not have altered the object. If the optional argument *align* is true, chunks are assumed to be aligned on 2-byte boundaries. If *align* is false, no alignment is assumed. The default value is true. If the optional argument *bigendian* is false, the chunk size is assumed to be in little-endian order. This is needed for WAVE audio files. The default value is true. If the optional argument *incheader* is true, the size given in the chunk header includes the size of the header. The default value is false.

A **Chunk** object supports the following methods:

`getname()`

Returns the name (ID) of the chunk. This is the first 4 bytes of the chunk.

`getsize()`

Returns the size of the chunk.

`close()`

Close and skip to the end of the chunk. This does not close the underlying file.

The remaining methods will raise **OSError** if called after the `close()` method has been called. Before Python 3.3, they used to raise **IOError**, now an alias of **OSError**.

`isatty()`

Returns `False`.

`seek(pos, whence = 0)`

Set the chunk's current position. The *whence* argument is optional and defaults to 0 (absolute file positioning); other values are 1 (seek relative to the current position) and 2 (seek relative to the file's end). There is no return value. If the underlying file does not allow seek, only forward seeks are allowed.

`tell()`

Return the current position into the chunk.

`read(size = - 1)`

Read at most *size* bytes from the chunk (less if the read hits the end of the chunk before obtaining *size* bytes). If the *size* argument is negative or omitted, read all data until the end of the chunk. An empty bytes object is returned when the end of the chunk is encountered immediately.

`skip()`

Skip to the end of the chunk. All further calls to `read()` for the chunk will return `b''`. If you are not interested in the contents of the chunk, this method should be called so that the file points to the start of the next chunk.

## Footnotes

# crypt — Function to check Unix passwords

**Source code:** [Lib/crypt.py](https://github.com/python/cpython/tree/3.12/Lib/crypt.py) [https://github.com/python/cpython/tree/3.12/Lib/crypt.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **crypt** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#crypt) [https://peps.python.org/pep-0594/#crypt] for details and alternatives). The **hashlib** module is a potential replacement for certain use cases. The [passlib](https://pypi.org/project/passlib/) [https://pypi.org/project/passlib/] package can replace all use cases of this module.

---

This module implements an interface to the **crypt(3)** routine, which is a one-way hash function based upon a modified DES algorithm; see the Unix man page for further details. Possible uses include storing hashed passwords so you can check passwords without storing the actual password, or attempting to crack Unix passwords with a dictionary.

Notice that the behavior of this module depends on the actual implementation of the **crypt(3)** routine in the running system. Therefore, any extensions available on the current implementation will also be available on this module.

**Availability:** Unix, not VxWorks.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

## Hashing Methods

*New in version 3.3.*

The `crypt` module defines the list of hashing methods (not all methods are available on all platforms):

`crypt.METHOD_SHA512`

A Modular Crypt Format method with 16 character salt and 86 character hash based on the SHA-512 hash function. This is the strongest method.

`crypt.METHOD_SHA256`

Another Modular Crypt Format method with 16 character salt and 43 character hash based on the SHA-256 hash function.

`crypt.METHOD_BLOWFISH`

Another Modular Crypt Format method with 22 character salt and 31 character hash based on the Blowfish cipher.

*New in version 3.7.*

`crypt.METHOD_MD5`

Another Modular Crypt Format method with 8 character salt and 22 character hash based on the MD5 hash function.

`crypt.METHOD_CRYPT`

The traditional method with a 2 character salt and 13 characters of hash. This is the weakest method.

## Module Attributes

*New in version 3.3.*

`crypt.methods`

A list of available password hashing algorithms, as `crypt.METHOD_*` objects. This list is sorted from strongest to weakest.

# Module Functions

The `crypt` module defines the following functions:

`crypt.crypt(word, salt = None)`

*word* will usually be a user's password as typed at a prompt or in a graphical interface. The optional *salt* is either a string as returned from `mksalt()`, one of the `crypt.METHOD_*` values (though not all may be available on all platforms), or a full encrypted password including salt, as returned by this function. If *salt* is not provided, the strongest method available in `methods` will be used.

Checking a password is usually done by passing the plain-text password as *word* and the full results of a previous `crypt()` call, which should be the same as the results of this call.

*salt* (either a random 2 or 16 character string, possibly prefixed with `$digit$` to indicate the method) which will be used to perturb the encryption algorithm. The characters in *salt* must be in the set `[./a-zA-Z0-9]`, with the exception of Modular Crypt Format which prefixes a `$digit$`.

Returns the hashed password as a string, which will be composed of characters from the same alphabet as the salt.

Since a few `crypt(3)` extensions allow different values, with different sizes in the *salt*, it is recommended to use the full encrypted password as salt when checking for a password.

*Changed in version 3.3:* Accept `crypt.METHOD_*` values in addition to strings for *salt*.

`crypt.mksalt(method = None, *, rounds = None)`

Return a randomly generated salt of the specified method. If no *method* is given, the strongest method available in `methods` is used.

The return value is a string suitable for passing as the *salt*

argument to `crypt()`.

*rounds* specifies the number of rounds for `METHOD_SHA256`, `METHOD_SHA512` and `METHOD_BLOWFISH`. For `METHOD_SHA256` and `METHOD_SHA512` it must be an integer between 1000 and 999\_999\_999, the default is 5000. For `METHOD_BLOWFISH` it must be a power of two between 16 ( $2^4$ ) and 2\_147\_483\_648 ( $2^{31}$ ), the default is 4096 ( $2^{12}$ ).

*New in version 3.3.*

*Changed in version 3.7:* Added the *rounds* parameter.

## Examples

A simple example illustrating typical use (a constant-time comparison operation is needed to limit exposure to timing attacks. `hmac.compare_digest()` is suitable for this purpose):

```
import pwd
import crypt
import getpass
from hmac import compare_digest as compare_hash

def login():
    username = input('Python login: ')
    cryptedpasswd = pwd.getpwnam(username)[1]
    if cryptedpasswd:
        if cryptedpasswd == 'x' or cryptedpasswd == '*':
            raise ValueError('no support for shadow pass')
        cleartext = getpass.getpass()
        return compare_hash(crypt.crypt(cleartext, crypt
    else:
        return True
```

To generate a hash of a password using the strongest available method and check it against the original:

```
import crypt
from hmac import compare_digest as compare_hash
```

```
hashed = crypt.crypt(plaintext)
if not compare_hash(hashed, crypt.crypt(plaintext, hashed)):
    raise ValueError("hashed version doesn't validate against original")
```

# imghdr — Determine the type of an image

**Source code:** [Lib/imghdr.py](https://github.com/python/cpython/tree/3.12/Lib/imghdr.py) [https://github.com/python/cpython/tree/3.12/Lib/imghdr.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The [imghdr](#) module is deprecated (see [PEP 594](#) [https://peps.python.org/pep-0594/#imghdr] for details and alternatives).

---

The [imghdr](#) module determines the type of image contained in a file or byte stream.

The [imghdr](#) module defines the following function:

`imghdr.what(file, h=None)`

Test the image data contained in the file named *file* and return a string describing the image type. If *h* is provided, the *file* argument is ignored and *h* is assumed to contain the byte stream to test.

*Changed in version 3.6:* Accepts a [path-like object](#).

The following image types are recognized, as listed below with the return value from `what()`:

**Image format**

SGI ImageLib Files

GIF 87a and 89a Files

Portable Bitmap Files

Portable Graymap Files

Portable Pixmap Files

TIFF Files

Sun Raster Files

X-Bitmap Files

JPEG data in JFIF or Exif formats

BMP files

Portable Network Graphics

Webp files

OpenEXR Files

*New in version 3.5:* The *exr* and *webp* formats were added.

You can extend the list of file types `imghdr` can recognize by appending to this variable:

`imghdr.tests`

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When `what()` is called with a byte-stream, the file-like object will be `None`.

The test function should return a string describing the image type if the test succeeded, or `None` if it failed.

Example:

```
>>> import imghdr
>>> imghdr.what('bass.gif')
'gif'
```

# mailcap — Mailcap file handling

**Source code:** [Lib/mailcap.py](https://github.com/python/cpython/tree/3.12/Lib/mailcap.py) [https://github.com/python/cpython/tree/3.12/Lib/mailcap.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **mailcap** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#mailcap) [https://peps.python.org/pep-0594/#mailcap] for details). The **mimetypes** module provides an alternative.

---

Mailcap files are used to configure how MIME-aware applications such as mail readers and web browsers react to files with different MIME types. (The name “mailcap” is derived from the phrase “mail capability”.) For example, a mailcap file might contain a line like `video/mpeg; xmpeg %s`. Then, if the user encounters an email message or web document with the MIME type `video/mpeg`, `%s` will be replaced by a filename (usually one belonging to a temporary file) and the **xmpeg** program can be automatically started to view the file.

The mailcap format is documented in [RFC 1524](https://datatracker.ietf.org/doc/html/rfc1524.html) [https://datatracker.ietf.org/doc/html/rfc1524.html], “A User Agent Configuration Mechanism For Multimedia Mail Format Information”, but is not an internet standard. However, mailcap files are supported on most Unix systems.

```
mailcap.findmatch(caps, MIMEtype, key='view', filename='/dev/null', plist=[])
```

Return a 2-tuple; the first element is a string containing the command line to be executed (which can be passed to `os.system()`), and the second element is the mailcap entry for a given MIME type. If no matching MIME type can be found, `(None, None)` is returned.

*key* is the name of the field desired, which represents the type of activity to be performed; the default value is 'view', since in the most common case you simply want to view the body of the MIME-typed data. Other possible values might be 'compose' and 'edit', if you wanted to create a new body of the given MIME type or alter the existing body data. See [RFC 1524](https://datatracker.ietf.org/doc/html/rfc1524.html) [https://datatracker.ietf.org/doc/html/rfc1524.html] for a complete list of these fields.

*filename* is the filename to be substituted for %s in the command line; the default value is '/dev/null' which is almost certainly not what you want, so usually you'll override it by specifying a filename.

*plist* can be a list containing named parameters; the default value is simply an empty list. Each entry in the list must be a string containing the parameter name, an equals sign ('='), and the parameter's value. Mailcap entries can contain named parameters like %{foo}, which will be replaced by the value of the parameter named 'foo'. For example, if the command line `showpartial %{id} %{number} %{total}` was in a mailcap file, and *plist* was set to `['id=1', 'number=2', 'total=3']`, the resulting command line would be `'showpartial 1 2 3'`.

In a mailcap file, the "test" field can optionally be specified to test some external condition (such as the machine architecture, or the window system in use) to determine whether or not the mailcap line applies. `findmatch()` will automatically check such conditions and skip the entry if the check fails.

*Changed in version 3.11:* To prevent security issues with shell metacharacters (symbols that have special effects in a shell command line), `findmatch` will refuse to inject ASCII characters other than alphanumerics and `@+=:./-_` into the returned command line.

If a disallowed character appears in *filename*, `findmatch` will always return `(None, None)` as if no entry was found. If such a character appears elsewhere (a value in *plist* or in

*MIMEtype*), `findmatch` will ignore all mailcap entries which use that value. A **warning** will be raised in either case.

### `mailcap.getcaps()`

Returns a dictionary mapping MIME types to a list of mailcap file entries. This dictionary must be passed to the `findmatch()` function. An entry is stored as a list of dictionaries, but it shouldn't be necessary to know the details of this representation.

The information is derived from all of the mailcap files found on the system. Settings in the user's mailcap file `$HOME/.mailcap` will override settings in the system mailcap files `/etc/mailcap`, `/usr/etc/mailcap`, and `/usr/local/etc/mailcap`.

### An example usage:

```
>>> import mailcap
>>> d = mailcap.getcaps()
>>> mailcap.findmatch(d, 'video/mpeg', filename='tmp1223',
('xmpeg tmp1223', {'view': 'xmpeg %s'}))
```

# msilib — Read and write Microsoft Installer files

**Source code:** [Lib/msilib/\\_init\\_.py](https://github.com/python/cpython/tree/3.12/Lib/msilib/_init_.py) [https://github.com/python/cpython/tree/3.12/Lib/msilib/\_init\_.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **msilib** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#msilib) [https://peps.python.org/pep-0594/#msilib] for details).

---

The **msilib** supports the creation of Microsoft Installer (`.msi`) files. Because these files often contain an embedded “cabinet” file (`.cab`), it also exposes an API to create CAB files. Support for reading `.cab` files is currently not implemented; read support for the `.msi` database is possible.

This package aims to provide complete access to all tables in an `.msi` file, therefore, it is a fairly low-level API. One primary application of this package is the creation of Python installer package itself (although that currently uses a different version of `msilib`).

The package contents can be roughly split into four parts: low-level CAB routines, low-level MSI routines, higher-level MSI routines, and standard table structures.

`msilib.FCICreate(cabname, files)`

Create a new CAB file named *cabname*. *files* must be a list of tuples, each containing the name of the file on disk, and the name of the file inside the CAB file.

The files are added to the CAB file in the order they appear in the list. All files are added into a single CAB file, using the MSZIP compression algorithm.

Callbacks to Python for the various steps of MSI creation are currently not exposed.

`msilib.UuidCreate()`

Return the string representation of a new unique identifier. This wraps the Windows API functions **UuidCreate()** and **UuidToString()**.

`msilib.OpenDatabase(path, persist)`

Return a new database object by calling `MsiOpenDatabase`. *path* is the file name of the MSI file; *persist* can be one of the constants `MSIDBOPEN_CREATEDIRECT`, `MSIDBOPEN_CREATE`, `MSIDBOPEN_DIRECT`, `MSIDBOPEN_READONLY`, or `MSIDBOPEN_TRANSACT`, and may include the flag `MSIDBOPEN_PATCHFILE`. See the Microsoft documentation for the meaning of these flags; depending on the flags, an existing database is opened, or a new one created.

`msilib.CreateRecord(count)`

Return a new record object by calling **MSICreateRecord()**. *count* is the number of fields of the record.

`msilib.init_database(name, schema, ProductName, ProductCode, ProductVersion, Manufacturer)`

Create and return a new database *name*, initialize it with *schema*, and set the properties *ProductName*, *ProductCode*, *ProductVersion*, and *Manufacturer*.

*schema* must be a module object containing `tables` and `_Validation_records` attributes; typically, **`msilib.schema`** should be used.

The database will contain just the schema and the validation records when this function returns.

`msilib.add_data(database, table, records)`

Add all *records* to the table named *table* in *database*.

The *table* argument must be one of the predefined tables in the MSI schema, e.g. 'Feature', 'File', 'Component', 'Dialog', 'Control', etc.

*records* should be a list of tuples, each one containing all fields of a record according to the schema of the table. For optional fields, `None` can be passed.

Field values can be ints, strings, or instances of the Binary class.

`class msilib.Binary(filename)`

Represents entries in the Binary table; inserting such an object using `add_data()` reads the file named *filename* into the table.

`msilib.add_tables(database, module)`

Add all table content from *module* to *database*. *module* must contain an attribute *tables* listing all tables for which content should be added, and one attribute per table that has the actual content.

This is typically used to install the sequence tables.

`msilib.add_stream(database, name, path)`

Add the file *path* into the `_Stream` table of *database*, with the stream name *name*.

`msilib.gen_uuid()`

Return a new UUID, in the format that MSI typically requires (i.e. in curly braces, and with all hexdigits in uppercase).

## Database Objects

### Database.OpenView(*sql*)

Return a view object, by calling **MSIDatabaseOpenView()**.  
*sql* is the SQL statement to execute.

### Database.Commit()

Commit the changes pending in the current transaction, by calling **MSIDatabaseCommit()**.

### Database.GetSummaryInformation(*count*)

Return a new summary information object, by calling **MsiGetSummaryInformation()**. *count* is the maximum number of updated values.

### Database.Close()

Close the database object, through **MsiCloseHandle()**.

*New in version 3.7.*

### See also

## View Objects

## View.Execute(*params*)

Execute the SQL query of the view, through **MSIViewExecute()**. If *params* is not `None`, it is a record describing actual values of the parameter tokens in the query.

## View.GetColumnInfo(*kind*)

Return a record describing the columns of the view, through calling **MsiViewGetColumnInfo()**. *kind* can be either `MSICOLINFO_NAMES` or `MSICOLINFO_TYPES`.

## View.Fetch()

Return a result record of the query, through calling **MsiViewFetch()**.

## View.Modify(*kind*, *data*)

Modify the view, by calling **MsiViewModify()**. *kind* can be one of `MSIMODIFY_SEEK`, `MSIMODIFY_REFRESH`, `MSIMODIFY_INSERT`, `MSIMODIFY_UPDATE`, `MSIMODIFY_ASSIGN`, `MSIMODIFY_REPLACE`, `MSIMODIFY_MERGE`, `MSIMODIFY_DELETE`, `MSIMODIFY_INSERT_TEMPORARY`, `MSIMODIFY_VALIDATE`, `MSIMODIFY_VALIDATE_NEW`, `MSIMODIFY_VALIDATE_FIELD`, or `MSIMODIFY_VALIDATE_DELETE`.

*data* must be a record describing the new data.

## View.Close()

Close the view, through **MsiViewClose()**.

## Summary Information Objects

### SummaryInformation.GetProperty(*field*)

Return a property of the summary, through **MsiSummaryInfoGetProperty()**. *field* is the name of the property, and can be one of the constants `PID_CODEPAGE`, `PID_TITLE`, `PID_SUBJECT`, `PID_AUTHOR`, `PID_KEYWORDS`, `PID_COMMENTS`, `PID_TEMPLATE`, `PID_LASTAUTHOR`, `PID_REVNUMBER`, `PID_LASTPRINTED`, `PID_CREATE_DTM`, `PID_LASTSAVE_DTM`, `PID_PAGECOUNT`, `PID_WORDCOUNT`, `PID_CHARCOUNT`, `PID_APPNAME`, or `PID_SECURITY`.

### SummaryInformation.GetPropertyCount()

Return the number of summary properties, through **MsiSummaryInfoGetPropertyCount()**.

### SummaryInformation.SetProperty(*field*, *value*)

Set a property through **MsiSummaryInfoSetProperty()**. *field* can have the same values as in [GetProperty\(\)](#), *value* is the new value of the property. Possible value types are integer and string.

### SummaryInformation.Persist()

Write the modified properties to the summary information stream, using **MsiSummaryInfoPersist()**.

### See also

[MsiSummaryInfoGetProperty](https://msdn.microsoft.com/en-us/library/windows/desktop/aa370409.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370409.aspx] [MsiSummaryInfoGetPropertyCount](https://msdn.microsoft.com/en-us/library/windows/desktop/aa370488.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370488.aspx] [MsiSummaryInfoSetProperty](https://msdn.microsoft.com/en-us/library/windows/desktop/aa370488.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370488.aspx]

## Record Objects

`Record.GetFieldCount()`

Return the number of fields of the record, through **`MsiRecordGetFieldCount()`**.

`Record.GetInteger(field)`

Return the value of *field* as an integer where possible. *field* must be an integer.

`Record.GetString(field)`

Return the value of *field* as a string where possible. *field* must be an integer.

`Record.SetString(field, value)`

Set *field* to *value* through **`MsiRecordSetString()`**. *field* must be an integer; *value* a string.

`Record.SetStream(field, value)`

Set *field* to the contents of the file named *value*, through **`MsiRecordSetStream()`**. *field* must be an integer; *value* a string.

`Record.SetInteger(field, value)`

Set *field* to *value* through **`MsiRecordSetInteger()`**. Both *field* and *value* must be an integer.

`Record.ClearData()`

Set all fields of the record to 0, through **`MsiRecordClearData()`**.

**See also**

[MsiRecordGetFieldCount](https://msdn.microsoft.com/en-us/library/windows/desktop/aa370366.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370366.aspx] [MsiRecordSetString](https://msdn.microsoft.com/en-us/library/windows/desktop/aa370373.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370373.aspx] [MsiRecordSetStream](https://msdn.microsoft.com/en-us/library/windows/desktop/aa370372.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370372.aspx] [MsiRecordSetInteger](https://msdn.microsoft.com/en-us/library/windows/desktop/aa370371.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370371.aspx] [MsiRecordClearData](https://msdn.microsoft.com/en-us/library/windows/desktop/aa370364.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370364.aspx]

## Errors

All wrappers around MSI functions raise **MSIError**; the string inside the exception will contain more detail.

## CAB Objects

*class* msilib.CAB(*name*)

The class **CAB** represents a CAB file. During MSI construction, files will be added simultaneously to the `Files` table, and to a CAB file. Then, when all files have been added, the CAB file can be written, then added to the MSI file.

*name* is the name of the CAB file in the MSI file.

*append(full, file, logical)*

Add the file with the pathname *full* to the CAB file, under the name *logical*. If there is already a file named *logical*, a new file name is created.

Return the index of the file in the CAB file, and the new name of the file inside the CAB file.

*commit(database)*

Generate a CAB file, add it as a stream to the MSI file, put it into the `Media` table, and remove the generated file from the disk.

# Directory Objects

*class msilib.Directory(database, cab, basedir, physical, logical, default[, componentflags])*

Create a new directory in the Directory table. There is a current component at each point in time for the directory, which is either explicitly created through **start\_component()**, or implicitly when files are added for the first time. Files are added into the current component, and into the cab file. To create a directory, a base directory object needs to be specified (can be `None`), the path to the physical directory, and a logical directory name. *default* specifies the DefaultDir slot in the directory table. *componentflags* specifies the default flags that new components get.

*start\_component(component = None, feature = None, flags = None, keyfile = None, uuid = None)*

Add an entry to the Component table, and make this component the current component for this directory. If no component name is given, the directory name is used. If no *feature* is given, the current feature is used. If no *flags* are given, the directory's default flags are used. If no *keyfile* is given, the KeyPath is left null in the Component table.

*add\_file(file, src = None, version = None, language = None)*

Add a file to the current component of the directory, starting a new one if there is no current component. By default, the file name in the source and the file table will be identical. If the *src* file is specified, it is interpreted relative to the current directory. Optionally, a *version* and a *language* can be specified for the entry in the File table.

*glob(pattern, exclude = None)*

Add a list of files to the current component as specified

in the glob pattern. Individual files can be excluded in the *exclude* list.

`remove_pyc()`

Remove `.pyc` files on uninstall.

## See also

[Directory Table](https://msdn.microsoft.com/en-us/library/windows/desktop/aa368295.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368295.aspx] [File Table](https://msdn.microsoft.com/en-us/library/windows/desktop/aa368596.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368596.aspx] [Component Table](https://msdn.microsoft.com/en-us/library/windows/desktop/aa368007.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368007.aspx] [FeatureComponents Table](https://msdn.microsoft.com/en-us/library/windows/desktop/aa368579.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368579.aspx]

## Features

*class* `msilib.Feature(db, id, title, desc, display, level = 1, parent = None, directory = None, attributes = 0)`

Add a new record to the `Feature` table, using the values *id*, *parent.id*, *title*, *desc*, *display*, *level*, *directory*, and *attributes*. The resulting feature object can be passed to the **`start_component()`** method of [Directory](#).

`set_current()`

Make this feature the current feature of [msilib](#). New components are automatically added to the default feature, unless a feature is explicitly specified.

## See also

[Feature Table](https://msdn.microsoft.com/en-us/library/windows/desktop/aa368585.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368585.aspx]

## GUI classes

**msilib** provides several classes that wrap the GUI tables in an MSI database. However, no standard user interface is provided.

*class* msilib.Control(*dlg*, *name*)

Base class of the dialog controls. *dlg* is the dialog object the control belongs to, and *name* is the control's name.

event(*event*, *argument*, *condition* = 1, *ordering* = None)

Make an entry into the `ControlEvent` table for this control.

mapping(*event*, *attribute*)

Make an entry into the `EventMapping` table for this control.

condition(*action*, *condition*)

Make an entry into the `ControlCondition` table for this control.

*class* msilib.RadioButtonGroup(*dlg*, *name*, *property*)

Create a radio button control named *name*. *property* is the installer property that gets set when a radio button is selected.

add(*name*, *x*, *y*, *width*, *height*, *text*, *value* = None)

Add a radio button named *name* to the group, at the coordinates *x*, *y*, *width*, *height*, and with the label *text*. If *value* is `None`, it defaults to *name*.

*class* msilib.Dialog(*db*, *name*, *x*, *y*, *w*, *h*, *attr*, *title*, *first*, *default*, *cancel*)

Return a new **Dialog** object. An entry in the `Dialog` table is made, with the specified coordinates, dialog attributes, title, name of the first, default, and cancel controls.

control(*name*, *type*, *x*, *y*, *width*, *height*, *attributes*, *property*, *text*,

*control\_next, help)*

Return a new **Control** object. An entry in the `Control` table is made with the specified parameters.

This is a generic method; for specific types, specialized methods are provided.

*text(name, x, y, width, height, attributes, text)*

Add and return a `Text` control.

*bitmap(name, x, y, width, height, text)*

Add and return a `Bitmap` control.

*line(name, x, y, width, height)*

Add and return a `Line` control.

*pushbutton(name, x, y, width, height, attributes, text, next\_control)*

Add and return a `PushButton` control.

*radiogroup(name, x, y, width, height, attributes, property, text, next\_control)*

Add and return a `RadioButtonGroup` control.

*checkbox(name, x, y, width, height, attributes, property, text, next\_control)*

Add and return a `CheckBox` control.

## Precomputed tables

**msilib** provides a few subpackages that contain only schema and table definitions. Currently, these definitions are based on MSI version 2.0.

### msilib.schema

This is the standard MSI schema for MSI 2.0, with the *tables* variable providing a list of table definitions, and *\_Validation\_records* providing the data for MSI validation.

### msilib.sequence

This module contains table contents for the standard sequence tables: *AdminExecuteSequence*, *AdminUISequence*, *AdvtExecuteSequence*, *InstallExecuteSequence*, and *InstallUISequence*.

### msilib.text

This module contains definitions for the *UIText* and *ActionText* tables, for the standard installer actions.

# **nis** — Interface to Sun's NIS (Yellow Pages)

*Deprecated since version 3.11, will be removed in version 3.13:* The **nis** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#nis) [https://peps.python.org/pep-0594/#nis] for details).

---

The **nis** module gives a thin wrapper around the NIS library, useful for central administration of several hosts.

Because NIS exists only on Unix systems, this module is only available for Unix.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

The **nis** module defines the following functions:

`nis.match(key, mapname, domain = default_domain)`

Return the match for *key* in map *mapname*, or raise an error (**nis.error**) if there is none. Both should be strings, *key* is 8-bit clean. Return value is an arbitrary array of bytes (may contain `NULL` and other joys).

Note that *mapname* is first checked if it is an alias to another name.

The *domain* argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

`nis.cat(mapname, domain = default_domain)`

Return a dictionary mapping *key* to *value* such that `match(key, mapname) == value`. Note that both keys and values of the dictionary are arbitrary arrays of bytes.

Note that *mapname* is first checked if it is an alias to another name.

The *domain* argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

`nis.maps(domain = default_domain)`

Return a list of all valid maps.

The *domain* argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

`nis.get_default_domain()`

Return the system default NIS domain.

The **nis** module defines the following exception:

*exception* `nis.error`

An error raised when a NIS function returns an error code.

# nntplib — NNTP protocol client

**Source code:** [Lib/nntplib.py](https://github.com/python/cpython/tree/3.12/Lib/nntplib.py) [https://github.com/python/cpython/tree/3.12/Lib/nntplib.py]

*Deprecated since version 3.11:* The **nntplib** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/) [https://peps.python.org/pep-0594/] for details).

---

This module defines the class **NNTP** which implements the client side of the Network News Transfer Protocol. It can be used to implement a news reader or poster, or automated news processors. It is compatible with [RFC 3977](https://datatracker.ietf.org/doc/html/rfc3977.html) [https://datatracker.ietf.org/doc/html/rfc3977.html] as well as the older [RFC 977](https://datatracker.ietf.org/doc/html/rfc977.html) [https://datatracker.ietf.org/doc/html/rfc977.html] and [RFC 2980](https://datatracker.ietf.org/doc/html/rfc2980.html) [https://datatracker.ietf.org/doc/html/rfc2980.html].

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

Here are two small examples of how it can be used. To list some statistics about a newsgroup and print the subjects of the last 10 articles:

```
>>> s = nntplib.NNTP('news.gmane.io')
>>> resp, count, first, last, name = s.group('gmane.comp.python')
>>> print('Group', name, 'has', count, 'articles, range', first, last)
Group gmane.comp.python.committers has 1096 articles, range 1-1096
>>> resp, overviews = s.over((last - 9, last))
>>> for id, over in overviews:
...     print(id, nntplib.decode_header(over['subject']))
... 
```

```
1087 Re: Commit privileges for Łukasz Langa
1088 Re: 3.2 alpha 2 freeze
1089 Re: 3.2 alpha 2 freeze
1090 Re: Commit privileges for Łukasz Langa
1091 Re: Commit privileges for Łukasz Langa
1092 Updated ssh key
1093 Re: Updated ssh key
1094 Re: Updated ssh key
1095 Hello fellow committers!
1096 Re: Hello fellow committers!
>>> s.quit()
'205 Bye!'
```

To post an article from a binary file (this assumes that the article has valid headers, and that you have right to post on the particular newsgroup):

```
>>> s = nntplib.NNTP('news.gmane.io')
>>> f = open('article.txt', 'rb')
>>> s.post(f)
'240 Article posted successfully.'
>>> s.quit()
'205 Bye!'
```

The module itself defines the following classes:

```
class nntplib.NNTP(host, port=119, user=None, password=None,
readermode=None, usenetrc=False[, timeout])
```

Return a new **NNTP** object, representing a connection to the NNTP server running on host *host*, listening at port *port*. An optional *timeout* can be specified for the socket connection. If the optional *user* and *password* are provided, or if suitable credentials are present in `/.netrc` and the optional flag *usenetrc* is true, the `AUTHINFO USER` and `AUTHINFO PASS` commands are used to identify and authenticate the user to the server. If the optional flag *readermode* is true, then a mode `reader` command is sent before authentication is performed. Reader mode is sometimes necessary if you are connecting to an NNTP server on the local machine and

intend to call reader-specific commands, such as `group`. If you get unexpected [NNTPPermanentErrors](#), you might need to set `readermode`. The [NNTP](#) class supports the `with` statement to unconditionally consume [OSError](#) exceptions and to close the NNTP connection when done, e.g.:

```
>>> from nntplib import NNTP
>>> with NNTP('news.gmane.io') as n:
...     n.group('gmane.comp.python.committers')
...
('211 1755 1 1755 gmane.comp.python.committers', 17
>>>
```

Raises an [auditing event](#) `nntplib.connect` with arguments `self`, `host`, `port`.

All commands will raise an [auditing event](#) `nntplib.putline` with arguments `self` and `line`, where `line` is the bytes about to be sent to the remote host.

*Changed in version 3.2:* `usenetr` is now `False` by default.

*Changed in version 3.3:* Support for the `with` statement was added.

*Changed in version 3.9:* If the `timeout` parameter is set to be zero, it will raise a [ValueError](#) to prevent the creation of a non-blocking socket.

```
class nntplib.NNTP_SSL(host, port=563, user=None,
password=None, ssl_context=None, readermode=None,
usenetr=False[, timeout])
```

Return a new [NNTP\\_SSL](#) object, representing an encrypted connection to the NNTP server running on host `host`, listening at port `port`. [NNTP\\_SSL](#) objects have the same methods as [NNTP](#) objects. If `port` is omitted, port 563 (NNTPS) is used. `ssl_context` is also optional, and is a [SSLContext](#) object. Please read [Security considerations](#) for best practices. All other parameters behave the same as for [NNTP](#).

Note that SSL-on-563 is discouraged per [RFC 4642](https://datatracker.ietf.org/doc/html/rfc4642.html) [https://datatracker.ietf.org/doc/html/rfc4642.html], in favor of STARTTLS as described below. However, some servers only support the former.

Raises an [auditing event](#) `nntplib.connect` with arguments `self`, `host`, `port`.

All commands will raise an [auditing event](#) `nntplib.putline` with arguments `self` and `line`, where `line` is the bytes about to be sent to the remote host.

*New in version 3.2.*

*Changed in version 3.4:* The class now supports hostname check with `ssl.SSLContext.check_hostname` and *Server Name Indication* (see `ssl.HAS_SNI`).

*Changed in version 3.9:* If the `timeout` parameter is set to be zero, it will raise a [ValueError](#) to prevent the creation of a non-blocking socket.

*exception* `nntplib.NNTPError`

Derived from the standard exception [Exception](#), this is the base class for all exceptions raised by the `nntplib` module. Instances of this class have the following attribute:

`response`

The response of the server if available, as a [str](#) object.

*exception* `nntplib.NNTPReplyError`

Exception raised when an unexpected reply is received from the server.

*exception* `nntplib.NNTPTemporaryError`

Exception raised when a response code in the range 400–499 is received.

*exception* `nntplib.NNTPPermanentError`

Exception raised when a response code in the range 500–599 is received.

*exception* `nntplib.NNTPProtocolError`

Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5.

*exception* `nntplib.NNTPDataError`

Exception raised when there is some error in the response data.

## NNTP Objects

When connected, `NNTP` and `NNTP_SSL` objects support the following methods and attributes.

### Attributes

`NNTP.nntp_version`

An integer representing the version of the NNTP protocol supported by the server. In practice, this should be 2 for servers advertising [RFC 3977](https://datatracker.ietf.org/doc/html/rfc3977) [https://datatracker.ietf.org/doc/html/rfc3977.html] compliance and 1 for others.

*New in version 3.2.*

`NNTP.nntp_implementation`

A string describing the software name and version of the NNTP server, or `None` if not advertised by the server.

*New in version 3.2.*

### Methods

The *response* that is returned as the first item in the return tuple of almost all methods is the server's response: a string beginning with a three-digit code. If the server's response indicates an error, the method raises one of the above exceptions.

Many of the following methods take an optional keyword-only argument *file*. When the *file* argument is supplied, it must be either a [file object](#) opened for binary writing, or the name of an on-disk file to be written to. The method will then write any data returned by the server (except for the response line and the terminating dot) to the file; any list of lines, tuples or objects that the method normally returns will be empty.

*Changed in version 3.2:* Many of the following methods have been reworked and fixed, which makes them incompatible with their 3.1 counterparts.

### NNTP.quit()

Send a `QUIT` command and close the connection. Once this method has been called, no other methods of the `NNTP` object should be called.

### NNTP.getwelcome()

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

### NNTP.getcapabilities()

Return the [RFC 3977](#) [<https://datatracker.ietf.org/doc/html/rfc3977.html>] capabilities advertised by the server, as a [dict](#) instance mapping capability names to (possibly empty) lists of values. On legacy servers which don't understand the `CAPABILITIES` command, an empty dictionary is returned instead.

```
>>> s = NNTP('news.gmane.io')
>>> 'POST' in s.getcapabilities()
True
```

*New in version 3.2.*

`NNTP.login(user=None, password=None, usenetrc=True)`

Send `AUTHINFO` commands with the user name and password. If *user* and *password* are `None` and *usenetcrc* is true, credentials from `~/.netrc` will be used if possible.

Unless intentionally delayed, login is normally performed during the `NNTP` object initialization and separately calling this function is unnecessary. To force authentication to be delayed, you must not set *user* or *password* when creating the object, and must set *usenetcrc* to `False`.

*New in version 3.2.*

`NNTP.starttls(context=None)`

Send a `STARTTLS` command. This will enable encryption on the `NNTP` connection. The *context* argument is optional and should be a `ssl.SSLContext` object. Please read [Security considerations](#) for best practices.

Note that this may not be done after authentication information has been transmitted, and authentication occurs by default if possible during a `NNTP` object initialization. See `NNTP.login()` for information on suppressing this behavior.

*New in version 3.2.*

*Changed in version 3.4:* The method now supports hostname check with `ssl.SSLContext.check_hostname` and *Server Name Indication* (see `ssl.HAS_SNI`).

`NNTP.newgroups(date, *, file=None)`

Send a `NEWGROUPS` command. The *date* argument should be a `datetime.date` or `datetime.datetime` object. Return a pair (*response*, *groups*) where *groups* is a list representing the groups that are new since the given *date*. If *file* is supplied, though, then *groups* will be empty.

```
>>> from datetime import date, timedelta
>>> resp, groups = s.newgroups(date.today() - timed
>>> len(groups)
```

```
>>> groups[0]  
GroupInfo(group='gmane.network.tor.devel', last='4'
```

`NNTP.newnews(group, date, *, file=None)`

Send a `NEWNEWS` command. Here, *group* is a group name or `'*'`, and *date* has the same meaning as for `newgroups()`. Return a pair (*response*, *articles*) where *articles* is a list of message ids.

This command is frequently disabled by NNTP server administrators.

`NNTP.list(group_pattern=None, *, file=None)`

Send a `LIST` or `LIST ACTIVE` command. Return a pair (*response*, *list*) where *list* is a list of tuples representing all the groups available from this NNTP server, optionally matching the pattern string *group\_pattern*. Each tuple has the form (*group*, *last*, *first*, *flag*), where *group* is a group name, *last* and *first* are the last and first article numbers, and *flag* usually takes one of these values:

- *y*: Local postings and articles from peers are allowed.
- *m*: The group is moderated and all postings must be approved.
- *n*: No local postings are allowed, only articles from peers.
- *j*: Articles from peers are filed in the junk group instead.
- *x*: No local postings, and articles from peers are ignored.
- *=foo.bar*: Articles are filed in the *foo.bar* group instead.

If *flag* has another value, then the status of the newsgroup should be considered unknown.

This command can return very large results, especially if *group\_pattern* is not specified. It is best to cache the results offline unless you really need to refresh them.

*Changed in version 3.2: `group_pattern` was added.*

### NNTP.descriptions(*grouppattern*)

Send a `LIST NEWSGROUPS` command, where *grouppattern* is a wildmat string as specified in [RFC 3977](https://datatracker.ietf.org/doc/html/rfc3977) [https://datatracker.ietf.org/doc/html/rfc3977.html] (it's essentially the same as DOS or UNIX shell wildcard strings). Return a pair (*response*, *descriptions*), where *descriptions* is a dictionary mapping group names to textual descriptions.

```
>>> resp, descs = s.descriptions('gmane.comp.python')
>>> len(descs)
295
>>> descs.popitem()
('gmane.comp.python.bio.general', 'BioPython discuss')
```

### NNTP.description(*group*)

Get a description for a single group *group*. If more than one group matches (if 'group' is a real wildmat string), return the first match. If no group matches, return an empty string.

This elides the response code from the server. If the response code is needed, use [descriptions\(\)](#).

### NNTP.group(*name*)

Send a `GROUP` command, where *name* is the group name. The group is selected as the current group, if it exists. Return a tuple (*response*, *count*, *first*, *last*, *name*) where *count* is the (estimated) number of articles in the group, *first* is the first article number in the group, *last* is the last article number in the group, and *name* is the group name.

### NNTP.over(*message\_spec*, \*, *file* = None)

Send an `OVER` command, or an `XOVER` command on legacy servers. *message\_spec* can be either a string representing a message id, or a (*first*, *last*) tuple of numbers indicating a range of articles in the current group, or a (*first*, None) tuple indicating a range of articles starting

from *first* to the last article in the current group, or **None** to select the current article in the current group.

Return a pair (response, overviews). *overviews* is a list of (article\_number, overview) tuples, one for each article selected by *message\_spec*. Each *overview* is a dictionary with the same number of items, but this number depends on the server. These items are either message headers (the key is then the lower-cased header name) or metadata items (the key is then the metadata name prepended with ": "). The following items are guaranteed to be present by the NNTP specification:

- the subject, from, date, message-id and references headers
- the :bytes metadata: the number of bytes in the entire raw article (including headers and body)
- the :lines metadata: the number of lines in the article body

The value of each item is either a string, or **None** if not present.

It is advisable to use the **decode\_header()** function on header values when they may contain non-ASCII characters:

```
>>> _, _, first, last, _ = s.group('gmane.comp.pyth
>>> resp, overviews = s.over((last, last))
>>> art_num, over = overviews[0]
>>> art_num
117216
>>> list(over.keys())
['xref', 'from', ':lines', ':bytes', 'references',
>>> over['from']
'=?UTF-8?B?Ik1hcnRpbIB2LiBMw7Z3aXMi?= <martin@v.loe
>>> nntplib.decode_header(over['from'])
'"Martin v. Löwis" <martin@v.loewis.de>'
```

*New in version 3.2.*

`NNTP.help(*, file=None)`

Send a `HELP` command. Return a pair `(response, list)` where `list` is a list of help strings.

`NNTP.stat(message_spec=None)`

Send a `STAT` command, where `message_spec` is either a message id (enclosed in `'<'` and `'>'`) or an article number in the current group. If `message_spec` is omitted or `None`, the current article in the current group is considered. Return a triple `(response, number, id)` where `number` is the article number and `id` is the message id.

```
>>> _, _, first, last, _ = s.group('gmane.comp.pyth
>>> resp, number, message_id = s.stat(first)
>>> number, message_id
(9099, '<20030112190404.GE29873@epoch.metaslash.com
```

`NNTP.next()`

Send a `NEXT` command. Return as for `stat()`.

`NNTP.last()`

Send a `LAST` command. Return as for `stat()`.

`NNTP.article(message_spec=None, *, file=None)`

Send an `ARTICLE` command, where `message_spec` has the same meaning as for `stat()`. Return a tuple `(response, info)` where `info` is a `namedtuple` with three attributes `number`, `message_id` and `lines` (in that order). `number` is the article number in the group (or 0 if the information is not available), `message_id` the message id as a string, and `lines` a list of lines (without terminating newlines) comprising the raw message including headers and body.

```
>>> resp, info = s.article('<20030112190404.GE29873
>>> info.number
0
>>> info.message_id
```

```
'<20030112190404.GE29873@epoch.metaslash.com>'
>>> len(info.lines)
65
>>> info.lines[0]
b'Path: main.gmane.org!not-for-mail'
>>> info.lines[1]
b'From: Neal Norwitz <neal@metaslash.com>'
>>> info.lines[-3:]
[b'There is a patch for 2.3 as well as 2.2.', b'', b'']
```

**NNTP.head(*message\_spec=None*, \*, *file=None*)**

Same as **article()**, but sends a HEAD command. The *lines* returned (or written to *file*) will only contain the message headers, not the body.

**NNTP.body(*message\_spec=None*, \*, *file=None*)**

Same as **article()**, but sends a BODY command. The *lines* returned (or written to *file*) will only contain the message body, not the headers.

**NNTP.post(*data*)**

Post an article using the POST command. The *data* argument is either a **file object** opened for binary reading, or any iterable of bytes objects (representing raw lines of the article to be posted). It should represent a well-formed news article, including the required headers. The **post()** method automatically escapes lines beginning with . and appends the termination line.

If the method succeeds, the server's response is returned. If the server refuses posting, a **NNTPReplyError** is raised.

**NNTP.ihave(*message\_id*, *data*)**

Send an IHAVE command. *message\_id* is the id of the message to send to the server (enclosed in '<' and '>'). The *data* parameter and the return value are the same as for **post()**.

NNTP.date()

Return a pair (response, date). *date* is a [datetime](#) object containing the current date and time of the server.

NNTP.slave()

Send a SLAVE command. Return the server's *response*.

NNTP.set\_debuglevel(*level*)

Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request or response. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the connection (including message text).

The following are optional NNTP extensions defined in [RFC 2980](#) [<https://datatracker.ietf.org/doc/html/rfc2980.html>]. Some of them have been superseded by newer commands in [RFC 3977](#) [<https://datatracker.ietf.org/doc/html/rfc3977.html>].

NNTP.xhdr(*hdr*, *str*, \*, *file*=None)

Send an XHDR command. The *hdr* argument is a header keyword, e.g. 'subject'. The *str* argument should have the form 'first-last' where *first* and *last* are the first and last article numbers to search. Return a pair (response, list), where *list* is a list of pairs (id, text), where *id* is an article number (as a string) and *text* is the text of the requested header for that article. If the *file* parameter is supplied, then the output of the XHDR command is stored in a file. If *file* is a string, then the method will open a file with that name, write to it then close it. If *file* is a [file object](#), then it will start calling **write()** on it to store the lines of the command output. If *file* is supplied, then the returned *list* is an empty list.

NNTP.xover(*start*, *end*, \*, *file*=None)

Send an `XOVER` command. *start* and *end* are article numbers delimiting the range of articles to select. The return value is the same of for `over()`. It is recommended to use `over()` instead, since it will automatically use the newer `OVER` command if available.

## Utility functions

The module also defines the following utility function:

`nntplib.decode_header(header_str)`

Decode a header value, un-escaping any escaped non-ASCII characters. *header\_str* must be a `str` object. The unescaped value is returned. Using this function is recommended to display some headers in a human readable form:

```
>>> decode_header("Some subject")
'Some subject'
>>> decode_header("=?ISO-8859-15?Q?D=E9buter_en_Pyt
'Débuter en Python'
>>> decode_header("Re: =?UTF-8?B?cHJvYmzDqG1lIGRlIG
'Re: problème de matrice')
```

# optparse — Parser for command line options

**Source code:** [Lib/optparse.py](https://github.com/python/cpython/tree/3.12/Lib/optparse.py) [https://github.com/python/cpython/tree/3.12/Lib/optparse.py]

*Deprecated since version 3.2:* The **optparse** module is deprecated and will not be developed further; development will continue with the **argparse** module.

---

**optparse** is a more convenient, flexible, and powerful library for parsing command-line options than the old **getopt** module. **optparse** uses a more declarative style of command-line parsing: you create an instance of **OptionParser**, populate it with options, and parse the command line. **optparse** allows users to specify options in the conventional GNU/POSIX syntax, and additionally generates usage and help messages for you.

Here's an example of using **optparse** in a simple script:

```
from optparse import OptionParser
...
parser = OptionParser()
parser.add_option("-f", "--file", dest="filename",
                  help="write report to FILE", metavar="FILE",)
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose",
                  help="don't print status messages to s

(options, args) = parser.parse_args()
```

With these few lines of code, users of your script can now do the “usual thing” on the command-line, for example:

```
<yourscript> --file=outfile -q
```

As it parses the command line, `optparse` sets attributes of the options object returned by `parse_args()` based on user-supplied command-line values. When `parse_args()` returns from parsing this command line, `options.filename` will be "outfile" and `options.verbose` will be `False`. `optparse` supports both long and short options, allows short options to be merged together, and allows options to be associated with their arguments in a variety of ways. Thus, the following command lines are all equivalent to the above example:

```
<yourscript> -f outfile --quiet
<yourscript> --quiet --file outfile
<yourscript> -q -foutfile
<yourscript> -qfoutfile
```

Additionally, users can run one of the following

```
<yourscript> -h
<yourscript> --help
```

and `optparse` will print out a brief summary of your script's options:

Usage: `<yourscript> [options]`

Options:

<code>-h, --help</code>	show this help message and exit
<code>-f FILE, --file=FILE</code>	write report to FILE
<code>-q, --quiet</code>	don't print status messages to s

where the value of *yourscript* is determined at runtime (normally from `sys.argv[0]`).

## Background

`optparse` was explicitly designed to encourage the creation of programs with straightforward, conventional command-line interfaces. To that end, it supports only the most common command-line syntax and semantics conventionally used under Unix. If you are unfamiliar with these conventions, read this section

to acquaint yourself with them.

## Terminology

### argument

a string entered on the command-line, and passed by the shell to `exec1()` or `execv()`. In Python, arguments are elements of `sys.argv[1:]` (`sys.argv[0]` is the name of the program being executed). Unix shells also use the term “word”.

It is occasionally desirable to substitute an argument list other than `sys.argv[1:]`, so you should read “argument” as “an element of `sys.argv[1:]`, or of some other list provided as a substitute for `sys.argv[1:]`”.

### option

an argument used to supply extra information to guide or customize the execution of a program. There are many different syntaxes for options; the traditional Unix syntax is a hyphen (“-”) followed by a single letter, e.g. `-x` or `-F`. Also, traditional Unix syntax allows multiple options to be merged into a single argument, e.g. `-x -F` is equivalent to `-xF`. The GNU project introduced `--` followed by a series of hyphen-separated words, e.g. `--file` or `--dry-run`. These are the only two option syntaxes provided by [optparse](#).

Some other option syntaxes that the world has seen include:

- a hyphen followed by a few letters, e.g. `-pf` (this is *not* the same as multiple options merged into a single argument)
- a hyphen followed by a whole word, e.g. `-file` (this is technically equivalent to the previous syntax, but they aren’t usually seen in the same program)
- a plus sign followed by a single letter, or a few letters, or a word, e.g. `+f`, `+rgb`
- a slash followed by a letter, or a few letters, or a word, e.g. `/f`, `/file`

These option syntaxes are not supported by `optparse`, and they never will be. This is deliberate: the first three are non-standard on any environment, and the last only makes sense if you're exclusively targeting Windows or certain legacy platforms (e.g. VMS, MS-DOS).

#### option argument

an argument that follows an option, is closely associated with that option, and is consumed from the argument list when that option is. With `optparse`, option arguments may either be in a separate argument from their option:

```
-f foo
--file foo
```

or included in the same argument:

```
-ffoo
--file=foo
```

Typically, a given option either takes an argument or it doesn't. Lots of people want an "optional option arguments" feature, meaning that some options will take an argument if they see it, and won't if they don't. This is somewhat controversial, because it makes parsing ambiguous: if `-a` takes an optional argument and `-b` is another option entirely, how do we interpret `-ab`? Because of this ambiguity, `optparse` does not support this feature.

#### positional argument

something leftover in the argument list after options have been parsed, i.e. after options and their arguments have been parsed and removed from the argument list.

#### required option

an option that must be supplied on the command-line; note that the phrase "required option" is self-contradictory in English. `optparse` doesn't prevent you from implementing required options, but doesn't give you much help at it either.

For example, consider this hypothetical command-line:

```
prog -v --report report.txt foo bar
```

`-v` and `--report` are both options. Assuming that `--report` takes one argument, `report.txt` is an option argument. `foo` and `bar` are positional arguments.

## What are options for?

Options are used to provide extra information to tune or customize the execution of a program. In case it wasn't clear, options are usually *optional*. A program should be able to run just fine with no options whatsoever. (Pick a random program from the Unix or GNU toolsets. Can it run without any options at all and still make sense? The main exceptions are `find`, `tar`, and `dd`—all of which are mutant oddballs that have been rightly criticized for their non-standard syntax and confusing interfaces.)

Lots of people want their programs to have “required options”. Think about it. If it's required, then it's *not optional*! If there is a piece of information that your program absolutely requires in order to run successfully, that's what positional arguments are for.

As an example of good command-line interface design, consider the humble `cp` utility, for copying files. It doesn't make much sense to try to copy files without supplying a destination and at least one source. Hence, `cp` fails if you run it with no arguments. However, it has a flexible, useful syntax that does not require any options at all:

```
cp SOURCE DEST
cp SOURCE ... DEST-DIR
```

You can get pretty far with just that. Most `cp` implementations provide a bunch of options to tweak exactly how the files are copied: you can preserve mode and modification time, avoid following symlinks, ask before clobbering existing files, etc. But none of this distracts from the core mission of `cp`, which is to copy either one file to another, or several files to another directory.

## What are positional arguments for?

Positional arguments are for those pieces of information that your program absolutely, positively requires to run.

A good user interface should have as few absolute requirements as possible. If your program requires 17 distinct pieces of information in order to run successfully, it doesn't much matter *how* you get that information from the user—most people will give up and walk away before they successfully run the program. This applies whether the user interface is a command-line, a configuration file, or a GUI: if you make that many demands on your users, most of them will simply give up.

In short, try to minimize the amount of information that users are absolutely required to supply—use sensible defaults whenever possible. Of course, you also want to make your programs reasonably flexible. That's what options are for. Again, it doesn't matter if they are entries in a config file, widgets in the “Preferences” dialog of a GUI, or command-line options—the more options you implement, the more flexible your program is, and the more complicated its implementation becomes. Too much flexibility has drawbacks as well, of course; too many options can overwhelm users and make your code much harder to maintain.

## Tutorial

While `optparse` is quite flexible and powerful, it's also straightforward to use in most cases. This section covers the code patterns that are common to any `optparse`-based program.

First, you need to import the `OptionParser` class; then, early in the main program, create an `OptionParser` instance:

```
from optparse import OptionParser
...
parser = OptionParser()
```

Then you can start defining options. The basic syntax is:

```
parser.add_option(opt_str, ...,
                  attr=value, ...)
```

Each option has one or more option strings, such as `-f` or `--file`, and several option attributes that tell `optparse` what to expect and what to do when it encounters that option on the command line.

Typically, each option will have one short option string and one long option string, e.g.:

```
parser.add_option("-f", "--file", ...)
```

You're free to define as many short option strings and as many long option strings as you like (including zero), as long as there is at least one option string overall.

The option strings passed to `OptionParser.add_option()` are effectively labels for the option defined by that call. For brevity, we will frequently refer to *encountering an option* on the command line; in reality, `optparse` encounters *option strings* and looks up options from them.

Once all of your options are defined, instruct `optparse` to parse your program's command line:

```
(options, args) = parser.parse_args()
```

(If you like, you can pass a custom argument list to `parse_args()`, but that's rarely necessary: by default it uses `sys.argv[1:]`.)

`parse_args()` returns two values:

- `options`, an object containing values for all of your options —e.g. if `--file` takes a single string argument, then `options.file` will be the filename supplied by the user, or `None` if the user did not supply that option
- `args`, the list of positional arguments leftover after parsing options

This tutorial section only covers the four most important option

attributes: **action**, **type**, **dest** (destination), and **help**. Of these, **action** is the most fundamental.

## Understanding option actions

Actions tell **optparse** what to do when it encounters an option on the command line. There is a fixed set of actions hard-coded into **optparse**; adding new actions is an advanced topic covered in section **Extending optparse**. Most actions tell **optparse** to store a value in some variable—for example, take a string from the command line and store it in an attribute of `options`.

If you don't specify an option action, **optparse** defaults to `store`.

### The store action

The most common option action is `store`, which tells **optparse** to take the next argument (or the remainder of the current argument), ensure that it is of the correct type, and store it to your chosen destination.

For example:

```
parser.add_option("-f", "--file",  
                  action="store", type="string", dest="f")
```

Now let's make up a fake command line and ask **optparse** to parse it:

```
args = ["-f", "foo.txt"]  
(options, args) = parser.parse_args(args)
```

When **optparse** sees the option string `-f`, it consumes the next argument, `foo.txt`, and stores it in `options.filename`. So, after this call to **parse\_args()**, `options.filename` is `"foo.txt"`.

Some other option types supported by **optparse** are `int` and `float`. Here's an option that expects an integer argument:

```
parser.add_option("-n", type="int", dest="num")
```

Note that this option has no long option string, which is perfectly acceptable. Also, there's no explicit action, since the default is `store`.

Let's parse another fake command-line. This time, we'll jam the option argument right up against the option: since `-n42` (one argument) is equivalent to `-n 42` (two arguments), the code

```
(options, args) = parser.parse_args(["-n42"])
print(options.num)
```

will print `42`.

If you don't specify a type, `optparse` assumes `string`. Combined with the fact that the default action is `store`, that means our first example can be a lot shorter:

```
parser.add_option("-f", "--file", dest="filename")
```

If you don't supply a destination, `optparse` figures out a sensible default from the option strings: if the first long option string is `--foo-bar`, then the default destination is `foo_bar`. If there are no long option strings, `optparse` looks at the first short option string: the default destination for `-f` is `f`.

`optparse` also includes the built-in `complex` type. Adding types is covered in section [Extending optparse](#).

## Handling boolean (flag) options

Flag options—set a variable to true or false when a particular option is seen—are quite common. `optparse` supports them with two separate actions, `store_true` and `store_false`. For example, you might have a `verbose` flag that is turned on with `-v` and off with `-q`:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose")
```

Here we have two different options with the same destination, which is perfectly OK. (It just means you have to be a bit careful when setting default values—see below.)

When `optparse` encounters `-v` on the command line, it sets `options.verbose` to `True`; when it encounters `-q`, `options.verbose` is set to `False`.

## Other actions

Some other actions supported by `optparse` are:

```
"store_const"  
    store a constant value, pre-set via Option.const  
  
"append"  
    append this option's argument to a list  
  
"count"  
    increment a counter by one  
  
"callback"  
    call a specified function
```

These are covered in section [Reference Guide](#), and section [Option Callbacks](#).

## Default values

All of the above examples involve setting some variable (the “destination”) when certain command-line options are seen. What happens if those options are never seen? Since we didn’t supply any defaults, they are all set to `None`. This is usually fine, but sometimes you want more control. `optparse` lets you supply a default value for each destination, which is assigned before the command line is parsed.

First, consider the verbose/quiet example. If we want `optparse` to set `verbose` to `True` unless `-q` is seen, then we can do this:

```
parser.add_option("-v", action="store_true", dest="verbose")
```

```
parser.add_option("-q", action="store_false", dest="verbose")
```

Since default values apply to the *destination* rather than to any particular option, and these two options happen to have the same destination, this is exactly equivalent:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose")
```

Consider this:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose")
```

Again, the default value for `verbose` will be `True`: the last default value supplied for any particular destination is the one that counts.

A clearer way to specify default values is the `set_defaults()` method of `OptionParser`, which you can call at any time before calling `parse_args()`:

```
parser.set_defaults(verbose=True)
parser.add_option(...)
(options, args) = parser.parse_args()
```

As before, the last value specified for a given option destination is the one that counts. For clarity, try to use one method or the other of setting default values, not both.

## Generating help

`optparse`'s ability to generate help and usage text automatically is useful for creating user-friendly command-line interfaces. All you have to do is supply a `help` value for each option, and optionally a short usage message for your whole program. Here's an `OptionParser` populated with user-friendly (documented) options:

```
usage = "usage: %prog [options] arg1 arg2"
parser = OptionParser(usage=usage)
parser.add_option("-v", "--verbose",
```

```

        action="store_true", dest="verbose",
        help="make lots of noise [default]")
parser.add_option("-q", "--quiet",
        action="store_false", dest="verbose",
        help="be vewwy quiet (I'm hunting wabb")
parser.add_option("-f", "--filename",
        metavar="FILE", help="write output to")
parser.add_option("-m", "--mode",
        default="intermediate",
        help="interaction mode: novice, intern
        "or expert [default: %default]")

```

If **optparse** encounters either `-h` or `--help` on the command-line, or if you just call **`parser.print_help()`**, it prints the following to standard output:

Usage: <yourscript> [options] arg1 arg2

Options:

```

-h, --help            show this help message and exit
-v, --verbose         make lots of noise [default]
-q, --quiet          be vewwy quiet (I'm hunting wabb
-f FILE, --filename=FILE
                     write output to FILE
-m MODE, --mode=MODE  interaction mode: novice, intern
                     expert [default: intermediate]

```

(If the help output is triggered by a help option, **optparse** exits after printing the help text.)

There's a lot going on here to help **optparse** generate the best possible help message:

- the script defines its own usage message:

```
usage = "usage: %prog [options] arg1 arg2"
```

**optparse** expands `%prog` in the usage string to the name of the current program, i.e.

`os.path.basename(sys.argv[0])`. The expanded string

is then printed before the detailed option help.

If you don't supply a usage string, `optparse` uses a bland but sensible default: `"Usage: %prog [options]"`, which is fine if your script doesn't take any positional arguments.

- every option defines a help string, and doesn't worry about line-wrapping—`optparse` takes care of wrapping lines and making the help output look good.
- options that take a value indicate this fact in their automatically generated help message, e.g. for the “mode” option:

```
-m MODE, --mode=MODE
```

Here, “MODE” is called the meta-variable: it stands for the argument that the user is expected to supply to `-m/--mode`. By default, `optparse` converts the destination variable name to uppercase and uses that for the meta-variable. Sometimes, that's not what you want—for example, the `--filename` option explicitly sets `metavar="FILE"`, resulting in this automatically generated option description:

```
-f FILE, --filename=FILE
```

This is important for more than just saving space, though: the manually written help text uses the meta-variable `FILE` to clue the user in that there's a connection between the semi-formal syntax `-f FILE` and the informal semantic description “write output to `FILE`”. This is a simple but effective way to make your help text a lot clearer and more useful for end users.

- options that have a default value can include `%default` in the help string—`optparse` will replace it with `str()` of the option's default value. If an option has no default value (or the default value is `None`), `%default` expands to `none`.

## Grouping Options

When dealing with many options, it is convenient to group these options for better help output. An `OptionParser` can contain several option groups, each of which can contain several options.

An option group is obtained using the class `OptionGroup`:

```
class optparse.OptionGroup(parser, title, description=None)
    where
```

- `parser` is the `OptionParser` instance the group will be inserted in to
- `title` is the group title
- `description`, optional, is a long description of the group

`OptionGroup` inherits from `OptionContainer` (like `OptionParser`) and so the `add_option()` method can be used to add an option to the group.

Once all the options are declared, using the `OptionParser` method `add_option_group()` the group is added to the previously defined parser.

Continuing with the parser defined in the previous section, adding an `OptionGroup` to a parser is easy:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk",
                    "It is believed that some of them bite")
group.add_option("-g", action="store_true", help="Group options")
parser.add_option_group(group)
```

This would result in the following help output:

```
Usage: <yourscript> [options] arg1 arg2
```

```
Options:
```

```
-h, --help            show this help message and exit
-v, --verbose          make lots of noise [default]
-q, --quiet            be vewwy quiet (I'm hunting wabb
-f FILE, --filename=FILE
```

```
                                write output to FILE
-m MODE, --mode=MODE          interaction mode: novice, intern
                                expert [default: intermediate]
```

#### Dangerous Options:

Caution: use these options at your own risk. It is of them bite.

```
-g                                Group option.
```

**A bit more complete example might involve using more than one group: still extending the previous example:**

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your
                    "It is believed that some of them bi
group.add_option("-g", action="store_true", help="Group
parser.add_option_group(group)
```

```
group = OptionGroup(parser, "Debug Options")
group.add_option("-d", "--debug", action="store_true",
                help="Print debug information")
group.add_option("-s", "--sql", action="store_true",
                help="Print all SQL statements executed
group.add_option("-e", action="store_true", help="Print
parser.add_option_group(group)
```

**that results in the following output:**

Usage: <yourscript> [options] arg1 arg2

#### Options:

```
-h, --help                show this help message and exit
-v, --verbose             make lots of noise [default]
-q, --quiet              be vewwy quiet (I'm hunting wabb
-f FILE, --filename=FILE
                        write output to FILE
-m MODE, --mode=MODE     interaction mode: novice, intern
                        [default: intermediate]
```

### Dangerous Options:

Caution: use these options at your own risk. It is of them bite.

`-g`                      Group option.

### Debug Options:

<code>-d, --debug</code>	Print debug information
<code>-s, --sql</code>	Print all SQL statements executed
<code>-e</code>	Print every action done

Another interesting method, in particular when working programmatically with option groups is:

### `OptionParser.get_option_group(opt_str)`

Return the `OptionGroup` to which the short or long option string `opt_str` (e.g. `'-o'` or `'--option'`) belongs. If there's no such `OptionGroup`, return `None`.

## Printing a version string

Similar to the brief usage string, `optparse` can also print a version string for your program. You have to supply the string as the version argument to `OptionParser`:

```
parser = OptionParser(usage="%prog [-f] [-q]", version="")
```

`%prog` is expanded just like it is in `usage`. Apart from that, `version` can contain anything you like. When you supply it, `optparse` automatically adds a `--version` option to your parser. If it encounters this option on the command line, it expands your version string (by replacing `%prog`), prints it to `stdout`, and exits.

For example, if your script is called `/usr/bin/foo`:

```
$ /usr/bin/foo --version
foo 1.0
```

The following two methods can be used to print and get the

version string:

`OptionParser.print_version(file=None)`

Print the version message for the current program (`self.version`) to *file* (default `stdout`). As with `print_usage()`, any occurrence of `%prog` in `self.version` is replaced with the name of the current program. Does nothing if `self.version` is empty or undefined.

`OptionParser.get_version()`

Same as `print_version()` but returns the version string instead of printing it.

## How `optparse` handles errors

There are two broad classes of errors that `optparse` has to worry about: programmer errors and user errors. Programmer errors are usually erroneous calls to `OptionParser.add_option()`, e.g. invalid option strings, unknown option attributes, missing option attributes, etc. These are dealt with in the usual way: raise an exception (either `optparse.OptionError` or `TypeError`) and let the program crash.

Handling user errors is much more important, since they are guaranteed to happen no matter how stable your code is. `optparse` can automatically detect some user errors, such as bad option arguments (passing `-n 4x` where `-n` takes an integer argument), missing arguments (`-n` at the end of the command line, where `-n` takes an argument of any type). Also, you can call `OptionParser.error()` to signal an application-defined error condition:

```
(options, args) = parser.parse_args()
...
if options.a and options.b:
    parser.error("options -a and -b are mutually exclusi
```

In either case, `optparse` handles the error the same way: it prints

the program's usage message and an error message to standard error and exits with error status 2.

Consider the first example above, where the user passes `4x` to an option that takes an integer:

```
$ /usr/bin/foo -n 4x
Usage: foo [options]
```

```
foo: error: option -n: invalid integer value: '4x'
```

Or, where the user fails to pass a value at all:

```
$ /usr/bin/foo -n
Usage: foo [options]
```

```
foo: error: -n option requires an argument
```

**optparse**-generated error messages take care always to mention the option involved in the error; be sure to do the same when calling **OptionParser.error()** from your application code.

If **optparse**'s default error-handling behaviour does not suit your needs, you'll need to subclass **OptionParser** and override its **exit()** and/or **error()** methods.

## Putting it all together

Here's what **optparse**-based scripts usually look like:

```
from optparse import OptionParser
...
def main():
    usage = "usage: %prog [options] arg"
    parser = OptionParser(usage)
    parser.add_option("-f", "--file", dest="filename",
                      help="read data from FILENAME")
    parser.add_option("-v", "--verbose",
                      action="store_true", dest="verbose")
    parser.add_option("-q", "--quiet",
```

```

        action="store_false", dest="verbose")
    ...
    (options, args) = parser.parse_args()
    if len(args) != 1:
        parser.error("incorrect number of arguments")
    if options.verbose:
        print("reading %s..." % options.filename)
    ...

if __name__ == "__main__":
    main()

```

## Reference Guide

### Creating the parser

The first step in using **optparse** is to create an `OptionParser` instance.

```
class optparse.OptionParser(...)
```

The `OptionParser` constructor has no required arguments, but a number of optional keyword arguments. You should always pass them as keyword arguments, i.e. do not rely on the order in which the arguments are declared.

```
usage (default: "%prog [options]")
```

The usage summary to print when your program is run incorrectly or with a help option. When **optparse** prints the usage string, it expands `%prog` to `os.path.basename(sys.argv[0])` (or to `prog` if you passed that keyword argument). To suppress a usage message, pass the special value **`optparse.SUPPRESS_USAGE`**.

```
option_list (default: [])
```

A list of `Option` objects to populate the parser with. The options in `option_list` are added after any options in `standard_option_list` (a class attribute that may be set by `OptionParser` subclasses), but before any

version or help options. Deprecated; use `add_option()` after creating the parser instead.

`option_class` (default: `optparse.Option`)  
Class to use when adding options to the parser in `add_option()`.

`version` (default: `None`)  
A version string to print when the user supplies a version option. If you supply a true value for `version`, `optparse` automatically adds a version option with the single option string `--version`. The substring `%prog` is expanded the same as for `usage`.

`conflict_handler` (default: `"error"`)  
Specifies what to do when options with conflicting option strings are added to the parser; see section [Conflicts between options](#).

`description` (default: `None`)  
A paragraph of text giving a brief overview of your program. `optparse` reformats this paragraph to fit the current terminal width and prints it when the user requests help (after `usage`, but before the list of options).

`formatter` (default: a new `IndentedHelpFormatter`)  
An instance of `optparse.HelpFormatter` that will be used for printing help text. `optparse` provides two concrete classes for this purpose: `IndentedHelpFormatter` and `TitledHelpFormatter`.

`add_help_option` (default: `True`)  
If true, `optparse` will add a help option (with option strings `-h` and `--help`) to the parser.

`prog`  
The string to use when expanding `%prog` in `usage` and `version` instead of `os.path.basename(sys.argv[0])`.

epilog (default: None)

A paragraph of help text to print after the option help.

## Populating the parser

There are several ways to populate the parser with options. The preferred way is by using `OptionParser.add_option()`, as shown in section [Tutorial](#). `add_option()` can be called in one of two ways:

- pass it an Option instance (as returned by `make_option()`)
- pass it any combination of positional and keyword arguments that are acceptable to `make_option()` (i.e., to the Option constructor), and it will create the Option instance for you

The other alternative is to pass a list of pre-constructed Option instances to the OptionParser constructor, as in:

```
option_list = [  
    make_option("-f", "--filename",  
                action="store", type="string", dest="fil  
    make_option("-q", "--quiet",  
                action="store_false", dest="verbose"),  
]  
parser = OptionParser(option_list=option_list)
```

(`make_option()` is a factory function for creating Option instances; currently it is an alias for the Option constructor. A future version of `optparse` may split Option into several classes, and `make_option()` will pick the right class to instantiate. Do not instantiate Option directly.)

## Defining options

Each Option instance represents a set of synonymous command-line option strings, e.g. `-f` and `--file`. You can specify any number of short or long option strings, but you must specify at least one overall option string.

The canonical way to create an `Option` instance is with the

`add_option()` method of `OptionParser`.

`OptionParser.add_option(option)`

`OptionParser.add_option(*opt_str, attr=value, ...)`

To define an option with only a short option string:

```
parser.add_option("-f", attr=value, ...)
```

And to define an option with only a long option string:

```
parser.add_option("--foo", attr=value, ...)
```

The keyword arguments define attributes of the new `Option` object. The most important option attribute is `action`, and it largely determines which other attributes are relevant or required. If you pass irrelevant option attributes, or fail to pass required ones, `optparse` raises an `OptionError` exception explaining your mistake.

An option's *action* determines what `optparse` does when it encounters this option on the command-line. The standard option actions hard-coded into `optparse` are:

`"store"`

store this option's argument (default)

`"store_const"`

store a constant value, pre-set via `Option.const`

`"store_true"`

store `True`

`"store_false"`

store `False`

`"append"`

append this option's argument to a list

`"append_const"`

append a constant value to a list, pre-set via  
`Option.const`

"count"  
    increment a counter by one

"callback"  
    call a specified function

"help"  
    print a usage message including all options and the  
    documentation for them

(If you don't supply an action, the default is "store". For this action, you may also supply **type** and **dest** option attributes; see [Standard option actions](#).)

As you can see, most actions involve storing or updating a value somewhere. **optparse** always creates a special object for this, conventionally called `options`, which is an instance of **`optparse.Values`**.

*class* `optparse.Values`

An object holding parsed argument names and values as attributes. Normally created by calling `when calling OptionParser.parse_args()`, and can be overridden by a custom subclass passed to the *values* argument of **`OptionParser.parse_args()`** (as described in [Parsing arguments](#)).

Option arguments (and various other values) are stored as attributes of this object, according to the **dest** (destination) option attribute.

For example, when you call

```
parser.parse_args()
```

one of the first things **optparse** does is create the `options` object:

```
options = Values()
```

If one of the options in this parser is defined with

```
parser.add_option("-f", "--file", action="store", type="
```

and the command-line being parsed includes any of the following:

```
-ffoo  
-f foo  
--file=foo  
--file foo
```

then `optparse`, on seeing this option, will do the equivalent of

```
options.filename = "foo"
```

The `type` and `dest` option attributes are almost as important as `action`, but `action` is the only one that makes sense for *all* options.

## Option attributes

*class* `optparse.Option`

A single command line argument, with various attributes passed by keyword to the constructor. Normally created with `OptionParser.add_option()` rather than directly, and can be overridden by a custom class via the *option\_class* argument to `OptionParser`.

The following option attributes may be passed as keyword arguments to `OptionParser.add_option()`. If you pass an option attribute that is not relevant to a particular option, or fail to pass a required option attribute, `optparse` raises `OptionError`.

`Option.action`

(default: "store")

Determines `optparse`'s behaviour when this option is seen on the command line; the available options are documented [here](#).

`Option.type`

(default: "string")

The argument type expected by this option (e.g., "string" or "int"); the available option types are documented [here](#).

#### Option.dest

(default: derived from option strings)

If the option's action implies writing or modifying a value somewhere, this tells `optparse` where to write it: `dest` names an attribute of the `options` object that `optparse` builds as it parses the command line.

#### Option.default

The value to use for this option's destination if the option is not seen on the command line. See also `OptionParser.set_defaults()`.

#### Option.nargs

(default: 1)

How many arguments of type `type` should be consumed when this option is seen. If  $> 1$ , `optparse` will store a tuple of values to `dest`.

#### Option.const

For actions that store a constant value, the constant value to store.

#### Option.choices

For options of type "choice", the list of strings the user may choose from.

#### Option.callback

For options with action "callback", the callable to call when this option is seen. See section [Option Callbacks](#) for detail on the arguments passed to the callable.

#### Option.callback\_args

#### Option.callback\_kwargs

Additional positional and keyword arguments to pass to `callback` after the four standard callback arguments.

### Option.help

Help text to print for this option when listing all available options after the user supplies a `help` option (such as `--help`). If no help text is supplied, the option will be listed without help text. To hide this option, use the special value `optparse.SUPPRESS_HELP`.

### Option.metavar

(default: derived from option strings)

Stand-in for the option argument(s) to use when printing help text. See section [Tutorial](#) for an example.

## Standard option actions

The various option actions all have slightly different requirements and effects. Most actions have several relevant option attributes which you may specify to guide `optparse`'s behaviour; a few have required attributes, which you must specify for any option using that action.

- "store" [relevant: `type`, `dest`, `nargs`, `choices`]

The option must be followed by an argument, which is converted to a value according to `type` and stored in `dest`. If `nargs > 1`, multiple arguments will be consumed from the command line; all will be converted according to `type` and stored to `dest` as a tuple. See the [Standard option types](#) section.

If `choices` is supplied (a list or tuple of strings), the type defaults to "choice".

If `type` is not supplied, it defaults to "string".

If `dest` is not supplied, `optparse` derives a destination from the first long option string (e.g., `--foo-bar` implies

foo\_bar). If there are no long option strings, **optparse** derives a destination from the first short option string (e.g., -f implies f).

Example:

```
parser.add_option("-f")
parser.add_option("-p", type="float", nargs=3, dest="point")
```

As it parses the command line

```
-f foo.txt -p 1 -3.5 4 -fbar.txt
```

**optparse** will set

```
options.f = "foo.txt"
options.point = (1.0, -3.5, 4.0)
options.f = "bar.txt"
```

- "store\_const" [required: **const**; relevant: **dest**]

The value **const** is stored in **dest**.

Example:

```
parser.add_option("-q", "--quiet",
                  action="store_const", const=0, dest="quiet")
parser.add_option("-v", "--verbose",
                  action="store_const", const=1, dest="verbose")
parser.add_option("--noisy",
                  action="store_const", const=2, dest="noisy")
```

If --noisy is seen, **optparse** will set

```
options.verbose = 2
```

- "store\_true" [relevant: **dest**]

A special case of "store\_const" that stores True to **dest**.

- "store\_false" [relevant: **dest**]

Like "store\_true", but stores False.

Example:

```
parser.add_option("--clobber", action="store_true",
parser.add_option("--no-clobber", action="store_false",
```

- "append" [relevant: **type**, **dest**, **nargs**, **choices**]

The option must be followed by an argument, which is appended to the list in **dest**. If no default value for **dest** is supplied, an empty list is automatically created when **optparse** first encounters this option on the command-line. If **nargs** > 1, multiple arguments are consumed, and a tuple of length **nargs** is appended to **dest**.

The defaults for **type** and **dest** are the same as for the "store" action.

Example:

```
parser.add_option("-t", "--tracks", action="append"
```

If `-t3` is seen on the command-line, **optparse** does the equivalent of:

```
options.tracks = []
options.tracks.append(int("3"))
```

If, a little later on, `--tracks=4` is seen, it does:

```
options.tracks.append(int("4"))
```

The `append` action calls the `append` method on the current value of the option. This means that any default value specified must have an `append` method. It also means that if the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values:

```
>>> parser.add_option("--files", action="append", d
>>> opts, args = parser.parse_args(['--files', 'ove
```

```
>>> opts.files  
['~/mypkg/defaults', 'overrides.mypkg']
```

- "append\_const" [required: `const`; relevant: `dest`]

Like "store\_const", but the value `const` is appended to `dest`; as with "append", `dest` defaults to `None`, and an empty list is automatically created the first time the option is encountered.

- "count" [relevant: `dest`]

Increment the integer stored at `dest`. If no default value is supplied, `dest` is set to zero before being incremented the first time.

Example:

```
parser.add_option("-v", action="count", dest="verbosity")
```

The first time `-v` is seen on the command line, `optparse` does the equivalent of:

```
options.verbosity = 0  
options.verbosity += 1
```

Every subsequent occurrence of `-v` results in

```
options.verbosity += 1
```

- "callback" [required: `callback`; relevant: `type`, `nargs`, `callback_args`, `callback_kwargs`]

Call the function specified by `callback`, which is called as

```
func(option, opt_str, value, parser, *args, **kwargs)
```

See section [Option Callbacks](#) for more detail.

- "help"

Prints a complete help message for all the options in the

current option parser. The help message is constructed from the `usage` string passed to `OptionParser`'s constructor and the `help` string passed to every option.

If no `help` string is supplied for an option, it will still be listed in the help message. To omit an option entirely, use the special value `optparse.SUPPRESS_HELP`.

`optparse` automatically adds a `help` option to all `OptionParsers`, so you do not normally need to create one.

Example:

```
from optparse import OptionParser, SUPPRESS_HELP

# usually, a help option is added automatically, but
# be suppressed using the add_help_option argument
parser = OptionParser(add_help_option=False)

parser.add_option("-h", "--help", action="help")
parser.add_option("-v", action="store_true", dest="verbose",
                  help="Be moderately verbose")
parser.add_option("--file", dest="filename",
                  help="Input file to read data from")
parser.add_option("--secret", help=SUPPRESS_HELP)
```

If `optparse` sees either `-h` or `--help` on the command line, it will print something like the following help message to `stdout` (assuming `sys.argv[0]` is `"foo.py"`):

```
Usage: foo.py [options]
```

Options:

<code>-h, --help</code>	Show this help message and exit
<code>-v</code>	Be moderately verbose
<code>--file=FILENAME</code>	Input file to read data from

After printing the help message, `optparse` terminates your process with `sys.exit(0)`.

- `"version"`

Prints the version number supplied to the `OptionParser` to `stdout` and exits. The version number is actually formatted and printed by the `print_version()` method of `OptionParser`. Generally only relevant if the `version` argument is supplied to the `OptionParser` constructor. As with [help](#) options, you will rarely create `version` options, since [optparse](#) automatically adds them when needed.

## Standard option types

[optparse](#) has five built-in option types: `"string"`, `"int"`, `"choice"`, `"float"` and `"complex"`. If you need to add new option types, see section [Extending optparse](#).

Arguments to string options are not checked or converted in any way: the text on the command line is stored in the destination (or passed to the callback) as-is.

Integer arguments (type `"int"`) are parsed as follows:

- if the number starts with `0x`, it is parsed as a hexadecimal number
- if the number starts with `0`, it is parsed as an octal number
- if the number starts with `0b`, it is parsed as a binary number
- otherwise, the number is parsed as a decimal number

The conversion is done by calling [int\(\)](#) with the appropriate base (2, 8, 10, or 16). If this fails, so will [optparse](#), although with a more useful error message.

`"float"` and `"complex"` option arguments are converted directly with [float\(\)](#) and [complex\(\)](#), with similar error-handling.

`"choice"` options are a subtype of `"string"` options. The [choices](#) option attribute (a sequence of strings) defines the set of allowed option arguments. [optparse.check\\_choice\(\)](#) compares user-supplied option arguments against this master list and raises [OptionValueError](#) if an invalid string is given.

## Parsing arguments

The whole point of creating and populating an `OptionParser` is to call its `parse_args()` method.

`OptionParser.parse_args(args=None, values=None)`

Parse the command-line options found in *args*.

The input parameters are

*args*

the list of arguments to process (default: `sys.argv[1:]`)

*values*

an **Values** object to store option arguments in (default: a new instance of **Values**) – if you give an existing object, the option defaults will not be initialized on it

and the return value is a pair (*options*, *args*) where

*options*

the same object that was passed in as *values*, or the `optparse.Values` instance created by **optparse**

*args*

the leftover positional arguments after all options have been processed

The most common usage is to supply neither keyword argument. If you supply *values*, it will be modified with repeated **setattr()** calls (roughly one for every option argument stored to an option destination) and returned by **parse\_args()**.

If **parse\_args()** encounters any errors in the argument list, it calls the `OptionParser`'s **error()** method with an appropriate end-user error message. This ultimately terminates your process with an exit status of 2 (the traditional Unix exit status for command-line errors).

## Querying and manipulating your option parser

The default behavior of the option parser can be customized slightly, and you can also poke around your option parser and see what's there. `OptionParser` provides several methods to help you out:

#### `OptionParser.disable_interspersed_args()`

Set parsing to stop on the first non-option. For example, if `-a` and `-b` are both simple options that take no arguments, **optparse** normally accepts this syntax:

```
prog -a arg1 -b arg2
```

and treats it as equivalent to

```
prog -a -b arg1 arg2
```

To disable this feature, call **disable\_interspersed\_args()**. This restores traditional Unix syntax, where option parsing stops with the first non-option argument.

Use this if you have a command processor which runs another command which has options of its own and you want to make sure these options don't get confused. For example, each command might have a different set of options.

#### `OptionParser.enable_interspersed_args()`

Set parsing to not stop on the first non-option, allowing interspersing switches with command arguments. This is the default behavior.

#### `OptionParser.get_option(opt_str)`

Returns the `Option` instance with the option string `opt_str`, or `None` if no options have that option string.

#### `OptionParser.has_option(opt_str)`

Return `True` if the `OptionParser` has an option with option string `opt_str` (e.g., `-q` or `--verbose`).

`OptionParser.remove_option(opt_str)`

If the `OptionParser` has an option corresponding to *opt\_str*, that option is removed. If that option provided any other option strings, all of those option strings become invalid. If *opt\_str* does not occur in any option belonging to this `OptionParser`, raises `ValueError`.

## Conflicts between options

If you're not careful, it's easy to define options with conflicting option strings:

```
parser.add_option("-n", "--dry-run", ...)
...
parser.add_option("-n", "--noisy", ...)
```

(This is particularly true if you've defined your own `OptionParser` subclass with some standard options.)

Every time you add an option, `optparse` checks for conflicts with existing options. If it finds any, it invokes the current conflict-handling mechanism. You can set the conflict-handling mechanism either in the constructor:

```
parser = OptionParser(..., conflict_handler=handler)
```

or with a separate call:

```
parser.set_conflict_handler(handler)
```

The available conflict handlers are:

- "error" (default)

  - assume option conflicts are a programming error and raise `OptionConflictError`

- "resolve"

  - resolve option conflicts intelligently (see below)

As an example, let's define an `OptionParser` that resolves conflicts intelligently and add conflicting options to it:

```
parser = OptionParser(conflict_handler="resolve")
parser.add_option("-n", "--dry-run", ..., help="do no harm")
parser.add_option("-n", "--noisy", ..., help="be noisy")
```

At this point, `optparse` detects that a previously added option is already using the `-n` option string. Since `conflict_handler` is `"resolve"`, it resolves the situation by removing `-n` from the earlier option's list of option strings. Now `--dry-run` is the only way for the user to activate that option. If the user asks for help, the help message will reflect that:

```
Options:
  --dry-run      do no harm
  ...
  -n, --noisy    be noisy
```

It's possible to whittle away the option strings for a previously added option until there are none left, and the user has no way of invoking that option from the command-line. In that case, `optparse` removes that option completely, so it doesn't show up in help text or anywhere else. Carrying on with our existing `OptionParser`:

```
parser.add_option("--dry-run", ..., help="new dry-run option")
```

At this point, the original `-n/--dry-run` option is no longer accessible, so `optparse` removes it, leaving this help text:

```
Options:
  ...
  -n, --noisy    be noisy
  --dry-run      new dry-run option
```

## Cleanup

`OptionParser` instances have several cyclic references. This should not be a problem for Python's garbage collector, but you may wish to break the cyclic references explicitly by calling `destroy()` on

your `OptionParser` once you are done with it. This is particularly useful in long-running applications where large object graphs are reachable from your `OptionParser`.

## Other methods

`OptionParser` supports several other public methods:

`OptionParser.set_usage(usage)`

Set the usage string according to the rules described above for the `usage` constructor keyword argument. Passing `None` sets the default usage string; use **`optparse.SUPPRESS_USAGE`** to suppress a usage message.

`OptionParser.print_usage(file = None)`

Print the usage message for the current program (`self.usage`) to *file* (default `stdout`). Any occurrence of the string `%prog` in `self.usage` is replaced with the name of the current program. Does nothing if `self.usage` is empty or not defined.

`OptionParser.get_usage()`

Same as **`print_usage()`** but returns the usage string instead of printing it.

`OptionParser.set_defaults(dest = value, ...)`

Set default values for several option destinations at once. Using **`set_defaults()`** is the preferred way to set default values for options, since multiple options can share the same destination. For example, if several “mode” options all set the same destination, any one of them can set the default, and the last one wins:

```
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced",
                  default="novice")      # overridden
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice",
```

```
default="advanced") # overrides
```

To avoid this confusion, use `set_defaults()`:

```
parser.set_defaults(mode="advanced")
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced")
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice")
```

## Option Callbacks

When `optparse`'s built-in actions and types aren't quite enough for your needs, you have two choices: extend `optparse` or define a callback option. Extending `optparse` is more general, but overkill for a lot of simple cases. Quite often a simple callback is all you need.

There are two steps to defining a callback option:

- define the option itself using the "callback" action
- write the callback; this is a function (or method) that takes at least four arguments, as described below

### Defining a callback option

As always, the easiest way to define a callback option is by using the `OptionParser.add_option()` method. Apart from `action`, the only option attribute you must specify is `callback`, the function to call:

```
parser.add_option("-c", action="callback", callback=my_callback)
```

`callback` is a function (or other callable object), so you must have already defined `my_callback()` when you create this callback option. In this simple case, `optparse` doesn't even know if `-c` takes any arguments, which usually means that the option takes no arguments—the mere presence of `-c` on the command-line is all it needs to know. In some circumstances, though, you might want your callback to consume an arbitrary number of command-line

arguments. This is where writing callbacks gets tricky; it's covered later in this section.

`optparse` always passes four particular arguments to your callback, and it will only pass additional arguments if you specify them via `callback_args` and `callback_kwargs`. Thus, the minimal callback function signature is:

```
def my_callback(option, opt, value, parser):
```

The four arguments to a callback are described below.

There are several other option attributes that you can supply when you define a callback option:

#### `type`

has its usual meaning: as with the "store" or "append" actions, it instructs `optparse` to consume one argument and convert it to `type`. Rather than storing the converted value(s) anywhere, though, `optparse` passes it to your callback function.

#### `nargs`

also has its usual meaning: if it is supplied and  $> 1$ , `optparse` will consume `nargs` arguments, each of which must be convertible to `type`. It then passes a tuple of converted values to your callback.

#### `callback_args`

a tuple of extra positional arguments to pass to the callback

#### `callback_kwargs`

a dictionary of extra keyword arguments to pass to the callback

## How callbacks are called

All callbacks are called as follows:

```
func(option, opt_str, value, parser, *args, **kwargs)
```

where

`option`

is the `Option` instance that's calling the callback

`opt_str`

is the option string seen on the command-line that's triggering the callback. (If an abbreviated long option was used, `opt_str` will be the full, canonical option string—e.g. if the user puts `--foo` on the command-line as an abbreviation for `--foobar`, then `opt_str` will be `"--foobar"`.)

`value`

is the argument to this option seen on the command-line. `optparse` will only expect an argument if `type` is set; the type of `value` will be the type implied by the option's type. If `type` for this option is `None` (no argument expected), then `value` will be `None`. If `nargs` > 1, `value` will be a tuple of values of the appropriate type.

`parser`

is the `OptionParser` instance driving the whole thing, mainly useful because you can access some other interesting data through its instance attributes:

`parser.largs`

the current list of leftover arguments, ie. arguments that have been consumed but are neither options nor option arguments. Feel free to modify `parser.largs`, e.g. by adding more arguments to it. (This list will become `args`, the second return value of `parse_args()`.)

`parser.rargs`

the current list of remaining arguments, ie. with `opt_str` and `value` (if applicable) removed, and only the arguments following them still there. Feel free to modify `parser.rargs`, e.g. by consuming more arguments.

`parser.values`

the object where option values are by default stored (an instance of `optparse.OptionValues`). This lets callbacks use the same mechanism as the rest of `optparse` for storing option values; you don't need to mess around with globals or closures. You can also access or modify the value(s) of any options already encountered on the command-line.

`args`

is a tuple of arbitrary positional arguments supplied via the `callback_args` option attribute.

`kwargs`

is a dictionary of arbitrary keyword arguments supplied via `callback_kwargs`.

## Raising errors in a callback

The callback function should raise `OptionValueError` if there are any problems with the option or its argument(s). `optparse` catches this and terminates the program, printing the error message you supply to stderr. Your message should be clear, concise, accurate, and mention the option at fault. Otherwise, the user will have a hard time figuring out what they did wrong.

## Callback example 1: trivial callback

Here's an example of a callback option that takes no arguments, and simply records that the option was seen:

```
def record_foo_seen(option, opt_str, value, parser):  
    parser.values.saw_foo = True
```

```
parser.add_option("--foo", action="callback", callback=record_foo_seen)
```

Of course, you could do that with the `"store_true"` action.

## Callback example 2: check option order

Here's a slightly more interesting example: record the fact that `-a` is seen, but blow up if it comes after `-b` in the command-line.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use -a after -b")
    parser.values.a = 1
...
parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
```

### Callback example 3: check option order (generalized)

If you want to re-use this callback for several similar options (set a flag, but blow up if `-b` has already been seen), it needs a bit of work: the error message and the flag that it sets must be generalized.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use %s after -b" % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
parser.add_option("-c", action="callback", callback=check_order)
```

### Callback example 4: check arbitrary condition

Of course, you could put any condition in there—you're not limited to checking the values of already-defined options. For example, if you have options that should not be called when the moon is full, all you have to do is this:

```
def check_moon(option, opt_str, value, parser):
    if is_moon_full():
        raise OptionValueError("%s option invalid when moon is full"
                                % opt_str)
    setattr(parser.values, option.dest, 1)
```

```
...
parser.add_option("--foo",
                  action="callback", callback=check_moon
```

(The definition of `is_moon_full()` is left as an exercise for the reader.)

## Callback example 5: fixed arguments

Things get slightly more interesting when you define callback options that take a fixed number of arguments. Specifying that a callback option takes arguments is similar to defining a "store" or "append" option: if you define `type`, then the option takes one argument that must be convertible to that type; if you further define `nargs`, then the option takes `nargs` arguments.

Here's an example that just emulates the standard "store" action:

```
def store_value(option, opt_str, value, parser):
    setattr(parser.values, option.dest, value)
...
parser.add_option("--foo",
                  action="callback", callback=store_value,
                  type="int", nargs=3, dest="foo")
```

Note that `optparse` takes care of consuming 3 arguments and converting them to integers for you; all you have to do is store them. (Or whatever; obviously you don't need a callback for this example.)

## Callback example 6: variable arguments

Things get hairy when you want an option to take a variable number of arguments. For this case, you must write a callback, as `optparse` doesn't provide any built-in capabilities for it. And you have to deal with certain intricacies of conventional Unix command-line parsing that `optparse` normally handles for you. In particular, callbacks should implement the conventional rules for bare `--` and `-` arguments:

- either `--` or `-` can be option arguments
- bare `--` (if not the argument to some option): halt command-line processing and discard the `--`
- bare `-` (if not the argument to some option): halt command-line processing but keep the `-` (append it to `parser.largs`)

If you want an option that takes a variable number of arguments, there are several subtle, tricky issues to worry about. The exact implementation you choose will be based on which trade-offs you're willing to make for your application (which is why `optparse` doesn't support this sort of thing directly).

Nevertheless, here's a stab at a callback for an option with variable arguments:

```
def vararg_callback(option, opt_str, value, parser):
    assert value is None
    value = []

    def floatable(str):
        try:
            float(str)
            return True
        except ValueError:
            return False

    for arg in parser.rargs:
        # stop on --foo like options
        if arg[:2] == "--" and len(arg) > 2:
            break
        # stop on -a, but not on -3 or -3.0
        if arg[:1] == "-" and len(arg) > 1 and not floatable(arg):
            break
        value.append(arg)

    del parser.rargs[:len(value)]
    setattr(parser.values, option.dest, value)
```

```
...
parser.add_option("-c", "--callback", dest="vararg_attr",
                  action="callback", callback=vararg_cal
```

## Extending `optparse`

Since the two major controlling factors in how `optparse` interprets command-line options are the action and type of each option, the most likely direction of extension is to add new actions and new types.

### Adding new types

To add new types, you need to define your own subclass of `optparse`'s `Option` class. This class has a couple of attributes that define `optparse`'s types: `TYPES` and `TYPE_CHECKER`.

#### `Option.TYPES`

A tuple of type names; in your subclass, simply define a new tuple `TYPES` that builds on the standard one.

#### `Option.TYPE_CHECKER`

A dictionary mapping type names to type-checking functions. A type-checking function has the following signature:

```
def check_mytype(option, opt, value)
```

where `option` is an `Option` instance, `opt` is an option string (e.g., `-f`), and `value` is the string from the command line that must be checked and converted to your desired type. `check_mytype()` should return an object of the hypothetical type `mytype`. The value returned by a type-checking function will wind up in the `OptionValues` instance returned by `OptionParser.parse_args()`, or be passed to a callback as the `value` parameter.

Your type-checking function should raise `OptionValueError` if it encounters any problems. `OptionValueError` takes a single string argument, which is

passed as-is to `OptionParser`'s `error()` method, which in turn prepends the program name and the string "error:" and prints everything to stderr before terminating the process.

Here's a silly example that demonstrates adding a "complex" option type to parse Python-style complex numbers on the command line. (This is even sillier than it used to be, because `optparse` 1.3 added built-in support for complex numbers, but never mind.)

First, the necessary imports:

```
from copy import copy
from optparse import Option, OptionValueError
```

You need to define your type-checker first, since it's referred to later (in the `TYPE_CHECKER` class attribute of your `Option` subclass):

```
def check_complex(option, opt, value):
    try:
        return complex(value)
    except ValueError:
        raise OptionValueError(
            "option %s: invalid complex value: %r" % (opt, value))
```

Finally, the `Option` subclass:

```
class MyOption (Option):
    TYPES = Option.TYPES + ("complex",)
    TYPE_CHECKER = copy(Option.TYPE_CHECKER)
    TYPE_CHECKER["complex"] = check_complex
```

(If we didn't make a `copy()` of `Option.TYPE_CHECKER`, we would end up modifying the `TYPE_CHECKER` attribute of `optparse`'s `Option` class. This being Python, nothing stops you from doing that except good manners and common sense.)

That's it! Now you can write a script that uses the new option type just like any other `optparse`-based script, except you have to

instruct your `OptionParser` to use `MyOption` instead of `Option`:

```
parser = OptionParser(option_class=MyOption)
parser.add_option("-c", type="complex")
```

Alternately, you can build your own option list and pass it to `OptionParser`; if you don't use `add_option()` in the above way, you don't need to tell `OptionParser` which option class to use:

```
option_list = [MyOption("-c", action="store", type="complex")]
parser = OptionParser(option_list=option_list)
```

## Adding new actions

Adding new actions is a bit trickier, because you have to understand that `optparse` has a couple of classifications for actions:

“store” actions

actions that result in `optparse` storing a value to an attribute of the current `OptionValues` instance; these options require a `dest` attribute to be supplied to the `Option` constructor.

“typed” actions

actions that take a value from the command line and expect it to be of a certain type; or rather, a string that can be converted to a certain type. These options require a `type` attribute to the `Option` constructor.

These are overlapping sets: some default “store” actions are `"store"`, `"store_const"`, `"append"`, and `"count"`, while the default “typed” actions are `"store"`, `"append"`, and `"callback"`.

When you add an action, you need to categorize it by listing it in at least one of the following class attributes of `Option` (all are lists of strings):

`Option.ACTIONS`

All actions must be listed in `ACTIONS`.

## Option.STORE\_ACTIONS

“store” actions are additionally listed here.

## Option.TYPED\_ACTIONS

“typed” actions are additionally listed here.

## Option.ALWAYS\_TYPED\_ACTIONS

Actions that always take a type (i.e. whose options always take a value) are additionally listed here. The only effect of this is that `optparse` assigns the default type, “string”, to options with no explicit type whose action is listed in `ALWAYS_TYPED_ACTIONS`.

In order to actually implement your new action, you must override Option’s `take_action()` method and add a case that recognizes your action.

For example, let’s add an “extend” action. This is similar to the standard “append” action, but instead of taking a single value from the command-line and appending it to an existing list, “extend” will take multiple values in a single comma-delimited string, and extend an existing list with them. That is, if `--names` is an “extend” option of type “string”, the command line

```
--names=foo,bar --names blah --names ding,dong
```

would result in a list

```
["foo", "bar", "blah", "ding", "dong"]
```

Again we define a subclass of Option:

```
class MyOption(Option):
```

```
    ACTIONS = Option.ACTIONS + ("extend",)
```

```
    STORE_ACTIONS = Option.STORE_ACTIONS + ("extend",)
```

```
    TYPED_ACTIONS = Option.TYPED_ACTIONS + ("extend",)
```

```
    ALWAYS_TYPED_ACTIONS = Option.ALWAYS_TYPED_ACTIONS +
```

```

def take_action(self, action, dest, opt, value, values):
    if action == "extend":
        lvalue = value.split(",")
        values.ensure_value(dest, []).extend(lvalue)
    else:
        Option.take_action(
            self, action, dest, opt, value, values,

```

Features of note:

- "extend" both expects a value on the command-line and stores that value somewhere, so it goes in both **STORE\_ACTIONS** and **TYPED\_ACTIONS**.
- to ensure that **optparse** assigns the default type of "string" to "extend" actions, we put the "extend" action in **ALWAYS\_TYPED\_ACTIONS** as well.
- **MyOption.take\_action()** implements just this one new action, and passes control back to **Option.take\_action()** for the standard **optparse** actions.
- **values** is an instance of the **optparse\_parser.Values** class, which provides the very useful **ensure\_value()** method. **ensure\_value()** is essentially **getattr()** with a safety valve; it is called as

```
values.ensure_value(attr, value)
```

If the **attr** attribute of **values** doesn't exist or is **None**, then **ensure\_value()** first sets it to **value**, and then returns **value**. This is very handy for actions like "extend", "append", and "count", all of which accumulate data in a variable and expect that variable to be of a certain type (a list for the first two, an integer for the latter). Using **ensure\_value()** means that scripts using your action don't have to worry about setting a default value for the option destinations in question; they can just leave the default as **None** and **ensure\_value()** will take care of getting it right when it's needed.

# Exceptions

*exception* optparse.OptionError

Raised if an **Option** instance is created with invalid or inconsistent arguments.

*exception* optparse.OptionConflictError

Raised if conflicting options are added to an **OptionParser**.

*exception* optparse.OptionValueError

Raised if an invalid option value is encountered on the command line.

*exception* optparse.BadOptionError

Raised if an invalid option is passed on the command line.

*exception* optparse.AmbiguousOptionError

Raised if an ambiguous option is passed on the command line.

# ossaudiodev — Access to OSS-compatible audio devices

*Deprecated since version 3.11, will be removed in version 3.13:* The **ossaudiodev** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#ossaudiodev) [https://peps.python.org/pep-0594/#ossaudiodev] for details).

---

This module allows you to access the OSS (Open Sound System) audio interface. OSS is available for a wide range of open-source and commercial Unices, and is the standard audio interface for Linux and recent versions of FreeBSD.

*Changed in version 3.3:* Operations in this module now raise **OSError** where **IOError** was raised.

## See also

**Open Sound System Programmer's Guide** [<http://www.opensound.com/pguide/oss.pdf>]  
the official documentation for the OSS C API

The module defines a large number of constants supplied by the OSS device driver; see `<sys/soundcard.h>` on either Linux or FreeBSD for a listing.

**ossaudiodev** defines the following variables and functions:

*exception* **ossaudiodev.OSSAudioError**

This exception is raised on certain errors. The argument is a string describing what went wrong.

(If **ossaudiodev** receives an error from a system call such as **open()**, **write()**, or **ioctl()**, it raises **OSError**. Errors detected directly by **ossaudiodev** result in

`OSSAudioError`.)

(For backwards compatibility, the exception class is also available as `ossaudiodev.error`.)

`ossaudiodev.open(mode)`

`ossaudiodev.open(device, mode)`

Open an audio device and return an OSS audio device object. This object supports many file-like methods, such as `read()`, `write()`, and `fileno()` (although there are subtle differences between conventional Unix read/write semantics and those of OSS audio devices). It also supports a number of audio-specific methods; see below for the complete list of methods.

*device* is the audio device filename to use. If it is not specified, this module first looks in the environment variable **AUDIODEV** for a device to use. If not found, it falls back to `/dev/dsp`.

*mode* is one of `'r'` for read-only (record) access, `'w'` for write-only (playback) access and `'rw'` for both. Since many sound cards only allow one process to have the recorder or player open at a time, it is a good idea to open the device only for the activity needed. Further, some sound cards are half-duplex: they can be opened for reading or writing, but not both at once.

Note the unusual calling syntax: the *first* argument is optional, and the second is required. This is a historical artifact for compatibility with the older **linuxaudiodev** module which **ossaudiodev** supersedes.

`ossaudiodev.openmixer([device])`

Open a mixer device and return an OSS mixer device object. *device* is the mixer device filename to use. If it is not specified, this module first looks in the environment variable **MIXERDEV** for a device to use. If not found, it falls back to `/dev/mixer`.

# Audio Device Objects

Before you can write to or read from an audio device, you must call three methods in the correct order:

1. **setfmt()** to set the output format
2. **channels()** to set the number of channels
3. **speed()** to set the sample rate

Alternately, you can use the **setparameters()** method to set all three audio parameters at once. This is more convenient, but may not be as flexible in all cases.

The audio device objects returned by **open()** define the following methods and (read-only) attributes:

`oss_audio_device.close()`

Explicitly close the audio device. When you are done writing to or reading from an audio device, you should explicitly close it. A closed device cannot be used again.

`oss_audio_device.fileno()`

Return the file descriptor associated with the device.

`oss_audio_device.read(size)`

Read *size* bytes from the audio input and return them as a Python string. Unlike most Unix device drivers, OSS audio devices in blocking mode (the default) will block **read()** until the entire requested amount of data is available.

`oss_audio_device.write(data)`

Write a **bytes-like object** *data* to the audio device and return the number of bytes written. If the audio device is in blocking mode (the default), the entire data is always written (again, this is different from usual Unix device semantics). If the device is in non-blocking mode, some data may not be written—see **writeall()**.

*Changed in version 3.5:* Writable [bytes-like object](#) is now accepted.

`oss_audio_device.writeall(data)`

Write a [bytes-like object](#) *data* to the audio device: waits until the audio device is able to accept data, writes as much data as it will accept, and repeats until *data* has been completely written. If the device is in blocking mode (the default), this has the same effect as `write()`; `writeall()` is only useful in non-blocking mode. Has no return value, since the amount of data written is always equal to the amount of data supplied.

*Changed in version 3.5:* Writable [bytes-like object](#) is now accepted.

*Changed in version 3.2:* Audio device objects also support the context management protocol, i.e. they can be used in a `with` statement.

The following methods each map to exactly one `ioctl()` system call. The correspondence is obvious: for example, `setfmt()` corresponds to the `SNDCTL_DSP_SETFMT` `ioctl`, and `sync()` to `SNDCTL_DSP_SYNC` (this can be useful when consulting the OSS documentation). If the underlying `ioctl()` fails, they all raise [OSError](#).

`oss_audio_device.nonblock()`

Put the device into non-blocking mode. Once in non-blocking mode, there is no way to return it to blocking mode.

`oss_audio_device.getfmts()`

Return a bitmask of the audio output formats supported by the soundcard. Some of the formats supported by OSS are:

Description
<code>AFMT_U_LAW</code> encoding (used by Sun .au files and /dev/audio)
<code>AFMT_A_LAW</code> encoding
<code>AFMT_COMPRESSED</code> format defined by the Interactive

Multimedia Association

**AFMT\_U8**, 8-bit audio

**AFMT\_S16\_LE**, 16-bit audio, little-endian byte order (as used by Intel processors)

**AFMT\_S16\_BE**, 16-bit audio, big-endian byte order (as used by 68k, PowerPC, Sparc)

**AFMT\_S8**, 8-bit audio

**AFMT\_U16\_LE**, 16-bit little-endian audio

**AFMT\_U16\_BE**, 16-bit big-endian audio

Consult the OSS documentation for a full list of audio formats, and note that most devices support only a subset of these formats. Some older devices only support **AFMT\_U8**; the most common format used today is **AFMT\_S16\_LE**.

`oss_audio_device.setfmt(format)`

Try to set the current audio format to *format*—see [getfmts\(\)](#) for a list. Returns the audio format that the device was set to, which may not be the requested format. May also be used to return the current audio format—do this by passing an “audio format” of **AFMT\_QUERY**.

`oss_audio_device.channels(nchannels)`

Set the number of output channels to *nchannels*. A value of 1 indicates monophonic sound, 2 stereophonic. Some devices may have more than 2 channels, and some high-end devices may not support mono. Returns the number of channels the device was set to.

`oss_audio_device.speed(samplerate)`

Try to set the audio sampling rate to *samplerate* samples per second. Returns the rate actually set. Most sound devices don't support arbitrary sampling rates. Common rates are:

Description
8000
11025
22050
44100

### `oss_audio_device.sync()`

Wait until the sound device has played every byte in its buffer. (This happens implicitly when the device is closed.) The OSS documentation recommends closing and re-opening the device rather than using `sync()`.

### `oss_audio_device.reset()`

Immediately stop playing or recording and return the device to a state where it can accept commands. The OSS documentation recommends closing and re-opening the device after calling `reset()`.

### `oss_audio_device.post()`

Tell the driver that there is likely to be a pause in the output, making it possible for the device to handle the pause more intelligently. You might use this after playing a spot sound effect, before waiting for user input, or before doing disk I/O.

The following convenience methods combine several ioctls, or one ioctl and some simple calculations.

### `oss_audio_device.setparameters(format, nchannels, samplerate [, strict=False])`

Set the key audio sampling parameters—sample format, number of channels, and sampling rate—in one method call. *format*, *nchannels*, and *samplerate* should be as specified in the `setfmt()`, `channels()`, and `speed()` methods. If *strict* is true, `setparameters()` checks to see if each parameter was actually set to the requested value, and raises `OSSAudioError` if not. Returns a tuple (*format*, *nchannels*, *samplerate*) indicating the parameter values that were actually set by the device driver (i.e., the same as the return values of `setfmt()`, `channels()`, and `speed()`).

For example,

```
(fmt, channels, rate) = dsp.setparameters(fmt, chan
```

is equivalent to

```
fmt = dsp.setfmt(fmt)
channels = dsp.channels(channels)
rate = dsp.rate(rate)
```

`oss_audio_device.bufsize()`

Returns the size of the hardware buffer, in samples.

`oss_audio_device.obufcount()`

Returns the number of samples that are in the hardware buffer yet to be played.

`oss_audio_device.obuffree()`

Returns the number of samples that could be queued into the hardware buffer to be played without blocking.

Audio device objects also support several read-only attributes:

`oss_audio_device.closed`

Boolean indicating whether the device has been closed.

`oss_audio_device.name`

String containing the name of the device file.

`oss_audio_device.mode`

The I/O mode for the file, either `"r"`, `"rw"`, or `"w"`.

## Mixer Device Objects

The mixer object provides two file-like methods:

`oss_mixer_device.close()`

This method closes the open mixer device file. Any further attempts to use the mixer after this file is closed will raise an

## **OSError.**

`oss_mixer_device.fileno()`

Returns the file handle number of the open mixer device file.

*Changed in version 3.2:* Mixer objects also support the context management protocol.

The remaining methods are specific to audio mixing:

`oss_mixer_device.controls()`

This method returns a bitmask specifying the available mixer controls (“Control” being a specific mixable “channel”, such as **SOUND\_MIXER\_PCM** or **SOUND\_MIXER\_SYNTH**). This bitmask indicates a subset of all available mixer controls—the **SOUND\_MIXER\_\*** constants defined at module level. To determine if, for example, the current mixer object supports a PCM mixer, use the following Python code:

```
mixer=ossaudiodev.openmixer()
if mixer.controls() & (1 << ossaudiodev.SOUND_MIXER_PCM):
    # PCM is supported
    ... code ...
```

For most purposes, the **SOUND\_MIXER\_VOLUME** (master volume) and **SOUND\_MIXER\_PCM** controls should suffice—but code that uses the mixer should be flexible when it comes to choosing mixer controls. On the Gravis Ultrasound, for example, **SOUND\_MIXER\_VOLUME** does not exist.

`oss_mixer_device.stereocontrols()`

Returns a bitmask indicating stereo mixer controls. If a bit is set, the corresponding control is stereo; if it is unset, the control is either monophonic or not supported by the mixer (use in combination with `controls()` to determine which).

See the code example for the `controls()` function for an example of getting data from a bitmask.

`oss_mixer_device.reccontrols()`

Returns a bitmask specifying the mixer controls that may be used to record. See the code example for `controls()` for an example of reading from a bitmask.

`oss_mixer_device.get(control)`

Returns the volume of a given mixer control. The returned volume is a 2-tuple `(left_volume, right_volume)`. Volumes are specified as numbers from 0 (silent) to 100 (full volume). If the control is monophonic, a 2-tuple is still returned, but both volumes are the same.

Raises `OSSAudioError` if an invalid control is specified, or `OSError` if an unsupported control is specified.

`oss_mixer_device.set(control, (left, right))`

Sets the volume for a given mixer control to `(left, right)`. `left` and `right` must be ints and between 0 (silent) and 100 (full volume). On success, the new volume is returned as a 2-tuple. Note that this may not be exactly the same as the volume specified, because of the limited resolution of some soundcard's mixers.

Raises `OSSAudioError` if an invalid mixer control was specified, or if the specified volumes were out-of-range.

`oss_mixer_device.get_recsrc()`

This method returns a bitmask indicating which control(s) are currently being used as a recording source.

`oss_mixer_device.set_recsrc(bitmask)`

Call this function to specify a recording source. Returns a bitmask indicating the new recording source (or sources) if successful; raises `OSError` if an invalid source was specified. To set the current recording source to the microphone input:

```
mixer.setrecsrc (1 << ossaudiodev.SOUND_MIXER_MIC)
```

# `pipes` — Interface to shell pipelines

**Source code:** [Lib/pipes.py](https://github.com/python/cpython/tree/3.12/Lib/pipes.py) [https://github.com/python/cpython/tree/3.12/Lib/pipes.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The `pipes` module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#pipes) [https://peps.python.org/pep-0594/#pipes] for details). Please use the `subprocess` module instead.

---

The `pipes` module defines a class to abstract the concept of a *pipeline* — a sequence of converters from one file to another.

Because the module uses `/bin/sh` command lines, a POSIX or compatible shell for `os.system()` and `os.popen()` is required.

**Availability:** Unix, not VxWorks.

The `pipes` module defines the following class:

`class pipes.Template`

    An abstraction of a pipeline.

Example:

```
>>> import pipes
>>> t = pipes.Template()
>>> t.append('tr a-z A-Z', '--')
>>> f = t.open('pipefile', 'w')
>>> f.write('hello world')
>>> f.close()
>>> open('pipefile').read()
'HELLO WORLD'
```

# Template Objects

Template objects following methods:

`Template.reset()`

Restore a pipeline template to its initial state.

`Template.clone()`

Return a new, equivalent, pipeline template.

`Template.debug(flag)`

If *flag* is true, turn debugging on. Otherwise, turn debugging off. When debugging is on, commands to be executed are printed, and the shell is given `set -x` command to be more verbose.

`Template.append(cmd, kind)`

Append a new action at the end. The *cmd* variable must be a valid bourne shell command. The *kind* variable consists of two letters.

The first letter can be either of `'-'` (which means the command reads its standard input), `'f'` (which means the commands reads a given file on the command line) or `'.'` (which means the commands reads no input, and hence must be first.)

Similarly, the second letter can be either of `'-'` (which means the command writes to standard output), `'f'` (which means the command writes a file on the command line) or `'.'` (which means the command does not write anything, and hence must be last.)

`Template.prepend(cmd, kind)`

Add a new action at the beginning. See [append\(\)](#) for explanations of the arguments.

Template.open(*file*, *mode*)

Return a file-like object, open to *file*, but read from or written to by the pipeline. Note that only one of 'r', 'w' may be given.

Template.copy(*infile*, *outfile*)

Copy *infile* to *outfile* through the pipe.

# sndhdr — Determine type of sound file

**Source code:** [Lib/sndhdr.py](#) [<https://github.com/python/cpython/tree/3.12/Lib/sndhdr.py>]

*Deprecated since version 3.11, will be removed in version 3.13:* The **sndhdr** module is deprecated (see [PEP 594](#) [<https://peps.python.org/pep-0594/#sndhdr>] for details and alternatives).

---

The **sndhdr** provides utility functions which attempt to determine the type of sound data which is in a file. When these functions are able to determine what type of sound data is stored in a file, they return a **namedtuple()**, containing five attributes: (*filetype*, *framerate*, *nchannels*, *nframes*, *sampwidth*). The value for *type* indicates the data type and will be one of the strings 'aifc', 'aiff', 'au', 'hcom', 'sndr', 'sndt', 'voc', 'wav', '8svx', 'sb', 'ub', or 'ul'. The *sampling\_rate* will be either the actual value or 0 if unknown or difficult to decode. Similarly, *channels* will be either the number of channels or 0 if it cannot be determined or if the value is difficult to decode. The value for *frames* will be either the number of frames or -1. The last item in the tuple, *bits\_per\_sample*, will either be the sample size in bits or 'A' for A-LAW or 'U' for u-LAW.

**sndhdr.what(filename)**

Determines the type of sound data stored in the file *filename* using **whathdr()**. If it succeeds, returns a namedtuple as described above, otherwise `None` is returned.

*Changed in version 3.5:* Result changed from a tuple to a namedtuple.

**sndhdr.whathdr(filename)**

Determines the type of sound data stored in a file based on the file header. The name of the file is given by *filename*. This function returns a namedtuple as described above on success, or `None`.

*Changed in version 3.5:* Result changed from a tuple to a namedtuple.

The following sound header types are recognized, as listed below with the return value from `whathdr()`: and `what()`:

### **Sound header format**

---

Compressed Audio Interchange Files

---

Audio Interchange Files

---

Aiff Files

---

HC-OM Files

---

Sndtool Sound Files

---

Creative Labs Audio Files

---

Waveform Audio File Format Files

---

8-Bit Sampled Voice Files

---

Signed Byte Audio Data Files

---

U-Buffer Files

---

uLAW Audio Files

---

### **sndhdr.tests**

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When `what()` is called with a byte-stream, the file-like object will be `None`.

The test function should return a string describing the image type if the test succeeded, or `None` if it failed.

Example:

```
>>> import sndhdr
>>> imghdr.what('bass.wav')
'wav'
>>> imghdr.whathdr('bass.wav')
'wav'
```

# spwd — The shadow password database

*Deprecated since version 3.11, will be removed in version 3.13:* The **spwd** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#spwd) [https://peps.python.org/pep-0594/#spwd] for details and alternatives).

---

This module provides access to the Unix shadow password database. It is available on various Unix versions.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

You must have enough privileges to access the shadow password database (this usually means you have to be root).

Shadow password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `spwd` structure (Attribute field below, see `<shadow.h>`):

Member
<code>sp_namp</code>
<code>sp_pwdp</code>
<code>sp_lstchg</code>
<code>sp_min</code>
<code>sp_max</code>
<code>sp_warn</code>
<code>sp_inact</code>
<code>sp_expire</code>
<code>sp_reserved</code>

The `sp_namp` and `sp_pwdp` items are strings, all others are integers.

**KeyError** is raised if the entry asked for cannot be found.

The following functions are defined:

`spwd.getspnam(name)`

Return the shadow password database entry for the given user name.

*Changed in version 3.6:* Raises a **PermissionError** instead of **KeyError** if the user doesn't have privileges.

`spwd.getspall()`

Return a list of all available shadow password database entries, in arbitrary order.

**See also**

**Module** **grp**

An interface to the group database, similar to this.

**Module** **pwd**

An interface to the normal password database, similar to this.

# sunau — Read and write Sun AU files

**Source code:** [Lib/sunau.py](https://github.com/python/cpython/tree/3.12/Lib/sunau.py) [https://github.com/python/cpython/tree/3.12/Lib/sunau.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **sunau** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#sunau) [https://peps.python.org/pep-0594/#sunau] for details).

---

The **sunau** module provides a convenient interface to the Sun AU sound format. Note that this module is interface-compatible with the modules **aifc** and **wave**.

An audio file consists of a header followed by the data. The fields of the header are:

## Fields

<b>File type</b>	File type, e.g. .snd.
<b>Size of header</b>	Size of header, including info, in bytes.
<b>Physical size</b>	Physical size of the data, in bytes.
<b>Encoding</b>	Encoding how the audio samples are encoded.
<b>Sample rate</b>	Sample rate.
<b>Number of channels</b>	Number of channels in the samples.
<b>ASCII string</b>	ASCII string giving a description of the audio file (padded with null bytes).

Apart from the info field, all header fields are 4 bytes in size. They are all 32-bit unsigned integers encoded in big-endian byte order.

The **sunau** module defines the following functions:

**sunau.open(file, mode)**

If *file* is a string, open the file by that name, otherwise treat it as a seekable file-like object. *mode* can be any of

'r'

Read only mode.

'w'

Write only mode.

Note that it does not allow read/write files.

A *mode* of 'r' returns an **AU\_read** object, while a *mode* of 'w' or 'wb' returns an **AU\_write** object.

The **sunau** module defines the following exception:

*exception* sunau.Error

An error raised when something is impossible because of Sun AU specs or implementation deficiency.

The **sunau** module defines the following data items:

sunau.AUDIO\_FILE\_MAGIC

An integer every valid Sun AU file begins with, stored in big-endian form. This is the string `.snd` interpreted as an integer.

sunau.AUDIO\_FILE\_ENCODING\_MULAW\_8

sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_8

sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_16

sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_24

sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_32

sunau.AUDIO\_FILE\_ENCODING\_ALAW\_8

Values of the encoding field from the AU header which are supported by this module.

sunau.AUDIO\_FILE\_ENCODING\_FLOAT

sunau.AUDIO\_FILE\_ENCODING\_DOUBLE

sunau.AUDIO\_FILE\_ENCODING\_ADPCM\_G721

sunau.AUDIO\_FILE\_ENCODING\_ADPCM\_G722

sunau.AUDIO\_FILE\_ENCODING\_ADPCM\_G723\_3

sunau.AUDIO\_FILE\_ENCODING\_ADPCM\_G723\_5

Additional known values of the encoding field from the AU header, but which are not supported by this module.

## AU\_read Objects

AU\_read objects, as returned by `open()` above, have the following methods:

`AU_read.close()`

Close the stream, and make the instance unusable. (This is called automatically on deletion.)

`AU_read.getnchannels()`

Returns number of audio channels (1 for mono, 2 for stereo).

`AU_read.getsampwidth()`

Returns sample width in bytes.

`AU_read.getframerate()`

Returns sampling frequency.

`AU_read.getnframes()`

Returns number of audio frames.

`AU_read.getcomptype()`

Returns compression type. Supported compression types are 'ULAW', 'ALAW' and 'NONE'.

`AU_read.getcompname()`

Human-readable version of `getcomptype()`. The supported types have the respective names 'CCITT G.711 u-law', 'CCITT G.711 A-law' and 'not compressed'.

`AU_read.getparams()`

Returns a `namedtuple()` (nchannels, sampwidth,

`framerate, nframes, comptype, compname)`, equivalent to output of the **`get*()`** methods.

**`AU_read.readframes(n)`**

Reads and returns at most *n* frames of audio, as a **`bytes`** object. The data will be returned in linear format. If the original data is in u-LAW format, it will be converted.

**`AU_read.rewind()`**

Rewind the file pointer to the beginning of the audio stream.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

**`AU_read.setpos(pos)`**

Set the file pointer to the specified position. Only values returned from **`tell()`** should be used for *pos*.

**`AU_read.tell()`**

Return current file pointer position. Note that the returned value has nothing to do with the actual position in the file.

The following two functions are defined for compatibility with the **`aifc`**, and don’t do anything interesting.

**`AU_read.getmarkers()`**

Returns `None`.

**`AU_read.getmark(id)`**

Raise an error.

## AU\_write Objects

AU\_write objects, as returned by **`open()`** above, have the following methods:

`AU_write.setnchannels(n)`

Set the number of channels.

`AU_write.setsampwidth(n)`

Set the sample width (in bytes.)

*Changed in version 3.4:* Added support for 24-bit samples.

`AU_write.setframerate(n)`

Set the frame rate.

`AU_write.setnframes(n)`

Set the number of frames. This can be later changed, when and if more frames are written.

`AU_write.setcomptype(type, name)`

Set the compression type and description. Only 'NONE' and 'ULAW' are supported on output.

`AU_write.setparams(tuple)`

The *tuple* should be (`nchannels`, `sampwidth`, `framerate`, `nframes`, `comptype`, `compname`), with values valid for the **set\*()** methods. Set all parameters.

`AU_write.tell()`

Return current position in the file, with the same disclaimer for the `AU_read.tell()` and `AU_read.setpos()` methods.

`AU_write.writeframesraw(data)`

Write audio frames, without correcting *nframes*.

*Changed in version 3.4:* Any [bytes-like object](#) is now accepted.

`AU_write.writeframes(data)`

Write audio frames and make sure *nframes* is correct.

*Changed in version 3.4:* Any [bytes-like object](#) is now accepted.

`AU_write.close()`

Make sure *nframes* is correct, and close the file.

This method is called upon deletion.

Note that it is invalid to set any parameters after calling **`writeframes()`** or **`writeframesraw()`**.

# telnetlib — Telnet client

**Source code:** [Lib/telnetlib.py](https://github.com/python/cpython/tree/3.12/Lib/telnetlib.py) [https://github.com/python/cpython/tree/3.12/Lib/telnetlib.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **telnetlib** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#telnetlib) [https://peps.python.org/pep-0594/#telnetlib] for details and alternatives).

---

The **telnetlib** module provides a **Telnet** class that implements the Telnet protocol. See [RFC 854](https://datatracker.ietf.org/doc/html/rfc854.html) [https://datatracker.ietf.org/doc/html/rfc854.html] for details about the protocol. In addition, it provides symbolic constants for the protocol characters (see below), and for the telnet options. The symbolic names of the telnet options follow the definitions in `arpa/telnet.h`, with the leading `TELOPT_` removed. For symbolic names of options which are traditionally not included in `arpa/telnet.h`, see the module source itself.

The symbolic constants for the telnet commands are: IAC, DONT, DO, WONT, WILL, SE (Subnegotiation End), NOP (No Operation), DM (Data Mark), BRK (Break), IP (Interrupt process), AO (Abort output), AYT (Are You There), EC (Erase Character), EL (Erase Line), GA (Go Ahead), SB (Subnegotiation Begin).

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emsripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

`class telnetlib.Telnet(host=None, port=0[, timeout])`

**Telnet** represents a connection to a Telnet server. The instance is initially not connected by default; the **open()** method must be used to establish a connection. Alternatively, the host name and optional port number can be passed to the constructor too, in which case the connection to the server

will be established before the constructor returns. The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not reopen an already connected instance.

This class has many `read_*()` methods. Note that some of them raise `EOFError` when the end of the connection is read, because they can return an empty string for other reasons. See the individual descriptions below.

A `Telnet` object is a context manager and can be used in a `with` statement. When the `with` block ends, the `close()` method is called:

```
>>> from telnetlib import Telnet
>>> with Telnet('localhost', 23) as tn:
...     tn.interact()
...
```

*Changed in version 3.6:* Context manager support added

## See also

**RFC 854** [<https://datatracker.ietf.org/doc/html/rfc854.html>] - **Telnet Protocol Specification**

Definition of the Telnet protocol.

# Telnet Objects

`Telnet` instances have the following methods:

`Telnet.read_until(expected, timeout=None)`

Read until a given byte string, *expected*, is encountered or until *timeout* seconds have passed.

When no match is found, return whatever is available instead, possibly empty bytes. Raise `EOFError` if the connection is

closed and no cooked data is available.

#### `Telnet.read_all()`

Read all data until EOF as bytes; block until connection closed.

#### `Telnet.read_some()`

Read at least one byte of cooked data unless EOF is hit. Return `b''` if EOF is hit. Block if no data is immediately available.

#### `Telnet.read_very_eager()`

Read everything that can be without blocking in I/O (eager).

Raise `EOFError` if connection closed and no cooked data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

#### `Telnet.read_eager()`

Read readily available data.

Raise `EOFError` if connection closed and no cooked data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

#### `Telnet.read_lazy()`

Process and return data already in the queues (lazy).

Raise `EOFError` if connection closed and no data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

#### `Telnet.read_very_lazy()`

Return any data available in the cooked queue (very lazy).

Raise `EOFError` if connection closed and no data available. Return `b''` if no cooked data available otherwise. This

method never blocks.

`Telnet.read_sb_data()`

Return the data collected between a SB/SE pair (suboption begin/end). The callback should access these data when it was invoked with a SE command. This method never blocks.

`Telnet.open(host, port=0[, timeout])`

Connect to a host. The optional second argument is the port number, which defaults to the standard Telnet port (23). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not try to reopen an already connected instance.

Raises an [auditing event](#) `telnetlib.Telnet.open` with arguments `self`, `host`, `port`.

`Telnet.msg(msg, *args)`

Print a debug message when the debug level is `> 0`. If extra arguments are present, they are substituted in the message using the standard string formatting operator.

`Telnet.set_debuglevel(debuglevel)`

Set the debug level. The higher the value of *debuglevel*, the more debug output you get (on `sys.stdout`).

`Telnet.close()`

Close the connection.

`Telnet.get_socket()`

Return the socket object used internally.

`Telnet.fileno()`

Return the file descriptor of the socket object used internally.

`Telnet.write(buffer)`

Write a byte string to the socket, doubling any IAC characters. This can block if the connection is blocked. May raise `OSError` if the connection is closed.

Raises an `auditing event` `telnetlib.Telnet.write` with arguments `self, buffer`.

*Changed in version 3.3:* This method used to raise `socket.error`, which is now an alias of `OSError`.

`Telnet.interact()`

Interaction function, emulates a very dumb Telnet client.

`Telnet.mt_interact()`

Multithreaded version of `interact()`.

`Telnet.expect(list, timeout=None)`

Read until one from a list of a regular expressions matches.

The first argument is a list of regular expressions, either compiled (`regex objects`) or uncompiled (byte strings). The optional second argument is a timeout, in seconds; the default is to block indefinitely.

Return a tuple of three items: the index in the list of the first regular expression that matches; the match object returned; and the bytes read up till and including the match.

If end of file is found and no bytes were read, raise `EOFError`. Otherwise, when nothing matches, return `(-1, None, data)` where `data` is the bytes received so far (may be empty bytes if a timeout happened).

If a regular expression ends with a greedy match (such as `. *`) or if more than one expression can match the same input, the results are non-deterministic, and may depend on the I/O timing.

Telnet.set\_option\_negotiation\_callback(*callback*)

Each time a telnet option is read on the input flow, this *callback* (if set) is called with the following parameters: `callback(telnet socket, command (DO/DONT/WILL/WONT), option)`. No other action is done afterwards by telnetlib.

## Telnet Example

A simple example illustrating typical use:

```
import getpass
import telnetlib

HOST = "localhost"
user = input("Enter your remote account: ")
password = getpass.getpass()

tn = telnetlib.Telnet(HOST)

tn.read_until(b"login: ")
tn.write(user.encode('ascii') + b"\n")
if password:
    tn.read_until(b"Password: ")
    tn.write(password.encode('ascii') + b"\n")

tn.write(b"ls\n")
tn.write(b"exit\n")

print(tn.read_all().decode('ascii'))
```

# uu — Encode and decode uuencode files

**Source code:** [Lib/uu.py](https://github.com/python/cpython/tree/3.12/Lib/uu.py) [https://github.com/python/cpython/tree/3.12/Lib/uu.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **uu** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#uu-and-the-uu-encoding) [https://peps.python.org/pep-0594/#uu-and-the-uu-encoding] for details). **base64** is a modern alternative.

---

This module encodes and decodes files in uuencode format, allowing arbitrary binary data to be transferred over ASCII-only connections. Wherever a file argument is expected, the methods accept a file-like object. For backwards compatibility, a string containing a pathname is also accepted, and the corresponding file will be opened for reading and writing; the pathname `'-'` is understood to mean the standard input or output. However, this interface is deprecated; it's better for the caller to open the file itself, and be sure that, when required, the mode is `'rb'` or `'wb'` on Windows.

This code was contributed by Lance Ellinghouse, and modified by Jack Jansen.

The **uu** module defines the following functions:

```
uu.encode(in_file, out_file, name=None, mode=None, *,  
backtick=False)
```

Uuencode file *in\_file* into file *out\_file*. The uuencoded file will have the header specifying *name* and *mode* as the defaults for the results of decoding the file. The default defaults are taken from *in\_file*, or `'-'` and `0o666` respectively. If *backtick* is true, zeros are represented by `' '` instead of spaces.

*Changed in version 3.7:* Added the *backtick* parameter.

`uu.decode(in_file, out_file=None, mode=None, quiet=False)`

This call decodes uuencoded file *in\_file* placing the result on file *out\_file*. If *out\_file* is a pathname, *mode* is used to set the permission bits if the file must be created. Defaults for *out\_file* and *mode* are taken from the uuencode header. However, if the file specified in the header already exists, a `uu.Error` is raised.

`decode()` may print a warning to standard error if the input was produced by an incorrect uuencoder and Python could recover from that error. Setting *quiet* to a true value silences this warning.

*exception* `uu.Error`

Subclass of `Exception`, this can be raised by `uu.decode()` under various situations, such as described above, but also including a badly formatted header, or truncated input file.

**See also**

**Module** `binascii`

Support module containing ASCII-to-binary and binary-to-ASCII conversions.

# **xdrlib** — Encode and decode XDR data

**Source code:** [Lib/xdrlib.py](https://github.com/python/cpython/tree/3.12/Lib/xdrlib.py) [https://github.com/python/cpython/tree/3.12/Lib/xdrlib.py]

*Deprecated since version 3.11, will be removed in version 3.13:* The **xdrlib** module is deprecated (see [PEP 594](https://peps.python.org/pep-0594/#xdrlib) [https://peps.python.org/pep-0594/#xdrlib] for details).

---

The **xdrlib** module supports the External Data Representation Standard as described in [RFC 1014](https://datatracker.ietf.org/doc/html/rfc1014.html) [https://datatracker.ietf.org/doc/html/rfc1014.html], written by Sun Microsystems, Inc. June 1987. It supports most of the data types described in the RFC.

The **xdrlib** module defines two classes, one for packing variables into XDR representation, and another for unpacking from XDR representation. There are also two exception classes.

`class xdrlib.Packer`

**Packer** is the class for packing data into XDR representation. The **Packer** class is instantiated with no arguments.

`class xdrlib.Unpacker(data)`

**Unpacker** is the complementary class which unpacks XDR data values from a string buffer. The input buffer is given as *data*.

## See also

[RFC 1014](https://datatracker.ietf.org/doc/html/rfc1014.html) [https://datatracker.ietf.org/doc/html/rfc1014.html] - **XDR: External Data Representation Standard**

This RFC defined the encoding of data which was XDR at

the time this module was originally written. It has apparently been obsoleted by [RFC 1832](https://datatracker.ietf.org/doc/html/rfc1832.html) [https://datatracker.ietf.org/doc/html/rfc1832.html].

**RFC 1832** [https://datatracker.ietf.org/doc/html/rfc1832.html] - **XDR: External Data Representation Standard**

Newer RFC that provides a revised definition of XDR.

## Packer Objects

**Packer** instances have the following methods:

`Packer.get_buffer()`

Returns the current pack buffer as a string.

`Packer.reset()`

Resets the pack buffer to the empty string.

In general, you can pack any of the most common XDR data types by calling the appropriate `pack_type()` method. Each method takes a single argument, the value to pack. The following simple data type packing methods are supported: **`pack_uint()`**, **`pack_int()`**, **`pack_enum()`**, **`pack_bool()`**, **`pack_uhyper()`**, and **`pack_hyper()`**.

`Packer.pack_float(value)`

Packs the single-precision floating point number *value*.

`Packer.pack_double(value)`

Packs the double-precision floating point number *value*.

The following methods support packing strings, bytes, and opaque data:

`Packer.pack_fstring(n, s)`

Packs a fixed length string, *s*. *n* is the length of the string but it is *not* packed into the data buffer. The string is padded with

null bytes if necessary to guaranteed 4 byte alignment.

`Packer.pack_fopaque(n, data)`

Packs a fixed length opaque data stream, similarly to `pack_fstring()`.

`Packer.pack_string(s)`

Packs a variable length string, *s*. The length of the string is first packed as an unsigned integer, then the string data is packed with `pack_fstring()`.

`Packer.pack_opaque(data)`

Packs a variable length opaque data string, similarly to `pack_string()`.

`Packer.pack_bytes(bytes)`

Packs a variable length byte stream, similarly to `pack_string()`.

The following methods support packing arrays and lists:

`Packer.pack_list(list, pack_item)`

Packs a *list* of homogeneous items. This method is useful for lists with an indeterminate size; i.e. the size is not available until the entire list has been walked. For each item in the list, an unsigned integer 1 is packed first, followed by the data value from the list. *pack\_item* is the function that is called to pack the individual item. At the end of the list, an unsigned integer 0 is packed.

For example, to pack a list of integers, the code might appear like this:

```
import xdrllib
p = xdrllib.Packer()
p.pack_list([1, 2, 3], p.pack_int)
```

`Packer.pack_farray(n, array, pack_item)`

Packs a fixed length list (*array*) of homogeneous items. *n* is the length of the list; it is *not* packed into the buffer, but a **ValueError** exception is raised if `len(array)` is not equal to *n*. As above, *pack\_item* is the function used to pack each element.

`Packer.pack_array(list, pack_item)`

Packs a variable length *list* of homogeneous items. First, the length of the list is packed as an unsigned integer, then each element is packed as in `pack_farray()` above.

## Unpacker Objects

The **Unpacker** class offers the following methods:

`Unpacker.reset(data)`

Resets the string buffer with the given *data*.

`Unpacker.get_position()`

Returns the current unpack position in the data buffer.

`Unpacker.set_position(position)`

Sets the data buffer unpack position to *position*. You should be careful about using `get_position()` and `set_position()`.

`Unpacker.get_buffer()`

Returns the current unpack data buffer as a string.

`Unpacker.done()`

Indicates unpack completion. Raises an **Error** exception if all of the data has not been unpacked.

In addition, every data type that can be packed with a **Packer**, can be unpacked with an **Unpacker**. Unpacking methods are of

the form `unpack_type()`, and take no arguments. They return the unpacked object.

`Unpacker.unpack_float()`

Unpacks a single-precision floating point number.

`Unpacker.unpack_double()`

Unpacks a double-precision floating point number, similarly to `unpack_float()`.

In addition, the following methods unpack strings, bytes, and opaque data:

`Unpacker.unpack_fstring(n)`

Unpacks and returns a fixed length string. *n* is the number of characters expected. Padding with null bytes to guaranteed 4 byte alignment is assumed.

`Unpacker.unpack_fopaque(n)`

Unpacks and returns a fixed length opaque data stream, similarly to `unpack_fstring()`.

`Unpacker.unpack_string()`

Unpacks and returns a variable length string. The length of the string is first unpacked as an unsigned integer, then the string data is unpacked with `unpack_fstring()`.

`Unpacker.unpack_opaque()`

Unpacks and returns a variable length opaque data string, similarly to `unpack_string()`.

`Unpacker.unpack_bytes()`

Unpacks and returns a variable length byte stream, similarly to `unpack_string()`.

The following methods support unpacking arrays and lists:

`Unpacker.unpack_list(unpack_item)`

Unpacks and returns a list of homogeneous items. The list is unpacked one element at a time by first unpacking an unsigned integer flag. If the flag is 1, then the item is unpacked and appended to the list. A flag of 0 indicates the end of the list. *unpack\_item* is the function that is called to unpack the items.

`Unpacker.unpack_farray(n, unpack_item)`

Unpacks and returns (as a list) a fixed length array of homogeneous items. *n* is number of list elements to expect in the buffer. As above, *unpack\_item* is the function used to unpack each element.

`Unpacker.unpack_array(unpack_item)`

Unpacks and returns a variable length *list* of homogeneous items. First, the length of the list is unpacked as an unsigned integer, then each element is unpacked as in `unpack_farray()` above.

## Exceptions

Exceptions in this module are coded as class instances:

*exception* `xdrlib.Error`

The base exception class. `Error` has a single public attribute `msg` containing the description of the error.

*exception* `xdrlib.ConversionError`

Class derived from `Error`. Contains no additional instance variables.

Here is an example of how you would catch one of these exceptions:

```
import xdrlib
p = xdrlib.Packer()
try:
```

```
    p.pack_double(8.01)
except xdrlib.ConversionError as instance:
    print('packing the double failed:', instance.msg)
```

# Security Considerations

The following modules have specific security considerations:

- **base64**: [base64 security considerations](https://datatracker.ietf.org/doc/html/rfc4648.html) in **RFC 4648** [https://datatracker.ietf.org/doc/html/rfc4648.html]
- **cgi**: [CGI security considerations](#)
- **hashlib**: all constructors take a “usedforsecurity” keyword-only argument disabling known insecure and blocked algorithms
- **http.server** is not suitable for production use, only implementing basic security checks. See the [security considerations](#).
- **logging**: Logging configuration uses eval()
- **multiprocessing**: [Connection.recv\(\)](#) uses pickle
- **pickle**: [Restricting globals in pickle](#)
- **random** shouldn't be used for security purposes, use **secrets** instead
- **shelve**: [shelve is based on pickle and thus unsuitable for dealing with untrusted sources](#)
- **ssl**: [SSL/TLS security considerations](#)
- **subprocess**: [Subprocess security considerations](#)
- **tempfile**: [mktemp is deprecated due to vulnerability to race conditions](#)
- **xml**: [XML vulnerabilities](#)
- **zipfile**: [maliciously prepared .zip files can cause disk volume exhaustion](#)

The **-I** command line option can be used to run Python in isolated mode. When it cannot be used, the **-P** option or the **PYTHONSAFEPATH** environment variable can be used to not prepend a potentially unsafe path to **sys.path** such as the current directory, the script's directory or an empty string.

# Extending and Embedding the Python Interpreter

This document describes how to write modules in C or C++ to extend the Python interpreter with new modules. Those modules can not only define new functions but also new object types and their methods. The document also describes how to embed the Python interpreter in another application, for use as an extension language. Finally, it shows how to compile and link extension modules so that they can be loaded dynamically (at run time) into the interpreter, if the underlying operating system supports this feature.

This document assumes basic knowledge about Python. For an informal introduction to the language, see [The Python Tutorial](#). [The Python Language Reference](#) gives a more formal definition of the language. [The Python Standard Library](#) documents the existing object types, functions and modules (both built-in and written in Python) that give the language its wide application range.

For a detailed description of the whole Python/C API, see the separate [Python/C API Reference Manual](#).

## Recommended third party tools

This guide only covers the basic tools for creating extensions provided as part of this version of CPython. Third party tools like [Cython](https://cython.org/) [https://cython.org/], [cffi](https://cffi.readthedocs.io) [https://cffi.readthedocs.io], [SWIG](https://www.swig.org) [https://www.swig.org] and [Numba](https://numba.pydata.org/) [https://numba.pydata.org/] offer both simpler and more sophisticated approaches to creating C and C++ extensions for Python.

**See also**

**Python Packaging User Guide: Binary Extensions** [<https://packaging.python.org/guides/packaging-binary-extensions/>]

The Python Packaging User Guide not only covers several available tools that simplify the creation of binary extensions, but also discusses the various reasons why creating an extension module may be desirable in the first place.

## Creating extensions without third party tools

This section of the guide covers creating C and C++ extensions without assistance from third party tools. It is intended primarily for creators of those tools, rather than being a recommended way to create your own C extensions.

## Embedding the CPython runtime in a larger application

Sometimes, rather than creating an extension that runs inside the Python interpreter as the main application, it is desirable to instead embed the CPython runtime inside a larger application. This section covers some of the details involved in doing that successfully.

- 1. Embedding Python in Another Application
  - 1.1. Very High Level Embedding
  - 1.2. Beyond Very High Level Embedding: An overview

# 1. Extending Python with C or C++

It is quite easy to add new built-in modules to Python, if you know how to program in C. Such *extension modules* can do two things that can't be done directly in Python: they can implement new built-in object types, and they can call C library functions and system calls.

To support extensions, the Python API (Application Programmers Interface) defines a set of functions, macros and variables that provide access to most aspects of the Python run-time system. The Python API is incorporated in a C source file by including the header `"Python.h"`.

The compilation of an extension module depends on its intended use as well as on your system setup; details are given in later chapters.

## Note

The C extension interface is specific to CPython, and extension modules do not work on other Python implementations. In many cases, it is possible to avoid writing C extensions and preserve portability to other implementations. For example, if your use case is calling C library functions or system calls, you should consider using the `ctypes` module or the `cffi` [<https://cffi.readthedocs.io/>] library rather than writing custom C code. These modules let you write Python code to interface with C code and are more portable between implementations of Python than writing and compiling a C extension module.

## 1.1. A Simple Example

Let's create an extension module called `spam` (the favorite food of

Monty Python fans...) and let's say we want to create a Python interface to the C library function `system()` [1](#). This function takes a null-terminated character string as argument and returns an integer. We want this function to be callable from Python as follows:

```
>>> import spam
>>> status = spam.system("ls -l")
```

Begin by creating a file `spammodule.c`. (Historically, if a module is called `spam`, the C file containing its implementation is called `spammodule.c`; if the module name is very long, like `spammify`, the module name can be just `spammify.c`.)

The first two lines of our file can be:

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>
```

which pulls in the Python API (you can add a comment describing the purpose of the module and a copyright notice if you like).

## Note

Since Python may define some pre-processor definitions which affect the standard headers on some systems, you *must* include `Python.h` before any standard headers are included.

It is recommended to always define `PY_SSIZE_T_CLEAN` before including `Python.h`. See [Extracting Parameters in Extension Functions](#) for a description of this macro.

All user-visible symbols defined by `Python.h` have a prefix of `Py` or `PY`, except those defined in standard header files. For convenience, and since they are used extensively by the Python interpreter, "`Python.h`" includes a few standard header files: `<stdio.h>`, `<string.h>`, `<errno.h>`, and `<stdlib.h>`. If the latter header file does not exist on your system, it declares the functions `malloc()`, `free()` and `realloc()` directly.

The next thing we add to our module file is the C function that will be called when the Python expression `spam.system(string)` is evaluated (we'll see shortly how it ends up being called):

```
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = system(command);
    return PyLong_FromLong(sts);
}
```

There is a straightforward translation from the argument list in Python (for example, the single expression `"ls -l"`) to the arguments passed to the C function. The C function always has two arguments, conventionally named *self* and *args*.

The *self* argument points to the module object for module-level functions; for a method it would point to the object instance.

The *args* argument will be a pointer to a Python tuple object containing the arguments. Each item of the tuple corresponds to an argument in the call's argument list. The arguments are Python objects — in order to do anything with them in our C function we have to convert them to C values. The function

**`PyArg_ParseTuple()`** in the Python API checks the argument types and converts them to C values. It uses a template string to determine the required types of the arguments as well as the types of the C variables into which to store the converted values. More about this later.

**`PyArg_ParseTuple()`** returns true (nonzero) if all arguments have the right type and its components have been stored in the variables whose addresses are passed. It returns false (zero) if an invalid argument list was passed. In the latter case it also raises an appropriate exception so the calling function can return `NULL`

immediately (as we saw in the example).

## 1.2. Intermezzo: Errors and Exceptions

An important convention throughout the Python interpreter is the following: when a function fails, it should set an exception condition and return an error value (usually `-1` or a `NULL` pointer). Exception information is stored in three members of the interpreter's thread state. These are `NULL` if there is no exception. Otherwise they are the C equivalents of the members of the Python tuple returned by `sys.exc_info()`. These are the exception type, exception instance, and a traceback object. It is important to know about them to understand how errors are passed around.

The Python API defines a number of functions to set various types of exceptions.

The most common one is `PyErr_SetString()`. Its arguments are an exception object and a C string. The exception object is usually a predefined object like `PyExc_ZeroDivisionError`. The C string indicates the cause of the error and is converted to a Python string object and stored as the “associated value” of the exception.

Another useful function is `PyErr_SetFromErrno()`, which only takes an exception argument and constructs the associated value by inspection of the global variable `errno`. The most general function is `PyErr_SetObject()`, which takes two object arguments, the exception and its associated value. You don't need to `Py_INCREF()` the objects passed to any of these functions.

You can test non-destructively whether an exception has been set with `PyErr_Occurred()`. This returns the current exception object, or `NULL` if no exception has occurred. You normally don't need to call `PyErr_Occurred()` to see whether an error occurred in a function call, since you should be able to tell from the return value.

When a function *f* that calls another function *g* detects that the latter fails, *f* should itself return an error value (usually `NULL` or `-1`). It should *not* call one of the `PyErr_*` functions — one has

already been called by *g*. *f*'s caller is then supposed to also return an error indication to *its* caller, again *without* calling `PyErr_*`, and so on — the most detailed cause of the error was already reported by the function that first detected it. Once the error reaches the Python interpreter's main loop, this aborts the currently executing Python code and tries to find an exception handler specified by the Python programmer.

(There are situations where a module can actually give a more detailed error message by calling another `PyErr_*` function, and in such cases it is fine to do so. As a general rule, however, this is not necessary, and can cause information about the cause of the error to be lost: most operations can fail for a variety of reasons.)

To ignore an exception set by a function call that failed, the exception condition must be cleared explicitly by calling `PyErr_Clear()`. The only time C code should call `PyErr_Clear()` is if it doesn't want to pass the error on to the interpreter but wants to handle it completely by itself (possibly by trying something else, or pretending nothing went wrong).

Every failing `malloc()` call must be turned into an exception — the direct caller of `malloc()` (or `realloc()`) must call `PyErr_NoMemory()` and return a failure indicator itself. All the object-creating functions (for example, `PyLong_FromLong()`) already do this, so this note is only relevant to those who call `malloc()` directly.

Also note that, with the important exception of `PyArg_ParseTuple()` and friends, functions that return an integer status usually return a positive value or zero for success and `-1` for failure, like Unix system calls.

Finally, be careful to clean up garbage (by making `Py_XDECREF()` or `Py_DECREF()` calls for objects you have already created) when you return an error indicator!

The choice of which exception to raise is entirely yours. There are predeclared C objects corresponding to all built-in Python exceptions, such as `PyExc_ZeroDivisionError`, which you can use directly. Of course, you should choose exceptions wisely —

don't use **PyExc\_TypeError** to mean that a file couldn't be opened (that should probably be **PyExc\_OSError**). If something's wrong with the argument list, the **PyArg\_ParseTuple()** function usually raises **PyExc\_TypeError**. If you have an argument whose value must be in a particular range or must satisfy other conditions, **PyExc\_ValueError** is appropriate.

You can also define a new exception that is unique to your module. For this, you usually declare a static object variable at the beginning of your file:

```
static PyObject *SpamError;
```

and initialize it in your module's initialization function (**PyInit\_spam()**) with an exception object:

```
PyMODINIT_FUNC
PyInit_spam(void)
{
    PyObject *m;

    m = PyModule_Create(&spammodule);
    if (m == NULL)
        return NULL;

    SpamError = PyErr_NewException("spam.error", NULL, NULL);
    Py_XINCREF(SpamError);
    if (PyModule_AddObject(m, "error", SpamError) < 0) {
        Py_XDECREF(SpamError);
        Py_CLEAR(SpamError);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

Note that the Python name for the exception object is **spam.error**. The **PyErr\_NewException()** function may create a class with the base class being **Exception** (unless another class

is passed in instead of `NULL`), described in [Built-in Exceptions](#).

Note also that the `SpamError` variable retains a reference to the newly created exception class; this is intentional! Since the exception could be removed from the module by external code, an owned reference to the class is needed to ensure that it will not be discarded, causing `SpamError` to become a dangling pointer. Should it become a dangling pointer, C code which raises the exception could cause a core dump or other unintended side effects.

We discuss the use of `PyMODINIT_FUNC` as a function return type later in this sample.

The `spam.error` exception can be raised in your extension module using a call to `PyErr_SetString()` as shown below:

```
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = system(command);
    if (sts < 0) {
        PyErr_SetString(SpamError, "System command failed");
        return NULL;
    }
    return PyLong_FromLong(sts);
}
```

## 1.3. Back to the Example

Going back to our example function, you should now be able to understand this statement:

```
if (!PyArg_ParseTuple(args, "s", &command))
    return NULL;
```

It returns `NULL` (the error indicator for functions returning object pointers) if an error is detected in the argument list, relying on the exception set by `PyArg_ParseTuple()`. Otherwise the string value of the argument has been copied to the local variable `command`. This is a pointer assignment and you are not supposed to modify the string to which it points (so in Standard C, the variable `command` should properly be declared as `const char *command`).

The next statement is a call to the Unix function `system()`, passing it the string we just got from `PyArg_ParseTuple()`:

```
sts = system(command);
```

Our `spam.system()` function must return the value of `sts` as a Python object. This is done using the function `PyLong_FromLong()`.

```
return PyLong_FromLong(sts);
```

In this case, it will return an integer object. (Yes, even integers are objects on the heap in Python!)

If you have a C function that returns no useful argument (a function returning void), the corresponding Python function must return `None`. You need this idiom to do so (which is implemented by the `Py_RETURN_NONE` macro):

```
Py_INCREF(Py_None);  
return Py_None;
```

`Py_None` is the C name for the special Python object `None`. It is a genuine Python object rather than a `NULL` pointer, which means “error” in most contexts, as we have seen.

## 1.4. The Module’s Method Table and Initialization Function

I promised to show how `spam.system()` is called from Python programs. First, we need to list its name and address in a “method

table”:

```
static PyMethodDef SpamMethods[] = {
    ...
    {"system", spam_system, METH_VARARGS,
     "Execute a shell command."},
    ...
    {NULL, NULL, 0, NULL}           /* Sentinel */
};
```

Note the third entry (`METH_VARARGS`). This is a flag telling the interpreter the calling convention to be used for the C function. It should normally always be `METH_VARARGS` or `METH_VARARGS | METH_KEYWORDS`; a value of `0` means that an obsolete variant of `PyArg_ParseTuple()` is used.

When using only `METH_VARARGS`, the function should expect the Python-level parameters to be passed in as a tuple acceptable for parsing via `PyArg_ParseTuple()`; more information on this function is provided below.

The `METH_KEYWORDS` bit may be set in the third field if keyword arguments should be passed to the function. In this case, the C function should accept a third `PyObject *` parameter which will be a dictionary of keywords. Use `PyArg_ParseTupleAndKeywords()` to parse the arguments to such a function.

The method table must be referenced in the module definition structure:

```
static struct PyModuleDef spammodule = {
    PyModuleDef_HEAD_INIT,
    "spam", /* name of module */
    spam_doc, /* module documentation, may be NULL */
    -1, /* size of per-interpreter state of the module
         or -1 if the module keeps state in global namespace */
    SpamMethods
};
```

This structure, in turn, must be passed to the interpreter in the module's initialization function. The initialization function must be named **PyInit\_name()**, where *name* is the name of the module, and should be the only non-static item defined in the module file:

```
PyMODINIT_FUNC
PyInit_spam(void)
{
    return PyModule_Create(&spammodule);
}
```

Note that **PyMODINIT\_FUNC** declares the function as PyObject \* return type, declares any special linkage declarations required by the platform, and for C++ declares the function as extern "C".

When the Python program imports module **spam** for the first time, **PyInit\_spam()** is called. (See below for comments about embedding Python.) It calls **PyModule\_Create()**, which returns a module object, and inserts built-in function objects into the newly created module based upon the table (an array of **PyMethodDef** structures) found in the module definition. **PyModule\_Create()** returns a pointer to the module object that it creates. It may abort with a fatal error for certain errors, or return NULL if the module could not be initialized satisfactorily. The init function must return the module object to its caller, so that it then gets inserted into `sys.modules`.

When embedding Python, the **PyInit\_spam()** function is not called automatically unless there's an entry in the **PyImport\_Inittab** table. To add the module to the initialization table, use **PyImport\_AppendInittab()**, optionally followed by an import of the module:

```
int
main(int argc, char *argv[])
{
    wchar_t *program = Py_DecodeLocale(argv[0], NULL);
    if (program == NULL) {
        fprintf(stderr, "Fatal error: cannot decode argv[0]\n");
        exit(1);
    }
    Py_Initialize();
    PyImport_AppendInittab("spam", PyInit_spam);
    Py_Import("spam");
    PyRun_SimpleString("import spam\n");
    Py_Finalize();
    free(program);
    return 0;
}
```

```

        exit(1);
    }

    /* Add a built-in module, before Py_Initialize */
    if (PyImport_AppendInittab("spam", PyInit_spam) == -1)
        fprintf(stderr, "Error: could not extend in-built\n");
    exit(1);
}

/* Pass argv[0] to the Python interpreter */
Py_SetProgramName(program);

/* Initialize the Python interpreter.  Required.
   If this step fails, it will be a fatal error. */
Py_Initialize();

/* Optionally import the module; alternatively,
   import can be deferred until the embedded script
   imports it. */
PyObject *pmodule = PyImport_ImportModule("spam");
if (!pmodule) {
    PyErr_Print();
    fprintf(stderr, "Error: could not import module\n");
}

...

PyMem_RawFree(program);
return 0;
}

```

## Note

Removing entries from `sys.modules` or importing compiled modules into multiple interpreters within a process (or following a **fork()** without an intervening **exec()**) can create problems for some extension modules. Extension module authors should exercise caution when initializing internal data structures.

A more substantial example module is included in the Python source distribution as `Modules/xxmodule.c`. This file may be used as a template or simply read as an example.

## Note

Unlike our `spam` example, `xxmodule` uses *multi-phase initialization* (new in Python 3.5), where a `PyModuleDef` structure is returned from `PyInit_spam`, and creation of the module is left to the import machinery. For details on multi-phase initialization, see [PEP 489](https://peps.python.org/pep-0489/) [https://peps.python.org/pep-0489/].

## 1.5. Compilation and Linkage

There are two more things to do before you can use your new extension: compiling and linking it with the Python system. If you use dynamic loading, the details may depend on the style of dynamic loading your system uses; see the chapters about building extension modules (chapter [Building C and C++ Extensions](#)) and additional information that pertains only to building on Windows (chapter [Building C and C++ Extensions on Windows](#)) for more information about this.

If you can't use dynamic loading, or if you want to make your module a permanent part of the Python interpreter, you will have to change the configuration setup and rebuild the interpreter. Luckily, this is very simple on Unix: just place your file (`spammodule.c` for example) in the `Modules/` directory of an unpacked source distribution, add a line to the file `Modules/Setup.local` describing your file:

```
spam spammodule.o
```

and rebuild the interpreter by running **make** in the toplevel directory. You can also run **make** in the `Modules/` subdirectory, but then you must first rebuild `Makefile` there by running '**make** `Makefile`'. (This is necessary each time you change the `Setup` file.)

If your module requires additional libraries to link with, these can

be listed on the line in the configuration file as well, for instance:

```
spam spammodule.o -lX11
```

## 1.6. Calling Python Functions from C

So far we have concentrated on making C functions callable from Python. The reverse is also useful: calling Python functions from C. This is especially the case for libraries that support so-called “callback” functions. If a C interface makes use of callbacks, the equivalent Python often needs to provide a callback mechanism to the Python programmer; the implementation will require calling the Python callback functions from a C callback. Other uses are also imaginable.

Fortunately, the Python interpreter is easily called recursively, and there is a standard interface to call a Python function. (I won’t dwell on how to call the Python parser with a particular string as input — if you’re interested, have a look at the implementation of the `-c` command line option in `Modules/main.c` from the Python source code.)

Calling a Python function is easy. First, the Python program must somehow pass you the Python function object. You should provide a function (or some other interface) to do this. When this function is called, save a pointer to the Python function object (be careful to `Py_INCREF()` it!) in a global variable — or wherever you see fit. For example, the following function might be part of a module definition:

```
static PyObject *my_callback = NULL;

static PyObject *
my_set_callback(PyObject *dummy, PyObject *args)
{
    PyObject *result = NULL;
    PyObject *temp;

    if (PyArg_ParseTuple(args, "O:set_callback", &temp))
        if (!PyCallable_Check(temp)) {
```

```

        PyErr_SetString(PyExc_TypeError, "parameter
        return NULL;
    }
    Py_XINCREF(temp);           /* Add a reference to
    Py_XDECREF(my_callback);    /* Dispose of previous
    my_callback = temp;         /* Remember new callba
    /* Boilerplate to return "None" */
    Py_INCREF(Py_None);
    result = Py_None;
}
return result;
}

```

This function must be registered with the interpreter using the **METH\_VARARGS** flag; this is described in section [The Module's Method Table and Initialization Function](#). The **PyArg\_ParseTuple()** function and its arguments are documented in section [Extracting Parameters in Extension Functions](#).

The macros **Py\_XINCREF()** and **Py\_XDECREF()** increment/decrement the reference count of an object and are safe in the presence of `NULL` pointers (but note that *temp* will not be `NULL` in this context). More info on them in section [Reference Counts](#).

Later, when it is time to call the function, you call the C function **PyObject\_CallObject()**. This function has two arguments, both pointers to arbitrary Python objects: the Python function, and the argument list. The argument list must always be a tuple object, whose length is the number of arguments. To call the Python function with no arguments, pass in `NULL`, or an empty tuple; to call it with one argument, pass a singleton tuple.

**Py\_BuildValue()** returns a tuple when its format string consists of zero or more format codes between parentheses. For example:

```

int arg;
PyObject *arglist;
PyObject *result;
...
arg = 123;

```

```
...
/* Time to call the callback */
arglist = Py_BuildValue("(i)", arg);
result = PyObject_CallObject(my_callback, arglist);
Py_DECREF(arglist);
```

**PyObject\_CallObject()** returns a Python object pointer: this is the return value of the Python function.

**PyObject\_CallObject()** is “reference-count-neutral” with respect to its arguments. In the example a new tuple was created to serve as the argument list, which is **Py\_DECREF()**-ed immediately after the **PyObject\_CallObject()** call.

The return value of **PyObject\_CallObject()** is “new”: either it is a brand new object, or it is an existing object whose reference count has been incremented. So, unless you want to save it in a global variable, you should somehow **Py\_DECREF()** the result, even (especially!) if you are not interested in its value.

Before you do this, however, it is important to check that the return value isn’t `NULL`. If it is, the Python function terminated by raising an exception. If the C code that called **PyObject\_CallObject()** is called from Python, it should now return an error indication to its Python caller, so the interpreter can print a stack trace, or the calling Python code can handle the exception. If this is not possible or desirable, the exception should be cleared by calling **PyErr\_Clear()**. For example:

```
if (result == NULL)
    return NULL; /* Pass error back */
...use result...
Py_DECREF(result);
```

Depending on the desired interface to the Python callback function, you may also have to provide an argument list to **PyObject\_CallObject()**. In some cases the argument list is also provided by the Python program, through the same interface that specified the callback function. It can then be saved and used in the same manner as the function object. In other cases, you may have to construct a new tuple to pass as the argument list. The simplest

way to do this is to call `Py_BuildValue()`. For example, if you want to pass an integral event code, you might use the following code:

```
PyObject *arglist;
...
arglist = Py_BuildValue("(l)", eventcode);
result = PyObject_CallObject(my_callback, arglist);
Py_DECREF(arglist);
if (result == NULL)
    return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```

Note the placement of `Py_DECREF(arglist)` immediately after the call, before the error check! Also note that strictly speaking this code is not complete: `Py_BuildValue()` may run out of memory, and this should be checked.

You may also call a function with keyword arguments by using `PyObject_Call()`, which supports arguments and keyword arguments. As in the above example, we use `Py_BuildValue()` to construct the dictionary.

```
PyObject *dict;
...
dict = Py_BuildValue("{s:i}", "name", val);
result = PyObject_Call(my_callback, NULL, dict);
Py_DECREF(dict);
if (result == NULL)
    return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```

## 1.7. Extracting Parameters in Extension Functions

The `PyArg_ParseTuple()` function is declared as follows:

```
int PyArg_ParseTuple(PyObject *arg, const char *format,
```

The *arg* argument must be a tuple object containing an argument list passed from Python to a C function. The *format* argument must be a format string, whose syntax is explained in [Parsing arguments and building values](#) in the Python/C API Reference Manual. The remaining arguments must be addresses of variables whose type is determined by the format string.

Note that while `PyArg_ParseTuple()` checks that the Python arguments have the required types, it cannot check the validity of the addresses of C variables passed to the call: if you make mistakes there, your code will probably crash or at least overwrite random bits in memory. So be careful!

Note that any Python object references which are provided to the caller are *borrowed* references; do not decrement their reference count!

Some example calls:

```
#define PY_SSIZE_T_CLEAN /* Make "s#" use Py_ssize_t rather than int */
#include <Python.h>

int ok;
int i, j;
long k, l;
const char *s;
Py_ssize_t size;

ok = PyArg_ParseTuple(args, ""); /* No arguments */
/* Python call: f() */

ok = PyArg_ParseTuple(args, "s", &s); /* A string */
/* Possible Python call: f('whoops!') */

ok = PyArg_ParseTuple(args, "lls", &k, &l, &s); /* Two ints and a string */
/* Possible Python call: f(1, 2, 'three') */

ok = PyArg_ParseTuple(args, "(ii)s#", &i, &j, &s, &size); /* A pair of ints and a string, whose size is also passed */
```

The *arg* and *format* parameters are identical to those of the `PyArg_ParseTuple()` function. The *kwdict* parameter is the dictionary of keywords received as the third parameter from the Python runtime. The *kwlist* parameter is a NULL-terminated list of strings which identify the parameters; the names are matched with the type information from *format* from left to right. On success, `PyArg_ParseTupleAndKeywords()` returns true, otherwise it returns false and raises an appropriate exception.

## Note

Nested tuples cannot be parsed when using keyword arguments! Keyword parameters passed in which are not present in the *kwlist* will cause `TypeError` to be raised.

Here is an example module which uses keywords, based on an example by Geoff Philbrick ([philbrick@hks.com](mailto:philbrick@hks.com)):

```
#define PY_SSIZE_T_CLEAN /* Make "s#" use Py_ssize_t rather than int */
#include <Python.h>

static PyObject *
keywdarg_parrot(PyObject *self, PyObject *args, PyObject *kwlist)
{
    int voltage;
    const char *state = "a stiff";
    const char *action = "voom";
    const char *type = "Norwegian Blue";

    static char *kwlist[] = {"voltage", "state", "action", "type", NULL};

    if (!PyArg_ParseTupleAndKeywords(args, kwlist, "i|ss",
                                      &voltage, &state, &action, &type))
        return NULL;

    printf("-- This parrot wouldn't %s if you put %i Volts\n", action, voltage);
    printf("-- Lovely plumage, the %s -- It's %s!\n", type, state);
}
```

```

        Py_RETURN_NONE;
    }

static PyMethodDef keywarg_methods[] = {
    /* The cast of the function is necessary since PyCFu
    * only take two PyObject* parameters, and keywarg_
    * three.
    */
    {"parrot", (PyCFunction) (void(*) (void))keywarg_parr
    "Print a lovely skit to standard output."},
    {NULL, NULL, 0, NULL} /* sentinel */
};

static struct PyModuleDef keywargmodule = {
    PyModuleDef_HEAD_INIT,
    "keywarg",
    NULL,
    -1,
    keywarg_methods
};

PyMODINIT_FUNC
PyInit_keywarg(void)
{
    return PyModule_Create(&keywargmodule);
}

```

## 1.9. Building Arbitrary Values

This function is the counterpart to [PyArg\\_ParseTuple\(\)](#). It is declared as follows:

```
PyObject *Py_BuildValue(const char *format, ...);
```

It recognizes a set of format units similar to the ones recognized by [PyArg\\_ParseTuple\(\)](#), but the arguments (which are input to the function, not output) must not be pointers, just values. It returns a new Python object, suitable for returning from a C function called from Python.

One difference with `PyArg_ParseTuple()`: while the latter requires its first argument to be a tuple (since Python argument lists are always represented as tuples internally), `Py_BuildValue()` does not always build a tuple. It builds a tuple only if its format string contains two or more format units. If the format string is empty, it returns `None`; if it contains exactly one format unit, it returns whatever object is described by that format unit. To force it to return a tuple of size 0 or one, parenthesize the format string.

Examples (to the left the call, to the right the resulting Python value):

<code>Py_BuildValue("")</code>	<code>None</code>
<code>Py_BuildValue("i", 123)</code>	<code>123</code>
<code>Py_BuildValue("iii", 123, 456, 789)</code>	<code>(123, 456, 789)</code>
<code>Py_BuildValue("s", "hello")</code>	<code>'hello'</code>
<code>Py_BuildValue("y", "hello")</code>	<code>b'hello'</code>
<code>Py_BuildValue("ss", "hello", "world")</code>	<code>('hello', 'world')</code>
<code>Py_BuildValue("s#", "hello", 4)</code>	<code>'hell'</code>
<code>Py_BuildValue("y#", "hello", 4)</code>	<code>b'hell'</code>
<code>Py_BuildValue("()")</code>	<code>()</code>
<code>Py_BuildValue("(i)", 123)</code>	<code>(123,)</code>
<code>Py_BuildValue("(ii)", 123, 456)</code>	<code>(123, 456)</code>
<code>Py_BuildValue("(i,i)", 123, 456)</code>	<code>(123, 456)</code>
<code>Py_BuildValue("[i,i]", 123, 456)</code>	<code>[123, 456]</code>
<code>Py_BuildValue("{s:i,s:i}",                                 "abc", 123, "def", 456)</code>	<code>{'abc': 123, 'def': 456}</code>
<code>Py_BuildValue("((ii)(ii)) (ii)",                                 1, 2, 3, 4, 5, 6)</code>	<code>((1, 2), (3, 4), (1, 2, 3, 4, 5, 6))</code>

## 1.10. Reference Counts

In languages like C or C++, the programmer is responsible for dynamic allocation and deallocation of memory on the heap. In C, this is done using the functions `malloc()` and `free()`. In C++, the operators `new` and `delete` are used with essentially the same meaning and we'll restrict the following discussion to the C case.

Every block of memory allocated with `malloc()` should

eventually be returned to the pool of available memory by exactly one call to **free()**. It is important to call **free()** at the right time. If a block's address is forgotten but **free()** is not called for it, the memory it occupies cannot be reused until the program terminates. This is called a *memory leak*. On the other hand, if a program calls **free()** for a block and then continues to use the block, it creates a conflict with re-use of the block through another **malloc()** call. This is called *using freed memory*. It has the same bad consequences as referencing uninitialized data — core dumps, wrong results, mysterious crashes.

Common causes of memory leaks are unusual paths through the code. For instance, a function may allocate a block of memory, do some calculation, and then free the block again. Now a change in the requirements for the function may add a test to the calculation that detects an error condition and can return prematurely from the function. It's easy to forget to free the allocated memory block when taking this premature exit, especially when it is added later to the code. Such leaks, once introduced, often go undetected for a long time: the error exit is taken only in a small fraction of all calls, and most modern machines have plenty of virtual memory, so the leak only becomes apparent in a long-running process that uses the leaking function frequently. Therefore, it's important to prevent leaks from happening by having a coding convention or strategy that minimizes this kind of errors.

Since Python makes heavy use of **malloc()** and **free()**, it needs a strategy to avoid memory leaks as well as the use of freed memory. The chosen method is called *reference counting*. The principle is simple: every object contains a counter, which is incremented when a reference to the object is stored somewhere, and which is decremented when a reference to it is deleted. When the counter reaches zero, the last reference to the object has been deleted and the object is freed.

An alternative strategy is called *automatic garbage collection*. (Sometimes, reference counting is also referred to as a garbage collection strategy, hence my use of “automatic” to distinguish the two.) The big advantage of automatic garbage collection is that the user doesn't need to call **free()** explicitly. (Another claimed

advantage is an improvement in speed or memory usage — this is no hard fact however.) The disadvantage is that for C, there is no truly portable automatic garbage collector, while reference counting can be implemented portably (as long as the functions `malloc()` and `free()` are available — which the C Standard guarantees). Maybe some day a sufficiently portable automatic garbage collector will be available for C. Until then, we'll have to live with reference counts.

While Python uses the traditional reference counting implementation, it also offers a cycle detector that works to detect reference cycles. This allows applications to not worry about creating direct or indirect circular references; these are the weakness of garbage collection implemented using only reference counting. Reference cycles consist of objects which contain (possibly indirect) references to themselves, so that each object in the cycle has a reference count which is non-zero. Typical reference counting implementations are not able to reclaim the memory belonging to any objects in a reference cycle, or referenced from the objects in the cycle, even though there are no further references to the cycle itself.

The cycle detector is able to detect garbage cycles and can reclaim them. The `gc` module exposes a way to run the detector (the `collect()` function), as well as configuration interfaces and the ability to disable the detector at runtime.

### 1.10.1. Reference Counting in Python

There are two macros, `Py_INCREF(x)` and `Py_DECREF(x)`, which handle the incrementing and decrementing of the reference count. `Py_DECREF()` also frees the object when the count reaches zero. For flexibility, it doesn't call `free()` directly — rather, it makes a call through a function pointer in the object's *type object*. For this purpose (and others), every object also contains a pointer to its type object.

The big question now remains: when to use `Py_INCREF(x)` and `Py_DECREF(x)`? Let's first introduce some terms. Nobody “owns” an object; however, you can *own a reference* to an object. An object's

reference count is now defined as the number of owned references to it. The owner of a reference is responsible for calling `Py_DECREF()` when the reference is no longer needed. Ownership of a reference can be transferred. There are three ways to dispose of an owned reference: pass it on, store it, or call `Py_DECREF()`. Forgetting to dispose of an owned reference creates a memory leak.

It is also possible to *borrow* a reference to an object. The borrower of a reference should not call `Py_DECREF()`. The borrower must not hold on to the object longer than the owner from which it was borrowed. Using a borrowed reference after the owner has disposed of it risks using freed memory and should be avoided completely.

The advantage of borrowing over owning a reference is that you don't need to take care of disposing of the reference on all possible paths through the code — in other words, with a borrowed reference you don't run the risk of leaking when a premature exit is taken. The disadvantage of borrowing over owning is that there are some subtle situations where in seemingly correct code a borrowed reference can be used after the owner from which it was borrowed has in fact disposed of it.

A borrowed reference can be changed into an owned reference by calling `Py_INCREF()`. This does not affect the status of the owner from which the reference was borrowed — it creates a new owned reference, and gives full owner responsibilities (the new owner must dispose of the reference properly, as well as the previous owner).

### 1.10.2. Ownership Rules

Whenever an object reference is passed into or out of a function, it is part of the function's interface specification whether ownership is transferred with the reference or not.

Most functions that return a reference to an object pass on ownership with the reference. In particular, all functions whose function it is to create a new object, such as `PyLong_FromLong()` and `Py_BuildValue()`, pass ownership to the receiver. Even if the object is not actually new, you still receive ownership of a new reference to that object. For instance, `PyLong_FromLong()` maintains a cache of popular values and can return a reference to a

cached item.

Many functions that extract objects from other objects also transfer ownership with the reference, for instance

`PyObject_GetAttrString()`. The picture is less clear, here, however, since a few common routines are exceptions:

`PyTuple_GetItem()`, `PyList_GetItem()`, `PyDict_GetItem()`, and `PyDict_GetItemString()` all return references that you borrow from the tuple, list or dictionary.

The function `PyImport_AddModule()` also returns a borrowed reference, even though it may actually create the object it returns: this is possible because an owned reference to the object is stored in `sys.modules`.

When you pass an object reference into another function, in general, the function borrows the reference from you — if it needs to store it, it will use `Py_INCREF()` to become an independent owner. There are exactly two important exceptions to this rule: `PyTuple_SetItem()` and `PyList_SetItem()`. These functions take over ownership of the item passed to them — even if they fail! (Note that `PyDict_SetItem()` and friends don't take over ownership — they are “normal.”)

When a C function is called from Python, it borrows references to its arguments from the caller. The caller owns a reference to the object, so the borrowed reference's lifetime is guaranteed until the function returns. Only when such a borrowed reference must be stored or passed on, it must be turned into an owned reference by calling `Py_INCREF()`.

The object reference returned from a C function that is called from Python must be an owned reference — ownership is transferred from the function to its caller.

### 1.10.3. Thin Ice

There are a few situations where seemingly harmless use of a borrowed reference can lead to problems. These all have to do with implicit invocations of the interpreter, which can cause the owner of a reference to dispose of it.

The first and most important case to know about is using `Py_DECREF()` on an unrelated object while borrowing a reference to a list item. For instance:

```
void
bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);

    PyList_SetItem(list, 1, PyLong_FromLong(0L));
    PyObject_Print(item, stdout, 0); /* BUG! */
}
```

This function first borrows a reference to `list[0]`, then replaces `list[1]` with the value `0`, and finally prints the borrowed reference. Looks harmless, right? But it's not!

Let's follow the control flow into `PyList_SetItem()`. The list owns references to all its items, so when item 1 is replaced, it has to dispose of the original item 1. Now let's suppose the original item 1 was an instance of a user-defined class, and let's further suppose that the class defined a `__del__()` method. If this class instance has a reference count of 1, disposing of it will call its `__del__()` method.

Since it is written in Python, the `__del__()` method can execute arbitrary Python code. Could it perhaps do something to invalidate the reference to `item` in `bug()`? You bet! Assuming that the list passed into `bug()` is accessible to the `__del__()` method, it could execute a statement to the effect of `del list[0]`, and assuming this was the last reference to that object, it would free the memory associated with it, thereby invalidating `item`.

The solution, once you know the source of the problem, is easy: temporarily increment the reference count. The correct version of the function reads:

```
void
no_bug(PyObject *list)
{
```

```

PyObject *item = PyList_GetItem(list, 0);

Py_INCREF(item);
PyList_SetItem(list, 1, PyLong_FromLong(0L));
PyObject_Print(item, stdout, 0);
Py_DECREF(item);
}

```

This is a true story. An older version of Python contained variants of this bug and someone spent a considerable amount of time in a C debugger to figure out why his `__del__()` methods would fail...

The second case of problems with a borrowed reference is a variant involving threads. Normally, multiple threads in the Python interpreter can't get in each other's way, because there is a global lock protecting Python's entire object space. However, it is possible to temporarily release this lock using the macro `Py_BEGIN_ALLOW_THREADS`, and to re-acquire it using `Py_END_ALLOW_THREADS`. This is common around blocking I/O calls, to let other threads use the processor while waiting for the I/O to complete. Obviously, the following function has the same problem as the previous one:

```

void
bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);
    Py_BEGIN_ALLOW_THREADS
    ...some blocking I/O call...
    Py_END_ALLOW_THREADS
    PyObject_Print(item, stdout, 0); /* BUG! */
}

```

### 1.10.4. NULL Pointers

In general, functions that take object references as arguments do not expect you to pass them `NULL` pointers, and will dump core (or cause later core dumps) if you do so. Functions that return object references generally return `NULL` only to indicate that an exception occurred. The reason for not testing for `NULL` arguments is that

functions often pass the objects they receive on to other function — if each function were to test for `NULL`, there would be a lot of redundant tests and the code would run more slowly.

It is better to test for `NULL` only at the “source:” when a pointer that may be `NULL` is received, for example, from `malloc()` or from a function that may raise an exception.

The macros `Py_INCREF()` and `Py_DECREF()` do not check for `NULL` pointers — however, their variants `Py_XINCREF()` and `Py_XDECREF()` do.

The macros for checking for a particular object type (`Pytype_Check()`) don’t check for `NULL` pointers — again, there is much code that calls several of these in a row to test an object against various different expected types, and this would generate redundant tests. There are no variants with `NULL` checking.

The C function calling mechanism guarantees that the argument list passed to C functions (`args` in the examples) is never `NULL` — in fact it guarantees that it is always a tuple [4](#).

It is a severe error to ever let a `NULL` pointer “escape” to the Python user.

## 1.11. Writing Extensions in C++

It is possible to write extension modules in C++. Some restrictions apply. If the main program (the Python interpreter) is compiled and linked by the C compiler, global or static objects with constructors cannot be used. This is not a problem if the main program is linked by the C++ compiler. Functions that will be called by the Python interpreter (in particular, module initialization functions) have to be declared using `extern "C"`. It is unnecessary to enclose the Python header files in `extern "C" {...}` — they use this form already if the symbol `__cplusplus` is defined (all recent C++ compilers define this symbol).

## 1.12. Providing a C API for an Extension

# Module

Many extension modules just provide new functions and types to be used from Python, but sometimes the code in an extension module can be useful for other extension modules. For example, an extension module could implement a type “collection” which works like lists without order. Just like the standard Python list type has a C API which permits extension modules to create and manipulate lists, this new collection type should have a set of C functions for direct manipulation from other extension modules.

At first sight this seems easy: just write the functions (without declaring them `static`, of course), provide an appropriate header file, and document the C API. And in fact this would work if all extension modules were always linked statically with the Python interpreter. When modules are used as shared libraries, however, the symbols defined in one module may not be visible to another module. The details of visibility depend on the operating system; some systems use one global namespace for the Python interpreter and all extension modules (Windows, for example), whereas others require an explicit list of imported symbols at module link time (AIX is one example), or offer a choice of different strategies (most Unices). And even if symbols are globally visible, the module whose functions one wishes to call might not have been loaded yet!

Portability therefore requires not to make any assumptions about symbol visibility. This means that all symbols in extension modules should be declared `static`, except for the module’s initialization function, in order to avoid name clashes with other extension modules (as discussed in section [The Module’s Method Table and Initialization Function](#)). And it means that symbols that *should* be accessible from other extension modules must be exported in a different way.

Python provides a special mechanism to pass C-level information (pointers) from one extension module to another one: Capsules. A Capsule is a Python data type which stores a pointer (void\*). Capsules can only be created and accessed via their C API, but they can be passed around like any other Python object. In particular, they can be assigned to a name in an extension module’s

namespace. Other extension modules can then import this module, retrieve the value of this name, and then retrieve the pointer from the Capsule.

There are many ways in which Capsules can be used to export the C API of an extension module. Each function could get its own Capsule, or all C API pointers could be stored in an array whose address is published in a Capsule. And the various tasks of storing and retrieving the pointers can be distributed in different ways between the module providing the code and the client modules.

Whichever method you choose, it's important to name your Capsules properly. The function `PyCapsule_New()` takes a name parameter (const char\*); you're permitted to pass in a `NULL` name, but we strongly encourage you to specify a name. Properly named Capsules provide a degree of runtime type-safety; there is no feasible way to tell one unnamed Capsule from another.

In particular, Capsules used to expose C APIs should be given a name following this convention:

```
modulename.attributename
```

The convenience function `PyCapsule_Import()` makes it easy to load a C API provided via a Capsule, but only if the Capsule's name matches this convention. This behavior gives C API users a high degree of certainty that the Capsule they load contains the correct C API.

The following example demonstrates an approach that puts most of the burden on the writer of the exporting module, which is appropriate for commonly used library modules. It stores all C API pointers (just one in the example!) in an array of void pointers which becomes the value of a Capsule. The header file corresponding to the module provides a macro that takes care of importing the module and retrieving its C API pointers; client modules only have to call this macro before accessing the C API.

The exporting module is a modification of the `spam` module from section [A Simple Example](#). The function `spam.system()` does not call the C library function `system()` directly, but a function

**PySpam\_System()**, which would of course do something more complicated in reality (such as adding “spam” to every command). This function **PySpam\_System()** is also exported to other extension modules.

The function **PySpam\_System()** is a plain C function, declared `static` like everything else:

```
static int
PySpam_System(const char *command)
{
    return system(command);
}
```

The function **spam\_system()** is modified in a trivial way:

```
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = PySpam_System(command);
    return PyLong_FromLong(sts);
}
```

In the beginning of the module, right after the line

```
#include <Python.h>
```

two more lines must be added:

```
#define SPAM_MODULE
#include "spammodule.h"
```

The `#define` is used to tell the header file that it is being included in the exporting module, not a client module. Finally, the module’s initialization function must take care of initializing the C API pointer array:

```

PyMODINIT_FUNC
PyInit_spam(void)
{
    PyObject *m;
    static void *PySpam_API[PySpam_API_pointers];
    PyObject *c_api_object;

    m = PyModule_Create(&spammodule);
    if (m == NULL)
        return NULL;

    /* Initialize the C API pointer array */
    PySpam_API[PySpam_System_NUM] = (void *)PySpam_System;

    /* Create a Capsule containing the API pointer array */
    c_api_object = PyCapsule_New((void *)PySpam_API, "spammodule._C_API", NULL);

    if (PyModule_AddObject(m, "_C_API", c_api_object) < 0)
        Py_XDECREF(c_api_object);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}

```

Note that `PySpam_API` is declared `static`; otherwise the pointer array would disappear when **`PyInit_spam()`** terminates!

The bulk of the work is in the header file `spammodule.h`, which looks like this:

```

#ifndef Py_SPAMMODULE_H
#define Py_SPAMMODULE_H
#ifdef __cplusplus
extern "C" {
#endif

/* Header file for spammodule */

```

```

/* C API functions */
#define PySpam_System_NUM 0
#define PySpam_System_RETURN int
#define PySpam_System_PROTO (const char *command)

/* Total number of C API pointers */
#define PySpam_API_pointers 1

#ifdef SPAM_MODULE
/* This section is used when compiling spammodule.c */

static PySpam_System_RETURN PySpam_System PySpam_System_

#else
/* This section is used in modules that use spammodule's

static void **PySpam_API;

#define PySpam_System \
    (*(PySpam_System_RETURN (*)PySpam_System_PROTO) PySpam_

/* Return -1 on error, 0 on success.
 * PyCapsule_Import will set an exception if there's an
 */
static int
import_spam(void)
{
    PySpam_API = (void **)PyCapsule_Import("spam._C_API")
    return (PySpam_API != NULL) ? 0 : -1;
}

#endif

#ifdef __cplusplus
}
#endif

```

```
#endif /* !defined(Py_SPAMMODULE_H) */
```

All that a client module must do in order to have access to the function **PySpam\_System()** is to call the function (or rather macro) **import\_spam()** in its initialization function:

```
PyMODINIT_FUNC
PyInit_client(void)
{
    PyObject *m;

    m = PyModule_Create(&clientmodule);
    if (m == NULL)
        return NULL;
    if (import_spam() < 0)
        return NULL;
    /* additional initialization can happen here */
    return m;
}
```

The main disadvantage of this approach is that the file `spammodule.h` is rather complicated. However, the basic structure is the same for each function that is exported, so it has to be learned only once.

Finally it should be mentioned that Capsules offer additional functionality, which is especially useful for memory allocation and deallocation of the pointer stored in a Capsule. The details are described in the Python/C API Reference Manual in the section [Capsules](#) and in the implementation of Capsules (files `Include/pycapsule.h` and `Objects/pycapsule.c` in the Python source code distribution).

## Footnotes

1

An interface for this function already exists in the standard module **os** — it was chosen as a simple and straightforward

example.

2

The metaphor of “borrowing” a reference is not completely correct: the owner still has a copy of the reference.

3

Checking that the reference count is at least 1 **does not work** — the reference count itself could be in freed memory and may thus be reused for another object!

4

These guarantees don’t hold when you use the “old” style calling convention — this is still found in much existing code.

## 2. Defining Extension Types: Tutorial

Python allows the writer of a C extension module to define new types that can be manipulated from Python code, much like the built-in `str` and `list` types. The code for all extension types follows a pattern, but there are some details that you need to understand before you can get started. This document is a gentle introduction to the topic.

### 2.1. The Basics

The CPython runtime sees all Python objects as variables of type `PyObject*`, which serves as a “base type” for all Python objects. The `PyObject` structure itself only contains the object’s `reference count` and a pointer to the object’s “type object”. This is where the action is; the type object determines which (C) functions get called by the interpreter when, for instance, an attribute gets looked up on an object, a method called, or it is multiplied by another object. These C functions are called “type methods”.

So, if you want to define a new extension type, you need to create a new type object.

This sort of thing can only be explained by example, so here’s a minimal, but complete, module that defines a new type named `Custom` inside a C extension module `custom`:

#### Note

What we’re showing here is the traditional way of defining *static* extension types. It should be adequate for most uses. The C API also allows defining heap-allocated extension types using the `PyType_FromSpec()` function, which isn’t covered in this

## tutorial.

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>

typedef struct {
    PyObject_HEAD
    /* Type-specific fields go here. */
} CustomObject;

static PyTypeObject CustomType = {
    .ob_base = PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "custom.Custom",
    .tp_doc = PyDoc_STR("Custom objects"),
    .tp_basicsize = sizeof(CustomObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT,
    .tp_new = PyType_GenericNew,
};

static PyModuleDef custommodule = {
    .m_base = PyModuleDef_HEAD_INIT,
    .m_name = "custom",
    .m_doc = "Example module that creates an extension t",
    .m_size = -1,
};

PyMODINIT_FUNC
PyInit_custom(void)
{
    PyObject *m;
    if (PyType_Ready(&CustomType) < 0)
        return NULL;

    m = PyModule_Create(&custommodule);
    if (m == NULL)
        return NULL;
```

```

Py_INCREF (&CustomType);
if (PyModule_AddObject(m, "Custom", (PyObject *) &Cu
    Py_DECREF (&CustomType);
    Py_DECREF (m);
    return NULL;
}

return m;
}

```

Now that's quite a bit to take in at once, but hopefully bits will seem familiar from the previous chapter. This file defines three things:

1. What a **Custom object** contains: this is the `CustomObject` struct, which is allocated once for each **Custom** instance.
2. How the **Custom type** behaves: this is the `CustomType` struct, which defines a set of flags and function pointers that the interpreter inspects when specific operations are requested.
3. How to initialize the **custom** module: this is the `PyInit_custom` function and the associated `custommodule` struct.

The first bit is:

```

typedef struct {
    PyObject_HEAD
} CustomObject;

```

This is what a Custom object will contain. `PyObject_HEAD` is mandatory at the start of each object struct and defines a field called `ob_base` of type **PyObject**, containing a pointer to a type object and a reference count (these can be accessed using the macros **Py\_TYPE** and **Py\_REFCNT** respectively). The reason for the macro is to abstract away the layout and to enable additional fields in **debug builds**.

## Note

There is no semicolon above after the `PyObject_HEAD` macro. Be wary of adding one by accident: some compilers will complain.

Of course, objects generally store additional data besides the standard `PyObject_HEAD` boilerplate; for example, here is the definition for standard Python floats:

```
typedef struct {
    PyObject_HEAD
    double ob_fval;
} PyFloatObject;
```

The second bit is the definition of the type object.

```
static PyTypeObject CustomType = {
    .ob_base = PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "custom.Custom",
    .tp_doc = PyDoc_STR("Custom objects"),
    .tp_basicsize = sizeof(CustomObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT,
    .tp_new = PyType_GenericNew,
};
```

## Note

We recommend using C99-style designated initializers as above, to avoid listing all the `PyTypeObject` fields that you don't care about and also to avoid caring about the fields' declaration order.

The actual definition of `PyTypeObject` in `object.h` has many more fields than the definition above. The remaining fields will be filled with zeros by the C compiler, and it's common practice to not specify them explicitly unless you need them.

We're going to pick it apart, one field at a time:

```
.ob_base = PyVarObject_HEAD_INIT(NULL, 0)
```

This line is mandatory boilerplate to initialize the `ob_base` field mentioned above.

```
.tp_name = "custom.Custom",
```

The name of our type. This will appear in the default textual representation of our objects and in some error messages, for example:

```
>>> "" + custom.Custom()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: can only concatenate str (not "custom.Custom")
```

Note that the name is a dotted name that includes both the module name and the name of the type within the module. The module in this case is `custom` and the type is `Custom`, so we set the type name to `custom.Custom`. Using the real dotted import path is important to make your type compatible with the [pydoc](#) and [pickle](#) modules.

```
.tp_basicsize = sizeof(CustomObject),
.tp_itemsize = 0,
```

This is so that Python knows how much memory to allocate when creating new `Custom` instances. `tp_itemsize` is only used for variable-sized objects and should otherwise be zero.

## Note

If you want your type to be subclassable from Python, and your type has the same `tp_basicsize` as its base type, you may have problems with multiple inheritance. A Python subclass of your type will have to list your type first in its `__bases__`, or else it will not be able to call your type's `__new__()` method without getting an error. You can avoid this problem by ensuring that your type has a larger value for `tp_basicsize` than its base type does. Most of the time, this will be true anyway, because either your base type will be `object`, or else you will

be adding data members to your base type, and therefore increasing its size.

We set the class flags to `Py_TPFLAGS_DEFAULT`.

```
.tp_flags = Py_TPFLAGS_DEFAULT,
```

All types should include this constant in their flags. It enables all of the members defined until at least Python 3.3. If you need further members, you will need to OR the corresponding flags.

We provide a doc string for the type in `tp_doc`.

```
.tp_doc = PyDoc_STR("Custom objects"),
```

To enable object creation, we have to provide a `tp_new` handler. This is the equivalent of the Python method `__new__()`, but has to be specified explicitly. In this case, we can just use the default implementation provided by the API function `PyType_GenericNew()`.

```
.tp_new = PyType_GenericNew,
```

Everything else in the file should be familiar, except for some code in `PyInit_custom()`:

```
if (PyType_Ready(&CustomType) < 0)
    return;
```

This initializes the `Custom` type, filling in a number of members to the appropriate default values, including `ob_type` that we initially set to `NULL`.

```
Py_INCREF(&CustomType);
if (PyModule_AddObject(m, "Custom", (PyObject *) &CustomType) < 0)
    Py_DECREF(&CustomType);
    Py_DECREF(m);
    return NULL;
}
```

This adds the type to the module dictionary. This allows us to

create **Custom** instances by calling the **Custom** class:

```
>>> import custom
>>> mycustom = custom.Custom()
```

That's it! All that remains is to build it; put the above code in a file called `custom.c`,

```
[build-system]
requires = ["setuptools"]
build-backend = "setuptools.build_meta"
```

```
[project]
name = "custom"
version = "1"
```

in a file called `pyproject.toml`, and

```
from setuptools import Extension, setup
setup(ext_modules=[Extension("custom", ["custom.c"])]])
```

in a file called `setup.py`; then typing

```
$ python -m pip install .
```

in a shell should produce a file `custom.so` in a subdirectory and install it; now fire up Python — you should be able to `import custom` and play around with `Custom` objects.

That wasn't so hard, was it?

Of course, the current `Custom` type is pretty uninteresting. It has no data and doesn't do anything. It can't even be subclassed.

## 2.2. Adding data and methods to the Basic example

Let's extend the basic example to add some data and methods. Let's also make the type usable as a base class. We'll create a new module, **custom2** that adds these capabilities:

```

#define PY_SSIZE_T_CLEAN
#include <Python.h>
#include <stddef.h> /* for offsetof() */

typedef struct {
    PyObject_HEAD
    PyObject *first; /* first name */
    PyObject *last;  /* last name */
    int number;
} CustomObject;

static void
Custom_dealloc(CustomObject *self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    Py_TYPE(self)->tp_free((PyObject *) self);
}

static PyObject *
Custom_new(PyTypeObject *type, PyObject *args, PyObject
{
    CustomObject *self;
    self = (CustomObject *) type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyUnicode_FromString("");
        if (self->last == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->number = 0;
    }
    return (PyObject *) self;
}

```

```

}

static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|OOi",
                                     &first, &last,
                                     &self->number))
        return -1;

    if (first) {
        Py_XSETREF(self->first, Py_NewRef(first));
    }
    if (last) {
        Py_XSETREF(self->last, Py_NewRef(last));
    }
    return 0;
}

static PyMemberDef Custom_members[] = {
    {"first", Py_T_OBJECT_EX, offsetof(CustomObject, first),
     "first name"},
    {"last", Py_T_OBJECT_EX, offsetof(CustomObject, last),
     "last name"},
    {"number", Py_T_INT, offsetof(CustomObject, number),
     "custom number"},
    {NULL} /* Sentinel */
};

static PyObject *
Custom_name(CustomObject *self, PyObject *Py_UNUSED(ignored))
{
    if (self->first == NULL) {
        PyErr_SetString(PyExc_AttributeError, "first");
        return NULL;
    }

```

```

    }
    if (self->last == NULL) {
        PyErr_SetString(PyExc_AttributeError, "last");
        return NULL;
    }
    return PyUnicode_FromFormat("%S %S", self->first, se
}

static PyMethodDef Custom_methods[] = {
    {"name", (PyCFunction) Custom_name, METH_NOARGS,
     "Return the name, combining the first and last name
    },
    {NULL} /* Sentinel */
};

static PyTypeObject CustomType = {
    .ob_base = PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "custom2.Custom",
    .tp_doc = PyDoc_STR("Custom objects"),
    .tp_basicsize = sizeof(CustomObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE
    .tp_new = Custom_new,
    .tp_init = (initproc) Custom_init,
    .tp_dealloc = (destructor) Custom_dealloc,
    .tp_members = Custom_members,
    .tp_methods = Custom_methods,
};

static PyModuleDef custommodule = {
    .m_base =PyModuleDef_HEAD_INIT,
    .m_name = "custom2",
    .m_doc = "Example module that creates an extension t
    .m_size = -1,
};

PyMODINIT_FUNC
PyInit_custom2(void)

```

```

{
    PyObject *m;
    if (PyType_Ready(&CustomType) < 0)
        return NULL;

    m = PyModule_Create(&custommodule);
    if (m == NULL)
        return NULL;

    if (PyModule_AddObjectRef(m, "Custom", (PyObject *)
        Py_DECREF(m);
        return NULL;
    }

    return m;
}

```

This version of the module has a number of changes.

The **Custom** type now has three data attributes in its C struct, *first*, *last*, and *number*. The *first* and *last* variables are Python strings containing first and last names. The *number* attribute is a C integer.

The object structure is updated accordingly:

```

typedef struct {
    PyObject_HEAD
    PyObject *first; /* first name */
    PyObject *last;  /* last name */
    int number;
} CustomObject;

```

Because we now have data to manage, we have to be more careful about object allocation and deallocation. At a minimum, we need a deallocation method:

```

static void
Custom_dealloc(CustomObject *self)
{
    Py_XDECREF(self->first);
}

```

```

    Py_XDECREF(self->last);
    Py_TYPE(self)->tp_free((PyObject *) self);
}

```

which is assigned to the `tp_dealloc` member:

```

.tp_dealloc = (destructor) Custom_dealloc,

```

This method first clears the reference counts of the two Python attributes. `Py_XDECREF()` correctly handles the case where its argument is `NULL` (which might happen here if `tp_new` failed midway). It then calls the `tp_free` member of the object's type (computed by `Py_TYPE(self)`) to free the object's memory. Note that the object's type might not be `CustomType`, because the object may be an instance of a subclass.

## Note

The explicit cast to `destructor` above is needed because we defined `Custom_dealloc` to take a `CustomObject *` argument, but the `tp_dealloc` function pointer expects to receive a `PyObject *` argument. Otherwise, the compiler will emit a warning. This is object-oriented polymorphism, in C!

We want to make sure that the first and last names are initialized to empty strings, so we provide a `tp_new` implementation:

```

static PyObject *
Custom_new(PyTypeObject *type, PyObject *args, PyObject
{
    CustomObject *self;
    self = (CustomObject *) type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyUnicode_FromString("");
    }
}

```

```

        if (self->last == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->number = 0;
    }
    return (PyObject *) self;
}

```

and install it in the `tp_new` member:

```

.tp_new = Custom_new,

```

The `tp_new` handler is responsible for creating (as opposed to initializing) objects of the type. It is exposed in Python as the `__new__()` method. It is not required to define a `tp_new` member, and indeed many extension types will simply reuse `PyType_GenericNew()` as done in the first version of the `Custom` type above. In this case, we use the `tp_new` handler to initialize the `first` and `last` attributes to non-NULL default values.

`tp_new` is passed the type being instantiated (not necessarily `CustomType`, if a subclass is instantiated) and any arguments passed when the type was called, and is expected to return the instance created. `tp_new` handlers always accept positional and keyword arguments, but they often ignore the arguments, leaving the argument handling to initializer (a.k.a. `tp_init` in C or `__init__` in Python) methods.

## Note

`tp_new` shouldn't call `tp_init` explicitly, as the interpreter will do it itself.

The `tp_new` implementation calls the `tp_alloc` slot to allocate memory:

```

self = (CustomObject *) type->tp_alloc(type, 0);

```

Since memory allocation may fail, we must check the `tp_alloc` result against `NULL` before proceeding.

## Note

We didn't fill the `tp_alloc` slot ourselves. Rather `PyType_Ready()` fills it for us by inheriting it from our base class, which is `object` by default. Most types use the default allocation strategy.

## Note

If you are creating a co-operative `tp_new` (one that calls a base type's `tp_new` or `__new__()`), you must *not* try to determine what method to call using method resolution order at runtime. Always statically determine what type you are going to call, and call its `tp_new` directly, or via `type->tp_base->tp_new`. If you do not do this, Python subclasses of your type that also inherit from other Python-defined classes may not work correctly. (Specifically, you may not be able to create instances of such subclasses without getting a `TypeError`.)

We also define an initialization function which accepts arguments to provide initial values for our instance:

```
static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL, *tmp;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|OOi",
                                     &first, &last,
                                     &self->number))

        return -1;

    if (first) {
        tmp = self->first;
```

```

        Py_INCREF(first);
        self->first = first;
        Py_XDECREF(tmp);
    }
    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_XDECREF(tmp);
    }
    return 0;
}

```

by filling the `tp_init` slot.

```
.tp_init = (initproc) Custom_init,
```

The `tp_init` slot is exposed in Python as the `__init__()` method. It is used to initialize an object after it's created. Initializers always accept positional and keyword arguments, and they should return either 0 on success or -1 on error.

Unlike the `tp_new` handler, there is no guarantee that `tp_init` is called at all (for example, the `pickle` module by default doesn't call `__init__()` on unpickled instances). It can also be called multiple times. Anyone can call the `__init__()` method on our objects. For this reason, we have to be extra careful when assigning the new attribute values. We might be tempted, for example to assign the `first` member like this:

```

if (first) {
    Py_XDECREF(self->first);
    Py_INCREF(first);
    self->first = first;
}

```

But this would be risky. Our type doesn't restrict the type of the `first` member, so it could be any kind of object. It could have a destructor that causes code to be executed that tries to access the `first` member; or that destructor could release the `Global`

[interpreter Lock](#) and let arbitrary code run in other threads that accesses and modifies our object.

To be paranoid and protect ourselves against this possibility, we almost always reassign members before decrementing their reference counts. When don't we have to do this?

- when we absolutely know that the reference count is greater than 1;
- when we know that deallocation of the object [1](#) will neither release the [GIL](#) nor cause any calls back into our type's code;
- when decrementing a reference count in a [tp\\_dealloc](#) handler on a type which doesn't support cyclic garbage collection [2](#).

We want to expose our instance variables as attributes. There are a number of ways to do that. The simplest way is to define member definitions:

```
static PyMemberDef Custom_members[] = {
    {"first", Py_T_OBJECT_EX, offsetof(CustomObject, first),
     "first name"},
    {"last", Py_T_OBJECT_EX, offsetof(CustomObject, last),
     "last name"},
    {"number", Py_T_INT, offsetof(CustomObject, number),
     "custom number"},
    {NULL} /* Sentinel */
};
```

and put the definitions in the [tp\\_members](#) slot:

```
.tp_members = Custom_members,
```

Each member definition has a member name, type, offset, access flags and documentation string. See the [Generic Attribute Management](#) section below for details.

A disadvantage of this approach is that it doesn't provide a way to restrict the types of objects that can be assigned to the Python attributes. We expect the first and last names to be strings, but any Python objects can be assigned. Further, the attributes can be

deleted, setting the C pointers to `NULL`. Even though we can make sure the members are initialized to non-`NULL` values, the members can be set to `NULL` if the attributes are deleted.

We define a single method, `Custom.name()`, that outputs the objects name as the concatenation of the first and last names.

```
static PyObject *
Custom_name(CustomObject *self, PyObject *Py_UNUSED(ignore))
{
    if (self->first == NULL) {
        PyErr_SetString(PyExc_AttributeError, "first");
        return NULL;
    }
    if (self->last == NULL) {
        PyErr_SetString(PyExc_AttributeError, "last");
        return NULL;
    }
    return PyUnicode_FromFormat("%S %S", self->first, self->last);
}
```

The method is implemented as a C function that takes a `Custom` (or `Custom` subclass) instance as the first argument. Methods always take an instance as the first argument. Methods often take positional and keyword arguments as well, but in this case we don't take any and don't need to accept a positional argument tuple or keyword argument dictionary. This method is equivalent to the Python method:

```
def name(self):
    return "%s %s" % (self.first, self.last)
```

Note that we have to check for the possibility that our `first` and `last` members are `NULL`. This is because they can be deleted, in which case they are set to `NULL`. It would be better to prevent deletion of these attributes and to restrict the attribute values to be strings. We'll see how to do that in the next section.

Now that we've defined the method, we need to create an array of method definitions:

```
static PyMethodDef Custom_methods[] = {
    {"name", (PyCFunction) Custom_name, METH_NOARGS,
     "Return the name, combining the first and last name"},
    {NULL} /* Sentinel */
};
```

(note that we used the `METH_NOARGS` flag to indicate that the method is expecting no arguments other than *self*)

and assign it to the `tp_methods` slot:

```
.tp_methods = Custom_methods,
```

Finally, we'll make our type usable as a base class for subclassing. We've written our methods carefully so far so that they don't make any assumptions about the type of the object being created or used, so all we need to do is to add the `Py_TPFLAGS_BASETYPE` to our class flag definition:

```
.tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE,
```

We rename `PyInit_custom()` to `PyInit_custom2()`, update the module name in the `PyModuleDef` struct, and update the full class name in the `PyTypeObject` struct.

Finally, we update our `setup.py` file to include the new module,

```
from setuptools import Extension, setup
setup(ext_modules=[
    Extension("custom", ["custom.c"]),
    Extension("custom2", ["custom2.c"]),
])
```

and then we re-install so that we can `import custom2`:

```
$ python -m pip install .
```

## 2.3. Providing finer control over data attributes

In this section, we'll provide finer control over how the **first** and **last** attributes are set in the **Custom** example. In the previous version of our module, the instance variables **first** and **last** could be set to non-string values or even deleted. We want to make sure that these attributes always contain strings.

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>
#include <stddef.h> /* for offsetof() */

typedef struct {
    PyObject_HEAD
    PyObject *first; /* first name */
    PyObject *last;  /* last name */
    int number;
} CustomObject;

static void
Custom_dealloc(CustomObject *self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    Py_TYPE(self)->tp_free((PyObject *) self);
}

static PyObject *
Custom_new(PyTypeObject *type, PyObject *args, PyObject
{
    CustomObject *self;
    self = (CustomObject *) type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyUnicode_FromString("");
        if (self->last == NULL) {
            Py_DECREF(self);
```

```

        return NULL;
    }
    self->number = 0;
}
return (PyObject *) self;
}

static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|UUi",
                                     &first, &last,
                                     &self->number))
        return -1;

    if (first) {
        Py_SETREF(self->first, Py_NewRef(first));
    }
    if (last) {
        Py_SETREF(self->last, Py_NewRef(last));
    }
    return 0;
}

static PyMemberDef Custom_members[] = {
    {"number", Py_T_INT, offsetof(CustomObject, number),
    "custom number"},
    {NULL} /* Sentinel */
};

static PyObject *
Custom_getfirst(CustomObject *self, void *closure)
{
    return Py_NewRef(self->first);
}

```

```

static int

    return m;
}

```

To provide greater control, over the **first** and **last** attributes, we'll use custom getter and setter functions. Here are the functions for getting and setting the **first** attribute:

```

static PyObject *
Custom_getfirst(CustomObject *self, void *closure)
{
    Py_INCREF(self->first);
    return self->first;
}

```

static int

```

Custom_setfirst(CustomObject *self, PyObject *value, voi
{

```

```

PyObject *tmp;
if (value == NULL) {
    PyErr_SetString(PyExc_TypeError, "Cannot delete
    return -1;
}
if (!PyUnicode_Check(value)) {
    PyErr_SetString(PyExc_TypeError,
        "The first attribute value must
    return -1;
}
tmp = self->first;
Py_INCREF(value);
self->first = value;
Py_DECREF(tmp);
return 0;
}

```

The getter function is passed a **Custom** object and a “closure”, which is a void pointer. In this case, the closure is ignored. (The closure supports an advanced usage in which definition data is passed to the getter and setter. This could, for example, be used to allow a single set of getter and setter functions that decide the attribute to get or set based on data in the closure.)

The setter function is passed the **Custom** object, the new value, and the closure. The new value may be `NULL`, in which case the attribute is being deleted. In our setter, we raise an error if the attribute is deleted or if its new value is not a string.

We create an array of **PyGetSetDef** structures:

```

static PyGetSetDef Custom_getsetters[] = {
    {"first", (getter) Custom_getfirst, (setter) Custom_
    "first name", NULL},
    {"last", (getter) Custom_getlast, (setter) Custom_se
    "last name", NULL},
    {NULL} /* Sentinel */
};

```

and register it in the **tp\_getset** slot:

```
.tp_getset = Custom_getsetters,
```

The last item in a **PyGetSetDef** structure is the “closure” mentioned above. In this case, we aren’t using a closure, so we just pass `NULL`.

We also remove the member definitions for these attributes:

```
static PyMemberDef Custom_members[] = {
    {"number", Py_T_INT, offsetof(CustomObject, number),
     "custom number"},
    {NULL} /* Sentinel */
};
```

We also need to update the **tp\_init** handler to only allow strings **3** to be passed:

```
static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL, *tmp;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|UUi",
                                     &first, &last,
                                     &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_DECREF(tmp);
    }
    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }
}
```

```
    return 0;
}
```

With these changes, we can assure that the `first` and `last` members are never `NULL` so we can remove checks for `NULL` values in almost all cases. This means that most of the `Py_XDECREF()` calls can be converted to `Py_DECREF()` calls. The only place we can't change these calls is in the `tp_dealloc` implementation, where there is the possibility that the initialization of these members failed in `tp_new`.

We also rename the module initialization function and module name in the initialization function, as we did before, and we add an extra definition to the `setup.py` file.

## 2.4. Supporting cyclic garbage collection

Python has a [cyclic garbage collector \(GC\)](#) that can identify unneeded objects even when their reference counts are not zero. This can happen when objects are involved in cycles. For example, consider:

```
>>> l = []
>>> l.append(l)
>>> del l
```

In this example, we create a list that contains itself. When we delete it, it still has a reference from itself. Its reference count doesn't drop to zero. Fortunately, Python's cyclic garbage collector will eventually figure out that the list is garbage and free it.

In the second version of the `Custom` example, we allowed any kind of object to be stored in the `first` or `last` attributes [4](#). Besides, in the second and third versions, we allowed subclassing `Custom`, and subclasses may add arbitrary attributes. For any of those two reasons, `Custom` objects can participate in cycles:

```
>>> import custom3
>>> class Derived(custom3.Custom): pass
...
```

```
>>> n = Derived()
>>> n.some_attribute = n
```

To allow a **Custom** instance participating in a reference cycle to be properly detected and collected by the cyclic GC, our **Custom** type needs to fill two additional slots and to enable a flag that enables these slots:

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>
#include <stddef.h> /* for offsetof() */

typedef struct {
    PyObject_HEAD
    PyObject *first; /* first name */
    PyObject *last;  /* last name */
    int number;
} CustomObject;

static int
Custom_traverse(CustomObject *self, visitproc visit, void *arg)
{
    Py_VISIT(self->first);
    Py_VISIT(self->last);
    return 0;
}

static int
Custom_clear(CustomObject *self)
{
    Py_CLEAR(self->first);
    Py_CLEAR(self->last);
    return 0;
}

static void
Custom_dealloc(CustomObject *self)
{
    PyObject_GC_UnTrack(self);
}
```

```

    Custom_clear(self);
    Py_TYPE(self)->tp_free((PyObject *) self);
}

```

```

static PyObject *
Custom_new(PyTypeObject *type, PyObject *args, PyObject
{
    CustomObject *self;
    self = (CustomObject *) type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyUnicode_FromString("");
        if (self->last == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->number = 0;
    }
    return (PyObject *) self;
}

```

```

static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|UUi",
                                     &first, &last,
                                     &self->number))

        return -1;

    if (first) {
        Py_SETREF(self->first, Py_NewRef(first));
    }
}

```

```

    }
    if (last) {
        Py_SETREF(self->last, Py_NewRef(last));
    }
    return 0;
}

```

```

static PyMemberDef Custom_members[] = {
    {"number", Py_T_INT, offsetof(CustomObject, number),
     "custom number"},
    {NULL} /* Sentinel */
};

```

```

static PyObject *
Custom_getfirst(CustomObject *self, void *closure)
{
    return Py_NewRef(self->first);
}

```

```

static int
Custom_setfirst(CustomObject *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete attribute");
        return -1;
    }
    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError,
                        "The first attribute value must be a string");
        return -1;
    }
    Py_XSETREF(self->first, Py_NewRef(value));
    return 0;
}

```

```

static PyObject *
Custom_getlast(CustomObject *self, void *closure)
{

```

```

        return Py_NewRef(self->last);
    }

static int
Custom_setlast(CustomObject *self, PyObject *value, void *)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete attribute");
        return -1;
    }
    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError,
                        "The last attribute value must be a string");
        return -1;
    }
    Py_XSETREF(self->last, Py_NewRef(value));
    return 0;
}

static PyGetSetDef Custom_getsetters[] = {
    {"first", (getter) Custom_getfirst, (setter) Custom_setfirst,
     "first name", NULL},
    {"last", (getter) Custom_getlast, (setter) Custom_setlast,
     "last name", NULL},
    {NULL} /* Sentinel */
};

static PyObject *
Custom_name(CustomObject *self, PyObject *Py_UNUSED(ignored))
{
    return PyUnicode_FromFormat("%S %S", self->first, self->last);
}

static PyMethodDef Custom_methods[] = {
    {"name", (PyCFunction) Custom_name, METH_NOARGS,
     "Return the name, combining the first and last name"},
    {NULL} /* Sentinel */
};

```

```
};
```

```
static PyTypeObject CustomType = {  
    .ob_base = PyVarObject_HEAD_INIT(NULL, 0)  
    .tp_name = "custom4.Custom",  
    .tp_doc = PyDoc_STR("Custom objects"),  
    .tp_basicsize = sizeof(CustomObject),  
    .tp_itemsize = 0,  
    .tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE  
    .tp_new = Custom_new,  
    .tp_init = (initproc) Custom_init,  
    .tp_dealloc = (destructor) Custom_dealloc,  
    .tp_traverse = (traverseproc) Custom_traverse,  
    .tp_clear = (inquiry) Custom_clear,  
    .tp_members = Custom_members,  
    .tp_methods = Custom_methods,  
    .tp_getset = Custom_getsetters,  
};
```

```
static PyModuleDef custommodule = {  
    .m_base = PyModuleDef_HEAD_INIT,  
    .m_name = "custom4",  
    .m_doc = "Example module that creates an extension t  
    .m_size = -1,  
};
```

```
PyMODINIT_FUNC
```

```
PyInit_custom4(void)
```

```
{  
    PyObject *m;  
    if (PyType_Ready(&CustomType) < 0)  
        return NULL;  
  
    m = PyModule_Create(&custommodule);  
    if (m == NULL)  
        return NULL;  
  
    if (PyModule_AddObjectRef(m, "Custom", (PyObject *)
```

```

        Py_DECREF(m);
        return NULL;
    }

    return m;
}

```

First, the traversal method lets the cyclic GC know about subobjects that could participate in cycles:

```

static int
Custom_traverse(CustomObject *self, visitproc visit, void *arg)
{
    int vret;
    if (self->first) {
        vret = visit(self->first, arg);
        if (vret != 0)
            return vret;
    }
    if (self->last) {
        vret = visit(self->last, arg);
        if (vret != 0)
            return vret;
    }
    return 0;
}

```

For each subobject that can participate in cycles, we need to call the **visit()** function, which is passed to the traversal method. The **visit()** function takes as arguments the subobject and the extra argument *arg* passed to the traversal method. It returns an integer value that must be returned if it is non-zero.

Python provides a **Py\_VISIT()** macro that automates calling visit functions. With **Py\_VISIT()**, we can minimize the amount of boilerplate in `Custom_traverse`:

```

static int
Custom_traverse(CustomObject *self, visitproc visit, void *arg)
{

```

```

    Py_VISIT(self->first);
    Py_VISIT(self->last);
    return 0;
}

```

## Note

The `tp_traverse` implementation must name its arguments exactly *visit* and *arg* in order to use `Py_VISIT()`.

Second, we need to provide a method for clearing any subobjects that can participate in cycles:

```

static int
Custom_clear(CustomObject *self)
{
    Py_CLEAR(self->first);
    Py_CLEAR(self->last);
    return 0;
}

```

Notice the use of the `Py_CLEAR()` macro. It is the recommended and safe way to clear data attributes of arbitrary types while decrementing their reference counts. If you were to call `Py_XDECREF()` instead on the attribute before setting it to `NULL`, there is a possibility that the attribute's destructor would call back into code that reads the attribute again (*especially* if there is a reference cycle).

## Note

You could emulate `Py_CLEAR()` by writing:

```

PyObject *tmp;
tmp = self->first;
self->first = NULL;
Py_XDECREF(tmp);

```

Nevertheless, it is much easier and less error-prone to always use

`Py_CLEAR()` when deleting an attribute. Don't try to micro-optimize at the expense of robustness!

The deallocator `Custom_dealloc` may call arbitrary code when clearing attributes. It means the circular GC can be triggered inside the function. Since the GC assumes reference count is not zero, we need to untrack the object from the GC by calling `PyObject_GC_UnTrack()` before clearing members. Here is our reimplemented deallocator using `PyObject_GC_UnTrack()` and `Custom_clear`:

```
static void
Custom_dealloc(CustomObject *self)
{
    PyObject_GC_UnTrack(self);
    Custom_clear(self);
    Py_TYPE(self)->tp_free((PyObject *) self);
}
```

Finally, we add the `Py_TPFLAGS_HAVE_GC` flag to the class flags:

```
.tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE | Py_TPFLAGS_HAVE_GC
```

That's pretty much it. If we had written custom `tp_alloc` or `tp_free` handlers, we'd need to modify them for cyclic garbage collection. Most extensions will use the versions automatically provided.

## 2.5. Subclassing other types

It is possible to create new extension types that are derived from existing types. It is easiest to inherit from the built in types, since an extension can easily use the `PyTypeObject` it needs. It can be difficult to share these `PyTypeObject` structures between extension modules.

In this example we will create a `SubList` type that inherits from the built-in `list` type. The new type will be completely compatible with regular lists, but will have an additional `increment()` method that increases an internal counter:

```

>>> import sublist
>>> s = sublist.SubList(range(3))
>>> s.extend(s)
>>> print(len(s))
6
>>> print(s.increment())
1
>>> print(s.increment())
2

#define PY_SSIZE_T_CLEAN
#include <Python.h>

typedef struct {
    PyListObject list;
    int state;
} SubListObject;

static PyObject *
SubList_increment(SubListObject *self, PyObject *unused)
{
    self->state++;
    return PyLong_FromLong(self->state);
}

static PyMethodDef SubList_methods[] = {
    {"increment", (PyCFunction) SubList_increment, METH_NOARGS,
     PyDoc_STR("increment state counter")},
    {NULL},
};

static int
SubList_init(SubListObject *self, PyObject *args, PyObject *kwargs)
{
    if (PyList_Type.tp_init((PyObject *) self, args, kwargs) != 0)
        return -1;
    self->state = 0;
    return 0;
}

```

```

static PyTypeObject SubListType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "sublist.SubList",
    .tp_doc = PyDoc_STR("SubList objects"),
    .tp_basicsize = sizeof(SubListObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE,
    .tp_init = (initproc) SubList_init,
    .tp_methods = SubList_methods,
};

static PyModuleDef sublistmodule = {
    PyModuleDef_HEAD_INIT,
    .m_name = "sublist",
    .m_doc = "Example module that creates an extension t
    .m_size = -1,
};

PyMODINIT_FUNC
PyInit_sublist(void)
{
    PyObject *m;
    SubListType.tp_base = &PyList_Type;
    if (PyType_Ready(&SubListType) < 0)
        return NULL;

    m = PyModule_Create(&sublistmodule);
    if (m == NULL)
        return NULL;

    Py_INCREF(&SubListType);
    if (PyModule_AddObject(m, "SubList", (PyObject *) &S
        Py_DECREF(&SubListType);
        Py_DECREF(m);
        return NULL;
}

```

```

    return m;
}

```

As you can see, the source code closely resembles the **Custom** examples in previous sections. We will break down the main differences between them.

```

typedef struct {
    PyListObject list;
    int state;
} SubListObject;

```

The primary difference for derived type objects is that the base type's object structure must be the first value. The base type will already include the `PyObject_HEAD()` at the beginning of its structure.

When a Python object is a **SubList** instance, its `PyObject *` pointer can be safely cast to both `PyListObject *` and `SubListObject *`:

```

static int
SubList_init(SubListObject *self, PyObject *args, PyObject
{
    if (PyList_Type.tp_init((PyObject *) self, args, kwo
        return -1;
    self->state = 0;
    return 0;
}

```

We see above how to call through to the `__init__()` method of the base type.

This pattern is important when writing a type with custom `tp_new` and `tp_dealloc` members. The `tp_new` handler should not actually create the memory for the object with its `tp_alloc`, but let the base class handle it by calling its own `tp_new`.

The `PyTypeObject` struct supports a `tp_base` specifying the type's concrete base class. Due to cross-platform compiler issues, you can't fill that field directly with a reference to `PyList_Type`;

it should be done later in the module initialization function:

```
PyMODINIT_FUNC
PyInit_sublist(void)
{
    PyObject* m;
    SubListType.tp_base = &PyList_Type;
    if (PyType_Ready(&SubListType) < 0)
        return NULL;

    m = PyModule_Create(&sublistmodule);
    if (m == NULL)
        return NULL;

    Py_INCREF(&SubListType);
    if (PyModule_AddObject(m, "SubList", (PyObject *) &SubListType) < 0)
        Py_DECREF(&SubListType);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

Before calling `PyType_Ready()`, the type structure must have the `tp_base` slot filled in. When we are deriving an existing type, it is not necessary to fill out the `tp_alloc` slot with `PyType_GenericNew()` – the allocation function from the base type will be inherited.

After that, calling `PyType_Ready()` and adding the type object to the module is the same as with the basic **Custom** examples.

## Footnotes

1

This is true when we know that the object is a basic type, like a string or a float.

2

We relied on this in the `tp_dealloc` handler in this example, because our type doesn't support garbage collection.

3

We now know that the first and last members are strings, so perhaps we could be less careful about decrementing their reference counts, however, we accept instances of string subclasses. Even though deallocating normal strings won't call back into our objects, we can't guarantee that deallocating an instance of a string subclass won't call back into our objects.

4

Also, even with our attributes restricted to strings instances, the user could pass arbitrary `str` subclasses and therefore still create reference cycles.

## 3. Defining Extension Types: Assorted Topics

This section aims to give a quick fly-by on the various type methods you can implement and what they do.

Here is the definition of `PyTypeObject`, with some fields only used in `debug builds` omitted:

```
typedef struct _typeobject {
    PyObject_VAR_HEAD
    const char *tp_name; /* For printing, in format "<mod>.<name>" */
    Py_ssize_t tp_basicsize, tp_itemsize; /* For allocation */

    /* Methods to implement standard operations */

    destructor tp_dealloc;
    Py_ssize_t tp_vectorcall_offset;
    getattrofunc tp_getattr;
    setattrofunc tp_setattr;
    PyAsyncMethods *tp_as_async; /* formerly known as tp_as_async (Python 3.0)
                                   or tp_reserved (Python 2.x) */
    reprfunc tp_repr;

    /* Method suites for standard classes */

    PyNumberMethods *tp_as_number;
    PySequenceMethods *tp_as_sequence;
    PyMappingMethods *tp_as_mapping;

    /* More standard operations (here for binary compatibility)
     *
     * .. deprecated 3.10 ..
     */

    hashfunc tp_hash;
    ternaryfunc tp_call;
```

```

reprfunc tp_str;
getattrofunc tp_getattro;
setattrofunc tp_setattro;

/* Functions to access object as input/output buffer
PyBufferProcs *tp_as_buffer;

/* Flags to define presence of optional/expanded features
unsigned long tp_flags;

const char *tp_doc; /* Documentation string */

/* Assigned meaning in release 2.0 */
/* call function for all accessible objects */
traverseproc tp_traverse;

/* delete references to contained objects */
inquiry tp_clear;

/* Assigned meaning in release 2.1 */
/* rich comparisons */
richcmpfunc tp_richcompare;

/* weak reference enabler */
Py_ssize_t tp_weaklistoffset;

/* Iterators */
getiterfunc tp_iter;
iternextfunc tp_iternext;

/* Attribute descriptor and subclassing stuff */
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
// Strong reference on a heap type, borrowed reference
struct _typeobject *tp_base;
PyObject *tp_dict;
descrgetfunc tp_descr_get;

```

```

descrsetfunc tp_descr_set;
Py_ssize_t tp_dictoffset;
initproc tp_init;
allocfunc tp_alloc;
newfunc tp_new;
freefunc tp_free; /* Low-level free-memory routine */
inquiry tp_is_gc; /* For PyObject_IS_GC */
PyObject *tp_bases;
PyObject *tp_mro; /* method resolution order */
PyObject *tp_cache;
PyObject *tp_subclasses;
PyObject *tp_weaklist;
destructor tp_del;

/* Type attribute cache version tag. Added in version 3.0 */
unsigned int tp_version_tag;

destructor tp_finalize;
vectorcallfunc tp_vectorcall;

/* bitset of which type-watchers care about this type */
unsigned char tp_watched;
} PyTypeObject;

```

Now that's a *lot* of methods. Don't worry too much though – if you have a type you want to define, the chances are very good that you will only implement a handful of these.

As you probably expect by now, we're going to go over this and give more information about the various handlers. We won't go in the order they are defined in the structure, because there is a lot of historical baggage that impacts the ordering of the fields. It's often easiest to find an example that includes the fields you need and then change the values to suit your new type.

```
const char *tp_name; /* For printing */
```

The name of the type – as mentioned in the previous chapter, this will appear in various places, almost entirely for diagnostic purposes. Try to choose something that will be helpful in such a

situation!

```
Py_ssize_t tp_basicsize, tp_itemsize; /* For allocation
```

These fields tell the runtime how much memory to allocate when new objects of this type are created. Python has some built-in support for variable length structures (think: strings, tuples) which is where the `tp_itemsize` field comes in. This will be dealt with later.

```
const char *tp_doc;
```

Here you can put a string (or its address) that you want returned when the Python script references `obj.__doc__` to retrieve the doc string.

Now we come to the basic type methods – the ones most extension types will implement.

## 3.1. Finalization and De-allocation

```
destructor tp_dealloc;
```

This function is called when the reference count of the instance of your type is reduced to zero and the Python interpreter wants to reclaim it. If your type has memory to free or other clean-up to perform, you can put it here. The object itself needs to be freed here as well. Here is an example of this function:

```
static void
newdatatype_dealloc(newdatatypeobject *obj)
{
    free(obj->obj_UnderlyingDatatypePtr);
    Py_TYPE(obj)->tp_free((PyObject *)obj);
}
```

If your type supports garbage collection, the destructor should call `PyObject_GC_UnTrack()` before clearing any member fields:

```
static void
```

```

newdatatype_dealloc(newdatatypeobject *obj)
{
    PyObject_GC_UnTrack(obj);
    Py_CLEAR(obj->other_obj);
    ...
    Py_TYPE(obj)->tp_free((PyObject *)obj);
}

```

One important requirement of the deallocator function is that it leaves any pending exceptions alone. This is important since deallocators are frequently called as the interpreter unwinds the Python stack; when the stack is unwound due to an exception (rather than normal returns), nothing is done to protect the deallocators from seeing that an exception has already been set. Any actions which a deallocator performs which may cause additional Python code to be executed may detect that an exception has been set. This can lead to misleading errors from the interpreter. The proper way to protect against this is to save a pending exception before performing the unsafe action, and restoring it when done. This can be done using the [PyErr\\_Fetch\(\)](#) and [PyErr\\_Restore\(\)](#) functions:

```

static void
my_dealloc(PyObject *obj)
{
    PyObject *self = (PyObject *) obj;
    PyObject *cbresult;

    if (self->my_callback != NULL) {
        PyObject *err_type, *err_value, *err_traceback;

        /* This saves the current exception state */
        PyErr_Fetch(&err_type, &err_value, &err_traceback);

        cbresult = PyObject_CallNoArgs(self->my_callback);
        if (cbresult == NULL)
            PyErr_WriteUnraisable(self->my_callback);
        else
            Py_DECREF(cbresult);
    }
}

```

```

        /* This restores the saved exception state */
        PyErr_Restore(err_type, err_value, err_traceback);

        Py_DECREF(self->my_callback);
    }
    Py_TYPE(obj)->tp_free((PyObject*)self);
}

```

## Note

There are limitations to what you can safely do in a deallocator function. First, if your type supports garbage collection (using `tp_traverse` and/or `tp_clear`), some of the object's members can have been cleared or finalized by the time `tp_dealloc` is called. Second, in `tp_dealloc`, your object is in an unstable state: its reference count is equal to zero. Any call to a non-trivial object or API (as in the example above) might end up calling `tp_dealloc` again, causing a double free and a crash.

Starting with Python 3.4, it is recommended not to put any complex finalization code in `tp_dealloc`, and instead use the new `tp_finalize` type method.

## See also

**PEP 442** [<https://peps.python.org/pep-0442/>] explains the new finalization scheme.

## 3.2. Object Presentation

In Python, there are two ways to generate a textual representation of an object: the `repr()` function, and the `str()` function. (The `print()` function just calls `str()`.) These handlers are both optional.

```
reprfunc tp_repr;
reprfunc tp_str;
```

The `tp_repr` handler should return a string object containing a representation of the instance for which it is called. Here is a simple example:

```
static PyObject *
newdatatype_repr(newdatatypeobject *obj)
{
    return PyUnicode_FromFormat("Repr-ified_newdatatype{
                                obj->obj_UnderlyingData");
}
```

If no `tp_repr` handler is specified, the interpreter will supply a representation that uses the type's `tp_name` and a uniquely identifying value for the object.

The `tp_str` handler is to `str()` what the `tp_repr` handler described above is to `repr()`; that is, it is called when Python code calls `str()` on an instance of your object. Its implementation is very similar to the `tp_repr` function, but the resulting string is intended for human consumption. If `tp_str` is not specified, the `tp_repr` handler is used instead.

Here is a simple example:

```
static PyObject *
newdatatype_str(newdatatypeobject *obj)
{
    return PyUnicode_FromFormat("Stringified_newdatatype{
                                obj->obj_UnderlyingData");
}
```

### 3.3. Attribute Management

For every object which can support attributes, the corresponding type must provide the functions that control how the attributes are resolved. There needs to be a function which can retrieve attributes (if any are defined), and another to set attributes (if setting

attributes is allowed). Removing an attribute is a special case, for which the new value passed to the handler is `NULL`.

Python supports two pairs of attribute handlers; a type that supports attributes only needs to implement the functions for one pair. The difference is that one pair takes the name of the attribute as a `char*`, while the other accepts a `PyObject*`. Each type can use whichever pair makes more sense for the implementation's convenience.

```
getattrfunc  tp_getattr;           /* char * version */
setattrfunc  tp_setattr;
/* ... */
getattrofunc tp_getattro;         /* PyObject * version */
setattrofunc tp_setattro;
```

If accessing attributes of an object is always a simple operation (this will be explained shortly), there are generic implementations which can be used to provide the `PyObject*` version of the attribute management functions. The actual need for type-specific attribute handlers almost completely disappeared starting with Python 2.2, though there are many examples which have not been updated to use some of the new generic mechanism that is available.

### 3.3.1. Generic Attribute Management

Most extension types only use *simple* attributes. So, what makes the attributes simple? There are only a couple of conditions that must be met:

1. The name of the attributes must be known when `PyType_Ready()` is called.
2. No special processing is needed to record that an attribute was looked up or set, nor do actions need to be taken based on the value.

Note that this list does not place any restrictions on the values of the attributes, when the values are computed, or how relevant data is stored.

When `PyType_Ready()` is called, it uses three tables referenced

by the type object to create **descriptors** which are placed in the dictionary of the type object. Each descriptor controls access to one attribute of the instance object. Each of the tables is optional; if all three are `NULL`, instances of the type will only have attributes that are inherited from their base type, and should leave the **`tp_getattro`** and **`tp_setattro`** fields `NULL` as well, allowing the base type to handle attributes.

The tables are declared as three fields of the type object:

```
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
```

If **`tp_methods`** is not `NULL`, it must refer to an array of **`PyMethodDef`** structures. Each entry in the table is an instance of this structure:

```
typedef struct PyMethodDef {
    const char *ml_name;           /* method name */
    PyCFunction ml_meth;           /* implementation function */
    int ml_flags;                  /* flags */
    const char *ml_doc;            /* docstring */
} PyMethodDef;
```

One entry should be defined for each method provided by the type; no entries are needed for methods inherited from a base type. One additional entry is needed at the end; it is a sentinel that marks the end of the array. The **`ml_name`** field of the sentinel must be `NULL`.

The second table is used to define attributes which map directly to data stored in the instance. A variety of primitive C types are supported, and access may be read-only or read-write. The structures in the table are defined as:

```
typedef struct PyMemberDef {
    const char *name;
    int type;
    int offset;
    int flags;
```

```
    const char *doc;
} PyMemberDef;
```

For each entry in the table, a **descriptor** will be constructed and added to the type which will be able to extract a value from the instance structure. The **type** field should contain a type code like **Py\_T\_INT** or **Py\_T\_DOUBLE**; the value will be used to determine how to convert Python values to and from C values. The **flags** field is used to store flags which control how the attribute can be accessed: you can set it to **Py\_READONLY** to prevent Python code from setting it.

An interesting advantage of using the **tp\_members** table to build descriptors that are used at runtime is that any attribute defined this way can have an associated doc string simply by providing the text in the table. An application can use the introspection API to retrieve the descriptor from the class object, and get the doc string using its **\_\_doc\_\_** attribute.

As with the **tp\_methods** table, a sentinel entry with a **ml\_name** value of **NULL** is required.

### 3.3.2. Type-specific Attribute Management

For simplicity, only the **char\*** version will be demonstrated here; the type of the name parameter is the only difference between the **char\*** and **PyObject\*** flavors of the interface. This example effectively does the same thing as the generic example above, but does not use the generic support added in Python 2.2. It explains how the handler functions are called, so that if you do need to extend their functionality, you'll understand what needs to be done.

The **tp\_getattr** handler is called when the object requires an attribute look-up. It is called in the same situations where the **\_\_getattr\_\_()** method of a class would be called.

Here is an example:

```
static PyObject *
newdatatype_getattr(newdatatypeobject *obj, char *name)
{
```

```

if (strcmp(name, "data") == 0)
{
    return PyLong_FromLong(obj->data);
}

PyErr_Format(PyExc_AttributeError,
             "'%.100s' object has no attribute '%.40s'",
             Py_TYPE(obj)->tp_name, name);
return NULL;
}

```

The `tp_setattr` handler is called when the `__setattr__()` or `__delattr__()` method of a class instance would be called. When an attribute should be deleted, the third parameter will be `NULL`. Here is an example that simply raises an exception; if this were really all you wanted, the `tp_setattr` handler should be set to `NULL`.

```

static int
newdatatype_setattr(newdatatypeobject *obj, char *name,
{
    PyErr_Format(PyExc_RuntimeError, "Read-only attribute '%s'", name);
    return -1;
}

```

## 3.4. Object Comparison

```
richcmpfunc tp_richcompare;
```

The `tp_richcompare` handler is called when comparisons are needed. It is analogous to the [rich comparison methods](#), like `__lt__()`, and also called by `PyObject_RichCompare()` and `PyObject_RichCompareBool()`.

This function is called with two Python objects and the operator as arguments, where the operator is one of `Py_EQ`, `Py_NE`, `Py_LE`, `Py_GE`, `Py_LT` or `Py_GT`. It should compare the two objects with respect to the specified operator and return `Py_True` or `Py_False` if the comparison is successful, `Py_NotImplemented`

to indicate that comparison is not implemented and the other object's comparison method should be tried, or `NULL` if an exception was set.

Here is a sample implementation, for a datatype that is considered equal if the size of an internal pointer is equal:

```
static PyObject *
newdatatype_richcmp(newdatatypeobject *obj1, newdatatypeobject *obj2,
                    int op)
{
    PyObject *result;
    int c, size1, size2;

    /* code to make sure that both arguments are of type
       newdatatype omitted */

    size1 = obj1->obj_UnderlyingDatatypePtr->size;
    size2 = obj2->obj_UnderlyingDatatypePtr->size;

    switch (op) {
        case Py_LT: c = size1 < size2; break;
        case Py_LE: c = size1 <= size2; break;
        case Py_EQ: c = size1 == size2; break;
        case Py_NE: c = size1 != size2; break;
        case Py_GT: c = size1 > size2; break;
        case Py_GE: c = size1 >= size2; break;
    }
    result = c ? Py_True : Py_False;
    Py_INCREF(result);
    return result;
}
```

## 3.5. Abstract Protocol Support

Python supports a variety of *abstract* ‘protocols,’ the specific interfaces provided to use these interfaces are documented in [Abstract Objects Layer](#).

A number of these abstract interfaces were defined early in the

development of the Python implementation. In particular, the number, mapping, and sequence protocols have been part of Python since the beginning. Other protocols have been added over time. For protocols which depend on several handler routines from the type implementation, the older protocols have been defined as optional blocks of handlers referenced by the type object. For newer protocols there are additional slots in the main type object, with a flag bit being set to indicate that the slots are present and should be checked by the interpreter. (The flag bit does not indicate that the slot values are non-NULL. The flag may be set to indicate the presence of a slot, but a slot may still be unfilled.)

```
PyNumberMethods    *tp_as_number;  
PySequenceMethods  *tp_as_sequence;  
PyMappingMethods   *tp_as_mapping;
```

If you wish your object to be able to act like a number, a sequence, or a mapping object, then you place the address of a structure that implements the C type [PyNumberMethods](#), [PySequenceMethods](#), or [PyMappingMethods](#), respectively. It is up to you to fill in this structure with appropriate values. You can find examples of the use of each of these in the `Objects` directory of the Python source distribution.

```
hashfunc tp_hash;
```

This function, if you choose to provide it, should return a hash number for an instance of your data type. Here is a simple example:

```
static Py_hash_t  
newdatatype_hash(newdatatypeobject *obj)  
{  
    Py_hash_t result;  
    result = obj->some_size + 32767 * obj->some_number;  
    if (result == -1)  
        result = -2;  
    return result;  
}
```

**Py\_hash\_t** is a signed integer type with a platform-varying width.

Returning `-1` from `tp_hash` indicates an error, which is why you should be careful to avoid returning it when hash computation is successful, as seen above.

```
ternaryfunc tp_call;
```

This function is called when an instance of your data type is “called”, for example, if `obj1` is an instance of your data type and the Python script contains `obj1('hello')`, the `tp_call` handler is invoked.

This function takes three arguments:

1. *self* is the instance of the data type which is the subject of the call. If the call is `obj1('hello')`, then *self* is `obj1`.
2. *args* is a tuple containing the arguments to the call. You can use `PyArg_ParseTuple()` to extract the arguments.
3. *kwds* is a dictionary of keyword arguments that were passed. If this is non-NULL and you support keyword arguments, use `PyArg_ParseTupleAndKeywords()` to extract the arguments. If you do not want to support keyword arguments and this is non-NULL, raise a `TypeError` with a message saying that keyword arguments are not supported.

Here is a toy `tp_call` implementation:

```
static PyObject *
newdatatype_call(newdatatypeobject *obj, PyObject *args,
{
    PyObject *result;
    const char *arg1;
    const char *arg2;
    const char *arg3;

    if (!PyArg_ParseTuple(args, "sss:call", &arg1, &arg2,
        return NULL;
    }
    result = PyUnicode_FromFormat(
        "Returning -- value: [%d] arg1: [%s] arg2: [%s]
        obj->obj_UnderlyingDatatypePtr->size,
```

```

        arg1, arg2, arg3);
    return result;
}

/* Iterators */
getiterfunc tp_iter;
iternextfunc tp_iternext;

```

These functions provide support for the iterator protocol. Both handlers take exactly one parameter, the instance for which they are being called, and return a new reference. In the case of an error, they should set an exception and return `NULL`. `tp_iter` corresponds to the Python `__iter__()` method, while `tp_iternext` corresponds to the Python `__next__()` method.

Any `iterable` object must implement the `tp_iter` handler, which must return an `iterator` object. Here the same guidelines apply as for Python classes:

- For collections (such as lists and tuples) which can support multiple independent iterators, a new iterator should be created and returned by each call to `tp_iter`.
- Objects which can only be iterated over once (usually due to side effects of iteration, such as file objects) can implement `tp_iter` by returning a new reference to themselves – and should also therefore implement the `tp_iternext` handler.

Any `iterator` object should implement both `tp_iter` and `tp_iternext`. An iterator's `tp_iter` handler should return a new reference to the iterator. Its `tp_iternext` handler should return a new reference to the next object in the iteration, if there is one. If the iteration has reached the end, `tp_iternext` may return `NULL` without setting an exception, or it may set `StopIteration` in addition to returning `NULL`; avoiding the exception can yield slightly better performance. If an actual error occurs, `tp_iternext` should always set an exception and return `NULL`.

## 3.6. Weak Reference Support

One of the goals of Python's weak reference implementation is to

allow any type to participate in the weak reference mechanism without incurring the overhead on performance-critical objects (such as numbers).

## See also

Documentation for the [weakref](#) module.

For an object to be weakly referencable, the extension type must set the `Py_TPFLAGS_MANAGED_WEAKREF` bit of the `tp_flags` field. The legacy `tp_weaklistoffset` field should be left as zero.

Concretely, here is how the statically declared type object would look:

```
static PyObject TrivialType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    /* ... other members omitted for brevity ... */
    .tp_flags = Py_TPFLAGS_MANAGED_WEAKREF | ...,
};
```

The only further addition is that `tp_dealloc` needs to clear any weak references (by calling [PyObject\\_ClearWeakRefs\(\)](#)):

```
static void
Trivial_dealloc(TrivialObject *self)
{
    /* Clear weakrefs first before calling any destructors */
    PyObject_ClearWeakRefs((PyObject *) self);
    /* ... remainder of destruction code omitted for brevity ... */
    Py_TYPE(self)->tp_free((PyObject *) self);
}
```

## 3.7. More Suggestions

In order to learn how to implement any specific method for your new data type, get the [CPython](#) source code. Go to the `Objects` directory, then search the C source files for `tp_` plus the function you want (for example, `tp_richcompare`). You will find

examples of the function you want to implement.

When you need to verify that an object is a concrete instance of the type you are implementing, use the `PyObject_TypeCheck()` function. A sample of its use might be something like the following:

```
if (!PyObject_TypeCheck(some_object, &MyType)) {
    PyErr_SetString(PyExc_TypeError, "arg #1 not a mythi
    return NULL;
}
```

## 4. Building C and C++ Extensions

A C extension for CPython is a shared library (e.g. a `.so` file on Linux, `.pyd` on Windows), which exports an *initialization function*.

To be importable, the shared library must be available on `PYTHONPATH`, and must be named after the module name, with an appropriate extension. When using `setuptools`, the correct filename is generated automatically.

The initialization function has the signature:

```
PyObject *PyInit_modulename(void)
```

It returns either a fully initialized module, or a `PyModuleDef` instance. See [Initializing C modules](#) for details.

For modules with ASCII-only names, the function must be named `PyInit_<modulename>`, with `<modulename>` replaced by the name of the module. When using [Multi-phase initialization](#), non-ASCII module names are allowed. In this case, the initialization function name is `PyInitU_<modulename>`, with `<modulename>` encoded using Python's *punycode* encoding with hyphens replaced by underscores. In Python:

```
def initfunc_name(name):
    try:
        suffix = b'_' + name.encode('ascii')
    except UnicodeEncodeError:
        suffix = b'U_' + name.encode('punycode').replace(
            '-', '_')
    return b'PyInit' + suffix
```

It is possible to export multiple modules from a single shared library by defining multiple initialization functions. However,

importing them requires using symbolic links or a custom importer, because by default only the function corresponding to the filename is found. See the “*Multiple modules in one library*” section in [PEP 489](https://peps.python.org/pep-0489/) [https://peps.python.org/pep-0489/] for details.

## 4.1. Building C and C++ Extensions with setuptools

Python 3.12 and newer no longer come with distutils. Please refer to the `setuptools` documentation at <https://setuptools.readthedocs.io/en/latest/setuptools.html> to learn more about how build and distribute C/C++ extensions with setuptools.

## 5. Building C and C++ Extensions on Windows

This chapter briefly explains how to create a Windows extension module for Python using Microsoft Visual C++, and follows with more detailed background information on how it works. The explanatory material is useful for both the Windows programmer learning to build Python extensions and the Unix programmer interested in producing software which can be successfully built on both Unix and Windows.

Module authors are encouraged to use the `distutils` approach for building extension modules, instead of the one described in this section. You will still need the C compiler that was used to build Python; typically Microsoft Visual C++.

### Note

This chapter mentions a number of filenames that include an encoded Python version number. These filenames are represented with the version number shown as `XY`; in practice, 'X' will be the major version number and 'Y' will be the minor version number of the Python release you're working with. For example, if you are using Python 2.2.1, `XY` will actually be `22`.

### 5.1. A Cookbook Approach

There are two approaches to building extension modules on Windows, just as there are on Unix: use the `setuptools` package to control the build process, or do things manually. The `setuptools` approach works well for most extensions; documentation on using `setuptools` to build and package extension modules is available in [Building C and C++ Extensions with setuptools](#). If you find you

really need to do things manually, it may be instructive to study the project file for the [winsound](https://github.com/python/cpython/tree/3.12/PCbuild/winsound.vcxproj) [https://github.com/python/cpython/tree/3.12/PCbuild/winsound.vcxproj] standard library module.

## 5.2. Differences Between Unix and Windows

Unix and Windows use completely different paradigms for run-time loading of code. Before you try to build a module that can be dynamically loaded, be aware of how your system works.

In Unix, a shared object (`.so`) file contains code to be used by the program, and also the names of functions and data that it expects to find in the program. When the file is joined to the program, all references to those functions and data in the file's code are changed to point to the actual locations in the program where the functions and data are placed in memory. This is basically a link operation.

In Windows, a dynamic-link library (`.dll`) file has no dangling references. Instead, an access to functions or data goes through a lookup table. So the DLL code does not have to be fixed up at runtime to refer to the program's memory; instead, the code already uses the DLL's lookup table, and the lookup table is modified at runtime to point to the functions and data.

In Unix, there is only one type of library file (`.a`) which contains code from several object files (`.o`). During the link step to create a shared object file (`.so`), the linker may find that it doesn't know where an identifier is defined. The linker will look for it in the object files in the libraries; if it finds it, it will include all the code from that object file.

In Windows, there are two types of library, a static library and an import library (both called `.lib`). A static library is like a Unix `.a` file; it contains code to be included as necessary. An import library is basically used only to reassure the linker that a certain identifier is legal, and will be present in the program when the DLL is loaded. So the linker uses the information from the import library to build the lookup table for using identifiers that are not included in the DLL. When an application or a DLL is linked, an import library may

be generated, which will need to be used for all future DLLs that depend on the symbols in the application or DLL.

Suppose you are building two dynamic-load modules, B and C, which should share another block of code A. On Unix, you would *not* pass `A.a` to the linker for `B.so` and `C.so`; that would cause it to be included twice, so that B and C would each have their own copy. In Windows, building `A.dll` will also build `A.lib`. You *do* pass `A.lib` to the linker for B and C. `A.lib` does not contain code; it just contains information which will be used at runtime to access A's code.

In Windows, using an import library is sort of like using `import spam`; it gives you access to spam's names, but does not create a separate copy. On Unix, linking with a library is more like `from spam import *`; it does create a separate copy.

## 5.3. Using DLLs in Practice

Windows Python is built in Microsoft Visual C++; using other compilers may or may not work. The rest of this section is MSVC++ specific.

When creating DLLs in Windows, you must pass `pythonXY.lib` to the linker. To build two DLLs, `spam` and `ni` (which uses C functions found in `spam`), you could use these commands:

```
cl /LD /I/python/include spam.c ../libs/pythonXY.lib
cl /LD /I/python/include ni.c spam.lib ../libs/pythonXY.lib
```

The first command created three files: `spam.obj`, `spam.dll` and `spam.lib`. `Spam.dll` does not contain any Python functions (such as `PyArg_ParseTuple()`), but it does know how to find the Python code thanks to `pythonXY.lib`.

The second command created `ni.dll` (and `.obj` and `.lib`), which knows how to find the necessary functions from `spam`, and also from the Python executable.

Not every identifier is exported to the lookup table. If you want any

other modules (including Python) to be able to see your identifiers, you have to say `_declspec(dllexport)`, as in `void _declspec(dllexport) initspam(void)` or `PyObject _declspec(dllexport) *NiGetSpamData(void)`.

Developer Studio will throw in a lot of import libraries that you do not really need, adding about 100K to your executable. To get rid of them, use the Project Settings dialog, Link tab, to specify *ignore default libraries*. Add the correct `msvcrtxx.lib` to the list of libraries.

# 1. Embedding Python in Another Application

The previous chapters discussed how to extend Python, that is, how to extend the functionality of Python by attaching a library of C functions to it. It is also possible to do it the other way around: enrich your C/C++ application by embedding Python in it. Embedding provides your application with the ability to implement some of the functionality of your application in Python rather than C or C++. This can be used for many purposes; one example would be to allow users to tailor the application to their needs by writing some scripts in Python. You can also use it yourself if some of the functionality can be written in Python more easily.

Embedding Python is similar to extending it, but not quite. The difference is that when you extend Python, the main program of the application is still the Python interpreter, while if you embed Python, the main program may have nothing to do with Python — instead, some parts of the application occasionally call the Python interpreter to run some Python code.

So if you are embedding Python, you are providing your own main program. One of the things this main program has to do is initialize the Python interpreter. At the very least, you have to call the function `Py_Initialize()`. There are optional calls to pass command line arguments to Python. Then later you can call the interpreter from any part of the application.

There are several different ways to call the interpreter: you can pass a string containing Python statements to `PyRun_SimpleString()`, or you can pass a stdio file pointer and a file name (for identification in error messages only) to `PyRun_SimpleFile()`. You can also call the lower-level operations described in the previous chapters to construct and use Python objects.

See also

### Python/C API Reference Manual

The details of Python's C interface are given in this manual. A great deal of necessary information can be found here.

## 1.1. Very High Level Embedding

The simplest form of embedding Python is the use of the very high level interface. This interface is intended to execute a Python script without needing to interact with the application directly. This can for example be used to perform some operation on a file.

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>

int
main(int argc, char *argv[])
{
    wchar_t *program = Py_DecodeLocale(argv[0], NULL);
    if (program == NULL) {
        fprintf(stderr, "Fatal error: cannot decode argv[0]\n");
        exit(1);
    }
    Py_SetProgramName(program); /* optional but recommended */
    Py_Initialize();
    PyRun_SimpleString("from time import time,ctime\n"
                      "print('Today is', ctime(time()))");
    if (Py_FinalizeEx() < 0) {
        exit(120);
    }
    PyMem_RawFree(program);
    return 0;
}
```

The `Py_SetProgramName()` function should be called before `Py_Initialize()` to inform the interpreter about paths to Python

run-time libraries. Next, the Python interpreter is initialized with `Py_Initialize()`, followed by the execution of a hard-coded Python script that prints the date and time. Afterwards, the `Py_FinalizeEx()` call shuts the interpreter down, followed by the end of the program. In a real program, you may want to get the Python script from another source, perhaps a text-editor routine, a file, or a database. Getting the Python code from a file can better be done by using the `PyRun_SimpleFile()` function, which saves you the trouble of allocating memory space and loading the file contents.

## 1.2. Beyond Very High Level Embedding: An overview

The high level interface gives you the ability to execute arbitrary pieces of Python code from your application, but exchanging data values is quite cumbersome to say the least. If you want that, you should use lower level calls. At the cost of having to write more C code, you can achieve almost anything.

It should be noted that extending Python and embedding Python is quite the same activity, despite the different intent. Most topics discussed in the previous chapters are still valid. To show this, consider what the extension code from Python to C really does:

1. Convert data values from Python to C,
2. Perform a function call to a C routine using the converted values, and
3. Convert the data values from the call from C to Python.

When embedding Python, the interface code does:

1. Convert data values from C to Python,
2. Perform a function call to a Python interface routine using the converted values, and
3. Convert the data values from the call from Python to C.

As you can see, the data conversion steps are simply swapped to accommodate the different direction of the cross-language transfer. The only difference is the routine that you call between both data

conversions. When extending, you call a C routine, when embedding, you call a Python routine.

This chapter will not discuss how to convert data from Python to C and vice versa. Also, proper use of references and dealing with errors is assumed to be understood. Since these aspects do not differ from extending the interpreter, you can refer to earlier chapters for the required information.

## 1.3. Pure Embedding

The first program aims to execute a function in a Python script. Like in the section about the very high level interface, the Python interpreter does not directly interact with the application (but that will change in the next section).

The code to run a function defined in a Python script is:

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>

int
main(int argc, char *argv[])
{
    PyObject *pName, *pModule, *pFunc;
    PyObject *pArgs, *pValue;
    int i;

    if (argc < 3) {
        fprintf(stderr, "Usage: call pythonfile funcname\n");
        return 1;
    }

    Py_Initialize();
    pName = PyUnicode_DecodeFSDefault(argv[1]);
    /* Error checking of pName left out */

    pModule = PyImport_Import(pName);
    Py_DECREF(pName);
```

```

if (pModule != NULL) {
    pFunc = PyObject_GetAttrString(pModule, argv[2])
    /* pFunc is a new reference */

    if (pFunc && PyCallable_Check(pFunc)) {
        pArgs = PyTuple_New(argc - 3);
        for (i = 0; i < argc - 3; ++i) {
            pValue = PyLong_FromLong(atoi(argv[i + 3]));
            if (!pValue) {
                Py_DECREF(pArgs);
                Py_DECREF(pModule);
                fprintf(stderr, "Cannot convert argument\n");
                return 1;
            }
            /* pValue reference stolen here: */
            PyTuple_SetItem(pArgs, i, pValue);
        }
        pValue = PyObject_CallObject(pFunc, pArgs);
        Py_DECREF(pArgs);
        if (pValue != NULL) {
            printf("Result of call: %ld\n", PyLong_AsLong(pValue));
            Py_DECREF(pValue);
        }
        else {
            Py_DECREF(pFunc);
            Py_DECREF(pModule);
            PyErr_Print();
            fprintf(stderr, "Call failed\n");
            return 1;
        }
    }
    else {
        if (PyErr_Occurred())
            PyErr_Print();
        fprintf(stderr, "Cannot find function \"%s\"\n", argv[2]);
    }
    Py_XDECREF(pFunc);
}

```

```

        Py_DECREF(pModule);
    }
    else {
        PyErr_Print();
        fprintf(stderr, "Failed to load \"%s\"\n", argv[1]);
        return 1;
    }
    if (Py_FinalizeEx() < 0) {
        return 120;
    }
    return 0;
}

```

This code loads a Python script using `argv[1]`, and calls the function named in `argv[2]`. Its integer arguments are the other values of the `argv` array. If you [compile and link](#) this program (let's call the finished executable **call**), and use it to execute a Python script, such as:

```

def multiply(a,b):
    print("Will compute", a, "times", b)
    c = 0
    for i in range(0, a):
        c = c + b
    return c

```

then the result should be:

```

$ call multiply multiply 3 2
Will compute 3 times 2
Result of call: 6

```

Although the program is quite large for its functionality, most of the code is for data conversion between Python and C, and for error reporting. The interesting part with respect to embedding Python starts with

```

Py_Initialize();
pName = PyUnicode_DecodeFSDefault(argv[1]);
/* Error checking of pName left out */

```

```
pModule = PyImport_Import(pName);
```

After initializing the interpreter, the script is loaded using `PyImport_Import()`. This routine needs a Python string as its argument, which is constructed using the `PyUnicode_FromString()` data conversion routine.

```
pFunc = PyObject_GetAttrString(pModule, argv[2]);  
/* pFunc is a new reference */
```

```
if (pFunc && PyCallable_Check(pFunc)) {  
    ...  
}  
Py_XDECREF(pFunc);
```

Once the script is loaded, the name we're looking for is retrieved using `PyObject_GetAttrString()`. If the name exists, and the object returned is callable, you can safely assume that it is a function. The program then proceeds by constructing a tuple of arguments as normal. The call to the Python function is then made with:

```
pValue = PyObject_CallObject(pFunc, pArgs);
```

Upon return of the function, `pValue` is either `NULL` or it contains a reference to the return value of the function. Be sure to release the reference after examining the value.

## 1.4. Extending Embedded Python

Until now, the embedded Python interpreter had no access to functionality from the application itself. The Python API allows this by extending the embedded interpreter. That is, the embedded interpreter gets extended with routines provided by the application. While it sounds complex, it is not so bad. Simply forget for a while that the application starts the Python interpreter. Instead, consider the application to be a set of subroutines, and write some glue code that gives Python access to those routines, just like you would write a normal Python extension. For example:

```

static int numargs=0;

/* Return the number of arguments of the application command line
static PyObject*
emb_numargs(PyObject *self, PyObject *args)
{
    if(!PyArg_ParseTuple(args, ":numargs"))
        return NULL;
    return PyLong_FromLong(numargs);
}

static PyMethodDef EmbMethods[] = {
    {"numargs", emb_numargs, METH_VARARGS,
     "Return the number of arguments received by the program"},
    {NULL, NULL, 0, NULL}
};

static PyModuleDef EmbModule = {
    PyModuleDef_HEAD_INIT, "emb", NULL, -1, EmbMethods,
    NULL, NULL, NULL, NULL
};

static PyObject*
PyInit_emb(void)
{
    return PyModule_Create(&EmbModule);
}

```

Insert the above code just above the **main()** function. Also, insert the following two statements before the call to **Py\_Initialize()**:

```

numargs = argc;
PyImport_AppendInittab("emb", &PyInit_emb);

```

These two lines initialize the `numargs` variable, and make the **emb.numargs()** function accessible to the embedded Python interpreter. With these extensions, the Python script can do things like

```
import emb
print("Number of arguments", emb.numargs())
```

In a real application, the methods will expose an API of the application to Python.

## 1.5. Embedding Python in C++

It is also possible to embed Python in a C++ program; precisely how this is done will depend on the details of the C++ system used; in general you will need to write the main program in C++, and use the C++ compiler to compile and link your program. There is no need to recompile Python itself using C++.

## 1.6. Compiling and Linking under Unix-like systems

It is not necessarily trivial to find the right flags to pass to your compiler (and linker) in order to embed the Python interpreter into your application, particularly because Python needs to load library modules implemented as C dynamic extensions (.so files) linked against it.

To find out the required compiler and linker flags, you can execute the `pythonX.Y-config` script which is generated as part of the installation process (a `python3-config` script may also be available). This script has several options, of which the following will be directly useful to you:

- `pythonX.Y-config --cflags` will give you the recommended flags when compiling:

```
$ /opt/bin/python3.11-config --cflags
-I/opt/include/python3.11 -I/opt/include/python3.11
```

- `pythonX.Y-config --ldflags --embed` will give you the recommended flags when linking:

```
$ /opt/bin/python3.11-config --ldflags --embed
```

```
-L/opt/lib/python3.11/config-3.11-x86_64-linux-gnu
```

## Note

To avoid confusion between several Python installations (and especially between the system Python and your own compiled Python), it is recommended that you use the absolute path to `pythonX.Y-config`, as in the above example.

If this procedure doesn't work for you (it is not guaranteed to work for all Unix-like platforms; however, we welcome [bug reports](#)) you will have to read your system's documentation about dynamic linking and/or examine Python's `Makefile` (use `sysconfig.get_makefile_filename()` to find its location) and compilation options. In this case, the `sysconfig` module is a useful tool to programmatically extract the configuration values that you will want to combine together. For example:

```
>>> import sysconfig
>>> sysconfig.get_config_var('LIBS')
'-lpthread -ldl -lutil'
>>> sysconfig.get_config_var('LINKFORSHARED')
'-Xlinker -export-dynamic'
```

# Python/C API Reference Manual

This manual documents the API used by C and C++ programmers who want to write extension modules or embed Python. It is a companion to [Extending and Embedding the Python Interpreter](#), which describes the general principles of extension writing but does not document the API functions in detail.

# Introduction

The Application Programmer's Interface to Python gives C and C++ programmers access to the Python interpreter at a variety of levels. The API is equally usable from C++, but for brevity it is generally referred to as the Python/C API. There are two fundamentally different reasons for using the Python/C API. The first reason is to write *extension modules* for specific purposes; these are C modules that extend the Python interpreter. This is probably the most common use. The second reason is to use Python as a component in a larger application; this technique is generally referred to as *embedding* Python in an application.

Writing an extension module is a relatively well-understood process, where a “cookbook” approach works well. There are several tools that automate the process to some extent. While people have embedded Python in other applications since its early existence, the process of embedding Python is less straightforward than writing an extension.

Many API functions are useful independent of whether you're embedding or extending Python; moreover, most applications that embed Python will need to provide a custom extension as well, so it's probably a good idea to become familiar with writing an extension before attempting to embed Python in a real application.

## Coding standards

If you're writing C code for inclusion in CPython, you **must** follow the guidelines and standards defined in [PEP 7](https://peps.python.org/pep-0007/) [https://peps.python.org/pep-0007/]. These guidelines apply regardless of the version of Python you are contributing to. Following these conventions is not necessary for your own third party extension modules, unless you eventually expect to contribute them to Python.

# Include Files

All function, type and macro definitions needed to use the Python/C API are included in your code by the following line:

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>
```

This implies inclusion of the following standard headers:

`<stdio.h>`, `<string.h>`, `<errno.h>`, `<limits.h>`,  
`<assert.h>` and `<stdlib.h>` (if available).

## Note

Since Python may define some pre-processor definitions which affect the standard headers on some systems, you *must* include `Python.h` before any standard headers are included.

It is recommended to always define `PY_SSIZE_T_CLEAN` before including `Python.h`. See [Parsing arguments and building values](#) for a description of this macro.

All user visible names defined by `Python.h` (except those defined by the included standard headers) have one of the prefixes `Py` or `_Py`. Names beginning with `_Py` are for internal use by the Python implementation and should not be used by extension writers. Structure member names do not have a reserved prefix.

## Note

User code should never define names that begin with `Py` or `_Py`. This confuses the reader, and jeopardizes the portability of the user code to future Python versions, which may define additional names beginning with one of these prefixes.

The header files are typically installed with Python. On Unix, these are located in the directories `prefix/include/pythonversion/` and `exec_prefix/include/pythonversion/`, where `prefix` and `exec_prefix` are defined

by the corresponding parameters to Python's **configure** script and *version* is `'%d.%d' % sys.version_info[:2]`. On Windows, the headers are installed in `prefix/include`, where `prefix` is the installation directory specified to the installer.

To include the headers, place both directories (if different) on your compiler's search path for includes. Do *not* place the parent directories on the search path and then use `#include <pythonX.Y/Python.h>`; this will break on multi-platform builds since the platform independent headers under `prefix` include the platform specific headers from `exec_prefix`.

C++ users should note that although the API is defined entirely using C, the header files properly declare the entry points to be `extern "C"`. As a result, there is no need to do anything special to use the API from C++.

## Useful macros

Several useful macros are defined in the Python header files. Many are defined closer to where they are useful (e.g. `Py_RETURN_NONE`). Others of a more general utility are defined here. This is not necessarily a complete listing.

### PyMODINIT\_FUNC

Declare an extension module `PyInit` initialization function. The function return type is `PyObject*`. The macro declares any special linkage declarations required by the platform, and for C++ declares the function as `extern "C"`.

The initialization function must be named `PyInit_name`, where *name* is the name of the module, and should be the only non-static item defined in the module file. Example:

```
static struct PyModuleDef spam_module = {
    PyModuleDef_HEAD_INIT,
    .m_name = "spam",
    ...
};
```

```
PyMODINIT_FUNC
PyInit_spam(void)
{
    return PyModule_Create(&spam_module);
}
```

## Py\_ABS(x)

Return the absolute value of `x`.

*New in version 3.3.*

## Py\_ALWAYS\_INLINE

Ask the compiler to always inline a static inline function. The compiler can ignore it and decides to not inline the function.

It can be used to inline performance critical static inline functions when building Python in debug mode with function inlining disabled. For example, MSC disables function inlining when building in debug mode.

Marking blindly a static inline function with `Py_ALWAYS_INLINE` can result in worse performances (due to increased code size for example). The compiler is usually smarter than the developer for the cost/benefit analysis.

If Python is [built in debug mode](#) (if the `Py_DEBUG` macro is defined), the `Py_ALWAYS_INLINE` macro does nothing.

It must be specified before the function return type. Usage:

```
static inline Py_ALWAYS_INLINE int random(void) { r
```

*New in version 3.11.*

## Py\_CHARMASK(c)

Argument must be a character or an integer in the range `[-128, 127]` or `[0, 255]`. This macro returns `c` cast to an unsigned char.

## Py\_DEPRECATED(version)

Use this for deprecated declarations. The macro must be placed before the symbol name.

Example:

```
Py_DEPRECATED(3.8) PyAPI_FUNC(int) Py_OldFunction(v
```

*Changed in version 3.8:* MSVC support was added.

## Py\_GETENV(s)

Like `getenv(s)`, but returns `NULL` if `-E` was passed on the command line (see [PyConfig.use\\_environment](#)).

## Py\_MAX(x, y)

Return the maximum value between `x` and `y`.

*New in version 3.3.*

## Py\_MEMBER\_SIZE(type, member)

Return the size of a structure (`type`) member in bytes.

*New in version 3.6.*

## Py\_MIN(x, y)

Return the minimum value between `x` and `y`.

*New in version 3.3.*

## Py\_NO\_INLINE

Disable inlining on a function. For example, it reduces the C stack consumption: useful on LTO + PGO builds which heavily inline code (see [bpo-33720](https://bugs.python.org/issue?@action=redirect&bpo=33720) [https://bugs.python.org/issue?@action=redirect&bpo=33720]).

Usage:

```
Py_NO_INLINE static int random(void) { return 4; }
```

*New in version 3.11.*

## Py\_STRINGIFY(x)

Convert `x` to a C string. E.g. `Py_STRINGIFY(123)` returns `"123"`.

*New in version 3.4.*

## Py\_UNREACHABLE()

Use this when you have a code path that cannot be reached by design. For example, in the `default:` clause in a `switch` statement for which all possible values are covered in `case` statements. Use this in places where you might be tempted to put an `assert(0)` or `abort()` call.

In release mode, the macro helps the compiler to optimize the code, and avoids a warning about unreachable code. For example, the macro is implemented with `__builtin_unreachable()` on GCC in release mode.

A use for `Py_UNREACHABLE()` is following a call a function that never returns but that is not declared `_Py_NO_RETURN`.

If a code path is very unlikely code but can be reached under exceptional case, this macro must not be used. For example, under low memory condition or if a system call returns a value out of the expected range. In this case, it's better to report the error to the caller. If the error cannot be reported to caller, `Py_FatalError()` can be used.

*New in version 3.7.*

## Py\_UNUSED(arg)

Use this for unused arguments in a function definition to silence compiler warnings. Example: `int func(int a, int Py_UNUSED(b)) { return a; }`.

*New in version 3.4.*

## PyDoc\_STRVAR(name, str)

Creates a variable with name `name` that can be used in docstrings. If Python is built without docstrings, the value will be empty.

Use [PyDoc\\_STRVAR](#) for docstrings to support building Python without docstrings, as specified in [PEP 7](#) [<https://peps.python.org/pep-0007/>].

Example:

```
PyDoc_STRVAR(pop_doc, "Remove and return the rightmost element")

static PyMethodDef deque_methods[] = {
    // ...
    {"pop", (PyCFunction)deque_pop, METH_NOARGS, pop_doc},
    // ...
}
```

## PyDoc\_STR(str)

Creates a docstring for the given input string or an empty string if docstrings are disabled.

Use [PyDoc\\_STR](#) in specifying docstrings to support building Python without docstrings, as specified in [PEP 7](#) [<https://peps.python.org/pep-0007/>].

Example:

```
static PyMethodDef sqlite3_row_methods[] = {
    {"keys", (PyCFunction)sqlite3_row_keys, METH_NOARGS,
     PyDoc_STR("Returns the keys of the row.")},
    {NULL, NULL}
};
```

# Objects, Types and Reference Counts

Most Python/C API functions have one or more arguments as well as a return value of type [PyObject\\*](#). This type is a pointer to an

opaque data type representing an arbitrary Python object. Since all Python object types are treated the same way by the Python language in most situations (e.g., assignments, scope rules, and argument passing), it is only fitting that they should be represented by a single C type. Almost all Python objects live on the heap: you never declare an automatic or static variable of type `PyObject`, only pointer variables of type `PyObject*` can be declared. The sole exception are the type objects; since these must never be deallocated, they are typically static `PyTypeObject` objects.

All Python objects (even Python integers) have a *type* and a *reference count*. An object's type determines what kind of object it is (e.g., an integer, a list, or a user-defined function; there are many more as explained in [The standard type hierarchy](#)). For each of the well-known types there is a macro to check whether an object is of that type; for instance, `PyList_Check(a)` is true if (and only if) the object pointed to by `a` is a Python list.

## Reference Counts

The reference count is important because today's computers have a finite (and often severely limited) memory size; it counts how many different places there are that have a [strong reference](#) to an object. Such a place could be another object, or a global (or static) C variable, or a local variable in some C function. When the last [strong reference](#) to an object is released (i.e. its reference count becomes zero), the object is deallocated. If it contains references to other objects, those references are released. Those other objects may be deallocated in turn, if there are no more references to them, and so on. (There's an obvious problem with objects that reference each other here; for now, the solution is "don't do that.")

Reference counts are always manipulated explicitly. The normal way is to use the macro `Py_INCREF()` to take a new reference to an object (i.e. increment its reference count by one), and `Py_DECREF()` to release that reference (i.e. decrement the reference count by one). The `Py_DECREF()` macro is considerably more complex than the `incr` one, since it must check whether the reference count becomes zero and then cause the object's deallocator to be called. The deallocator is a function pointer

contained in the object's type structure. The type-specific deallocator takes care of releasing references for other objects contained in the object if this is a compound object type, such as a list, as well as performing any additional finalization that's needed. There's no chance that the reference count can overflow; at least as many bits are used to hold the reference count as there are distinct memory locations in virtual memory (assuming `sizeof(Py_ssize_t) >= sizeof(void*)`). Thus, the reference count increment is a simple operation.

It is not necessary to hold a [strong reference](#) (i.e. increment the reference count) for every local variable that contains a pointer to an object. In theory, the object's reference count goes up by one when the variable is made to point to it and it goes down by one when the variable goes out of scope. However, these two cancel each other out, so at the end the reference count hasn't changed. The only real reason to use the reference count is to prevent the object from being deallocated as long as our variable is pointing to it. If we know that there is at least one other reference to the object that lives at least as long as our variable, there is no need to take a new [strong reference](#) (i.e. increment the reference count) temporarily. An important situation where this arises is in objects that are passed as arguments to C functions in an extension module that are called from Python; the call mechanism guarantees to hold a reference to every argument for the duration of the call.

However, a common pitfall is to extract an object from a list and hold on to it for a while without taking a new reference. Some other operation might conceivably remove the object from the list, releasing that reference, and possibly deallocating it. The real danger is that innocent-looking operations may invoke arbitrary Python code which could do this; there is a code path which allows control to flow back to the user from a [Py\\_DECREF\(\)](#), so almost any operation is potentially dangerous.

A safe approach is to always use the generic operations (functions whose name begins with `PyObject_`, `PyNumber_`, `PySequence_` or `PyMapping_`). These operations always create a new [strong reference](#) (i.e. increment the reference count) of the object they return. This leaves the caller with the responsibility to

call `Py_DECREF()` when they are done with the result; this soon becomes second nature.

## Reference Count Details

The reference count behavior of functions in the Python/C API is best explained in terms of *ownership of references*. Ownership pertains to references, never to objects (objects are not owned: they are always shared). “Owning a reference” means being responsible for calling `Py_DECREF()` on it when the reference is no longer needed. Ownership can also be transferred, meaning that the code that receives ownership of the reference then becomes responsible for eventually releasing it by calling `Py_DECREF()` or `Py_XDECREF()` when it’s no longer needed—or passing on this responsibility (usually to its caller). When a function passes ownership of a reference on to its caller, the caller is said to receive a *new* reference. When no ownership is transferred, the caller is said to *borrow* the reference. Nothing needs to be done for a *borrowed reference*.

Conversely, when a calling function passes in a reference to an object, there are two possibilities: the function *steals* a reference to the object, or it does not. *Stealing a reference* means that when you pass a reference to a function, that function assumes that it now owns that reference, and you are not responsible for it any longer.

Few functions steal references; the two notable exceptions are `PyList_SetItem()` and `PyTuple_SetItem()`, which steal a reference to the item (but not to the tuple or list into which the item is put!). These functions were designed to steal a reference because of a common idiom for populating a tuple or list with newly created objects; for example, the code to create the tuple `(1, 2, "three")` could look like this (forgetting about error handling for the moment; a better way to code this is shown below):

```
PyObject *t;  
  
t = PyTuple_New(3);  
PyTuple_SetItem(t, 0, PyLong_FromLong(1L));
```

```
PyTuple_SetItem(t, 1, PyLong_FromLong(2L));
PyTuple_SetItem(t, 2, PyUnicode_FromString("three"));
```

Here, `PyLong_FromLong()` returns a new reference which is immediately stolen by `PyTuple_SetItem()`. When you want to keep using an object although the reference to it will be stolen, use `Py_INCREF()` to grab another reference before calling the reference-stealing function.

Incidentally, `PyTuple_SetItem()` is the *only* way to set tuple items; `PySequence_SetItem()` and `PyObject_SetItem()` refuse to do this since tuples are an immutable data type. You should only use `PyTuple_SetItem()` for tuples that you are creating yourself.

Equivalent code for populating a list can be written using `PyList_New()` and `PyList_SetItem()`.

However, in practice, you will rarely use these ways of creating and populating a tuple or list. There's a generic function, `Py_BuildValue()`, that can create most common objects from C values, directed by a *format string*. For example, the above two blocks of code could be replaced by the following (which also takes care of the error checking):

```
PyObject *tuple, *list;

tuple = Py_BuildValue("(iis)", 1, 2, "three");
list = Py_BuildValue("[iis]", 1, 2, "three");
```

It is much more common to use `PyObject_SetItem()` and friends with items whose references you are only borrowing, like arguments that were passed in to the function you are writing. In that case, their behaviour regarding references is much saner, since you don't have to take a new reference just so you can give that reference away ("have it be stolen"). For example, this function sets all items of a list (actually, any mutable sequence) to a given item:

```
int
set_all(PyObject *target, PyObject *item)
{
```

```

Py_ssize_t i, n;

n = PyObject_Length(target);
if (n < 0)
    return -1;
for (i = 0; i < n; i++) {
    PyObject *index = PyLong_FromSsize_t(i);
    if (!index)
        return -1;
    if (PyObject_SetItem(target, index, item) < 0) {
        Py_DECREF(index);
        return -1;
    }
    Py_DECREF(index);
}
return 0;
}

```

The situation is slightly different for function return values. While passing a reference to most functions does not change your ownership responsibilities for that reference, many functions that return a reference to an object give you ownership of the reference. The reason is simple: in many cases, the returned object is created on the fly, and the reference you get is the only reference to the object. Therefore, the generic functions that return object references, like `PyObject_GetItem()` and `PySequence_GetItem()`, always return a new reference (the caller becomes the owner of the reference).

It is important to realize that whether you own a reference returned by a function depends on which function you call only — *the plumage* (the type of the object passed as an argument to the function) *doesn't enter into it!* Thus, if you extract an item from a list using `PyList_GetItem()`, you don't own the reference — but if you obtain the same item from the same list using `PySequence_GetItem()` (which happens to take exactly the same arguments), you do own a reference to the returned object.

Here is an example of how you could write a function that computes the sum of the items in a list of integers; once using

`PyList_GetItem()`, and once using `PySequence_GetItem()`.

```
long
sum_list(PyObject *list)
{
    Py_ssize_t i, n;
    long total = 0, value;
    PyObject *item;

    n = PyList_Size(list);
    if (n < 0)
        return -1; /* Not a list */
    for (i = 0; i < n; i++) {
        item = PyList_GetItem(list, i); /* Can't fail */
        if (!PyLong_Check(item)) continue; /* Skip non-integers */
        value = PyLong_AsLong(item);
        if (value == -1 && PyErr_Occurred())
            /* Integer too big to fit in a C long, bail out */
            return -1;
        total += value;
    }
    return total;
}

long
sum_sequence(PyObject *sequence)
{
    Py_ssize_t i, n;
    long total = 0, value;
    PyObject *item;
    n = PySequence_Length(sequence);
    if (n < 0)
        return -1; /* Has no length */
    for (i = 0; i < n; i++) {
        item = PySequence_GetItem(sequence, i);
        if (item == NULL)
            return -1; /* Not a sequence, or other failure */
        if (!PyLong_Check(item)) {
            /* Not a long, bail out */
            return -1;
        }
        value = PyLong_AsLong(item);
        total += value;
    }
    return total;
}
```

```

        Py_DECREF(item);
        if (value == -1 && PyErr_Occurred())
            /* Integer too big to fit in a C long, b
            return -1;
        total += value;
    }
    else {
        Py_DECREF(item); /* Discard reference owners
    }
}
return total;
}

```

## Types

There are few other data types that play a significant role in the Python/C API; most are simple C types such as `int`, `long`, `double` and `char*`. A few structure types are used to describe static tables used to list the functions exported by a module or the data attributes of a new object type, and another is used to describe the value of a complex number. These will be discussed together with the functions that use them.

type `Py_ssize_t`

*Part of the [Stable ABI](#).*

A signed integral type such that `sizeof(Py_ssize_t) == sizeof(size_t)`. C99 doesn't define such a thing directly (`size_t` is an unsigned integral type). See [PEP 353](#) [<https://peps.python.org/pep-0353/>] for details. `PY_SSIZE_T_MAX` is the largest positive value of type `Py_ssize_t`.

## Exceptions

The Python programmer only needs to deal with exceptions if specific error handling is required; unhandled exceptions are automatically propagated to the caller, then to the caller's caller, and so on, until they reach the top-level interpreter, where they are reported to the user accompanied by a stack traceback.

For C programmers, however, error checking always has to be explicit. All functions in the Python/C API can raise exceptions, unless an explicit claim is made otherwise in a function's documentation. In general, when a function encounters an error, it sets an exception, discards any object references that it owns, and returns an error indicator. If not documented otherwise, this indicator is either `NULL` or `-1`, depending on the function's return type. A few functions return a Boolean true/false result, with false indicating an error. Very few functions return no explicit error indicator or have an ambiguous return value, and require explicit testing for errors with `PyErr_Occurred()`. These exceptions are always explicitly documented.

Exception state is maintained in per-thread storage (this is equivalent to using global storage in an unthreaded application). A thread can be in one of two states: an exception has occurred, or not. The function `PyErr_Occurred()` can be used to check for this: it returns a borrowed reference to the exception type object when an exception has occurred, and `NULL` otherwise. There are a number of functions to set the exception state:

`PyErr_SetString()` is the most common (though not the most general) function to set the exception state, and `PyErr_Clear()` clears the exception state.

The full exception state consists of three objects (all of which can be `NULL`): the exception type, the corresponding exception value, and the traceback. These have the same meanings as the Python result of `sys.exc_info()`; however, they are not the same: the Python objects represent the last exception being handled by a Python `try ... except` statement, while the C level exception state only exists while an exception is being passed on between C functions until it reaches the Python bytecode interpreter's main loop, which takes care of transferring it to `sys.exc_info()` and friends.

Note that starting with Python 1.5, the preferred, thread-safe way to access the exception state from Python code is to call the function `sys.exc_info()`, which returns the per-thread exception state for Python code. Also, the semantics of both ways to access the exception state have changed so that a function which catches an exception will save and restore its thread's exception

state so as to preserve the exception state of its caller. This prevents common bugs in exception handling code caused by an innocent-looking function overwriting the exception being handled; it also reduces the often unwanted lifetime extension for objects that are referenced by the stack frames in the traceback.

As a general principle, a function that calls another function to perform some task should check whether the called function raised an exception, and if so, pass the exception state on to its caller. It should discard any object references that it owns, and return an error indicator, but it should *not* set another exception — that would overwrite the exception that was just raised, and lose important information about the exact cause of the error.

A simple example of detecting exceptions and passing them on is shown in the **sum\_sequence()** example above. It so happens that this example doesn't need to clean up any owned references when it detects an error. The following example function shows some error cleanup. First, to remind you why you like Python, we show the equivalent Python code:

```
def incr_item(dict, key):
    try:
        item = dict[key]
    except KeyError:
        item = 0
    dict[key] = item + 1
```

Here is the corresponding C code, in all its glory:

```
int
incr_item(PyObject *dict, PyObject *key)
{
    /* Objects all initialized to NULL for Py_XDECREF */
    PyObject *item = NULL, *const_one = NULL, *increment;
    int rv = -1; /* Return value initialized to -1 (fail) */

    item = PyObject_GetItem(dict, key);
    if (item == NULL) {
        /* Handle KeyError only: */
```

```

        if (!PyErr_ExceptionMatches(PyExc_KeyError))
            goto error;

        /* Clear the error and use zero: */
        PyErr_Clear();
        item = PyLong_FromLong(0L);
        if (item == NULL)
            goto error;
    }
    const_one = PyLong_FromLong(1L);
    if (const_one == NULL)
        goto error;

    incremented_item = PyNumber_Add(item, const_one);
    if (incremented_item == NULL)
        goto error;

    if (PyObject_SetItem(dict, key, incremented_item) <
        goto error;
    rv = 0; /* Success */
    /* Continue with cleanup code */

error:
    /* Cleanup code, shared by success and failure path

    /* Use Py_XDECREF() to ignore NULL references */
    Py_XDECREF(item);
    Py_XDECREF(const_one);
    Py_XDECREF(incremented_item);

    return rv; /* -1 for error, 0 for success */
}

```

This example represents an endorsed use of the `goto` statement in C! It illustrates the use of [PyErr\\_ExceptionMatches\(\)](#) and [PyErr\\_Clear\(\)](#) to handle specific exceptions, and the use of [Py\\_XDECREF\(\)](#) to dispose of owned references that may be `NULL` (note the 'X' in the name; [Py\\_DECREF\(\)](#) would crash when confronted with a `NULL` reference). It is important that the

variables used to hold owned references are initialized to `NULL` for this to work; likewise, the proposed return value is initialized to `-1` (failure) and only set to success after the final call made is successful.

## Embedding Python

The one important task that only embedders (as opposed to extension writers) of the Python interpreter have to worry about is the initialization, and possibly the finalization, of the Python interpreter. Most functionality of the interpreter can only be used after the interpreter has been initialized.

The basic initialization function is `Py_Initialize()`. This initializes the table of loaded modules, and creates the fundamental modules `builtins`, `__main__`, and `sys`. It also initializes the module search path (`sys.path`).

`Py_Initialize()` does not set the “script argument list” (`sys.argv`). If this variable is needed by Python code that will be executed later, setting `PyConfig.argv` and `PyConfig.parse_argv` must be set: see [Python Initialization Configuration](#).

On most systems (in particular, on Unix and Windows, although the details are slightly different), `Py_Initialize()` calculates the module search path based upon its best guess for the location of the standard Python interpreter executable, assuming that the Python library is found in a fixed location relative to the Python interpreter executable. In particular, it looks for a directory named `lib/pythonX.Y` relative to the parent directory where the executable named `python` is found on the shell command search path (the environment variable `PATH`).

For instance, if the Python executable is found in `/usr/local/bin/python`, it will assume that the libraries are in `/usr/local/lib/pythonX.Y`. (In fact, this particular path is also the “fallback” location, used when no executable file named `python` is found along `PATH`.) The user can override this behavior by setting the environment variable `PYTHONHOME`, or insert additional

directories in front of the standard path by setting `PYTHONPATH`.

The embedding application can steer the search by calling `Py_SetProgramName(file)` *before* calling `Py_Initialize()`. Note that `PYTHONHOME` still overrides this and `PYTHONPATH` is still inserted in front of the standard path. An application that requires total control has to provide its own implementation of `Py_GetPath()`, `Py_GetPrefix()`, `Py_GetExecPrefix()`, and `Py_GetProgramFullPath()` (all defined in `Modules/getpath.c`).

Sometimes, it is desirable to “uninitialize” Python. For instance, the application may want to start over (make another call to `Py_Initialize()`) or the application is simply done with its use of Python and wants to free memory allocated by Python. This can be accomplished by calling `Py_FinalizeEx()`. The function `Py_IsInitialized()` returns true if Python is currently in the initialized state. More information about these functions is given in a later chapter. Notice that `Py_FinalizeEx()` does *not* free all memory allocated by the Python interpreter, e.g. memory allocated by extension modules currently cannot be released.

## Debugging Builds

Python can be built with several macros to enable extra checks of the interpreter and extension modules. These checks tend to add a large amount of overhead to the runtime so they are not enabled by default.

A full list of the various types of debugging builds is in the file `Misc/SpecialBuilds.txt` in the Python source distribution. Builds are available that support tracing of reference counts, debugging the memory allocator, or low-level profiling of the main interpreter loop. Only the most frequently used builds will be described in the remainder of this section.

Compiling the interpreter with the `Py_DEBUG` macro defined produces what is generally meant by a [debug build of Python](#). `Py_DEBUG` is enabled in the Unix build by adding `--with-pydebug` to the `./configure` command. It is also implied by the

presence of the not-Python-specific `_DEBUG` macro. When `Py_DEBUG` is enabled in the Unix build, compiler optimization is disabled.

In addition to the reference count debugging described below, extra checks are performed, see [Python Debug Build](#).

Defining `Py_TRACE_REFS` enables reference tracing (see the [configure --with-trace-refs option](#)). When defined, a circular doubly linked list of active objects is maintained by adding two extra fields to every `PyObject`. Total allocations are tracked as well. Upon exit, all existing references are printed. (In interactive mode this happens after every statement run by the interpreter.)

Please refer to `Misc/SpecialBuilds.txt` in the Python source distribution for more detailed information.

# C API Stability

Unless documented otherwise, Python's C API is covered by the Backwards Compatibility Policy, [PEP 387](https://peps.python.org/pep-0387/) [https://peps.python.org/pep-0387/]. Most changes to it are source-compatible (typically by only adding new API). Changing existing API or removing API is only done after a deprecation period or to fix serious issues.

CPython's Application Binary Interface (ABI) is forward- and backwards-compatible across a minor release (if these are compiled the same way; see [Platform Considerations](#) below). So, code compiled for Python 3.10.0 will work on 3.10.8 and vice versa, but will need to be compiled separately for 3.9.x and 3.10.x.

There are two tiers of C API with different stability expectations:

- [Unstable API](#), may change in minor versions without a deprecation period. It is marked by the `PyUnstable` prefix in names.
- [Limited API](#), is compatible across several minor releases. When `Py_LIMITED_API` is defined, only this subset is exposed from `Python.h`.

These are discussed in more detail below.

Names prefixed by an underscore, such as `_Py_InternalState`, are private API that can change without notice even in patch releases. If you need to use this API, consider reaching out to [CPython developers](https://discuss.python.org/c/core-dev/c-api/30) [https://discuss.python.org/c/core-dev/c-api/30] to discuss adding public API for your use case.

## Unstable C API

Any API named with the `PyUnstable` prefix exposes CPython implementation details, and may change in every minor release (e.g. from 3.9 to 3.10) without any deprecation warnings. However,

it will not change in a bugfix release (e.g. from 3.10.0 to 3.10.1).

It is generally intended for specialized, low-level tools like debuggers.

Projects that use this API are expected to follow CPython development and spend extra effort adjusting to changes.

## Stable Application Binary Interface

For simplicity, this document talks about *extensions*, but the Limited API and Stable ABI work the same way for all uses of the API – for example, embedding Python.

### Limited C API

Python 3.2 introduced the *Limited API*, a subset of Python’s C API. Extensions that only use the Limited API can be compiled once and work with multiple versions of Python. Contents of the Limited API are [listed below](#).

#### Py\_LIMITED\_API

Define this macro before including `Python.h` to opt in to only use the Limited API, and to select the Limited API version.

Define `Py_LIMITED_API` to the value of [PY\\_VERSION\\_HEX](#) corresponding to the lowest Python version your extension supports. The extension will work without recompilation with all Python 3 releases from the specified one onward, and can use Limited API introduced up to that version.

Rather than using the `PY_VERSION_HEX` macro directly, hardcode a minimum minor version (e.g. `0x030A0000` for Python 3.10) for stability when compiling with future Python versions.

You can also define `Py_LIMITED_API` to `3`. This works the same as `0x03020000` (Python 3.2, the version that introduced Limited API).

## Stable ABI

To enable this, Python provides a *Stable ABI*: a set of symbols that will remain compatible across Python 3.x versions.

The Stable ABI contains symbols exposed in the [Limited API](#), but also other ones – for example, functions necessary to support older versions of the Limited API.

On Windows, extensions that use the Stable ABI should be linked against `python3.dll` rather than a version-specific library such as `python39.dll`.

On some platforms, Python will look for and load shared library files named with the `abi3` tag (e.g. `mymodule.abi3.so`). It does not check if such extensions conform to a Stable ABI. The user (or their packaging tools) need to ensure that, for example, extensions built with the 3.10+ Limited API are not installed for lower versions of Python.

All functions in the Stable ABI are present as functions in Python’s shared library, not solely as macros. This makes them usable from languages that don’t use the C preprocessor.

## Limited API Scope and Performance

The goal for the Limited API is to allow everything that is possible with the full C API, but possibly with a performance penalty.

For example, while `PyList_GetItem()` is available, its “unsafe” macro variant `PyList_GET_ITEM()` is not. The macro can be faster because it can rely on version-specific implementation details of the list object.

Without `Py_LIMITED_API` defined, some C API functions are inlined or replaced by macros. Defining `Py_LIMITED_API` disables this inlining, allowing stability as Python’s data structures are improved, but possibly reducing performance.

By leaving out the `Py_LIMITED_API` definition, it is possible to compile a Limited API extension with a version-specific ABI. This

can improve performance for that Python version, but will limit compatibility. Compiling with `PY_LIMITED_API` will then yield an extension that can be distributed where a version-specific one is not available – for example, for prereleases of an upcoming Python version.

## Limited API Caveats

Note that compiling with `PY_LIMITED_API` is *not* a complete guarantee that code conforms to the [Limited API](#) or the [Stable ABI](#). `PY_LIMITED_API` only covers definitions, but an API also includes other issues, such as expected semantics.

One issue that `PY_LIMITED_API` does not guard against is calling a function with arguments that are invalid in a lower Python version. For example, consider a function that starts accepting `NULL` for an argument. In Python 3.9, `NULL` now selects a default behavior, but in Python 3.8, the argument will be used directly, causing a `NULL` dereference and crash. A similar argument works for fields of structs.

Another issue is that some struct fields are currently not hidden when `PY_LIMITED_API` is defined, even though they're part of the Limited API.

For these reasons, we recommend testing an extension with *all* minor Python versions it supports, and preferably to build with the *lowest* such version.

We also recommend reviewing documentation of all used API to check if it is explicitly part of the Limited API. Even with `PY_LIMITED_API` defined, a few private declarations are exposed for technical reasons (or even unintentionally, as bugs).

Also note that the Limited API is not necessarily stable: compiling with `PY_LIMITED_API` with Python 3.8 means that the extension will run with Python 3.12, but it will not necessarily *compile* with Python 3.12. In particular, parts of the Limited API may be deprecated and removed, provided that the Stable ABI stays stable.

# Platform Considerations

ABI stability depends not only on Python, but also on the compiler used, lower-level libraries and compiler options. For the purposes of the [Stable ABI](#), these details define a “platform”. They usually depend on the OS type and processor architecture

It is the responsibility of each particular distributor of Python to ensure that all Python versions on a particular platform are built in a way that does not break the Stable ABI. This is the case with Windows and macOS releases from `python.org` and many third-party distributors.

## Contents of Limited API

Currently, the [Limited API](#) includes the following items:

- `PY_VECTORCALL_ARGUMENTS_OFFSET`
- `PyAIter_Check()`
- `PyArg_Parse()`
- `PyArg_ParseTuple()`
- `PyArg_ParseTupleAndKeywords()`
- `PyArg_UnpackTuple()`
- `PyArg_VaParse()`
- `PyArg_VaParseTupleAndKeywords()`
- `PyArg_ValidateKeywordArguments()`
- `PyBaseObject_Type`
- `PyBool_FromLong()`
- `PyBool_Type`
- `PyBuffer_FillContiguousStrides()`
- `PyBuffer_FillInfo()`
- `PyBuffer_FromContiguous()`
- `PyBuffer_GetPointer()`
- `PyBuffer_IsContiguous()`
- `PyBuffer_Release()`
- `PyBuffer_SizeFromFormat()`
- `PyBuffer_ToContiguous()`
- `PyByteArrayIter_Type`
- `PyByteArray_AsString()`

- `PyByteArray_Concat()`
- `PyByteArray_FromObject()`
- `PyByteArray_FromStringAndSize()`
- `PyByteArray_Resize()`
- `PyByteArray_Size()`
- `PyByteArray_Type`
- `PyBytesIter_Type`
- `PyBytes_AsString()`
- `PyBytes_AsStringAndSize()`
- `PyBytes_Concat()`
- `PyBytes_ConcatAndDel()`
- `PyBytes_DecodeEscape()`
- `PyBytes_FromFormat()`
- `PyBytes_FromFormatV()`
- `PyBytes_FromObject()`
- `PyBytes_FromString()`
- `PyBytes_FromStringAndSize()`
- `PyBytes_Repr()`
- `PyBytes_Size()`
- `PyBytes_Type`
- `PyCFunction`
- `PyCFunctionWithKeywords`
- `PyCFunction_Call()`
- `PyCFunction_GetFlags()`
- `PyCFunction_GetFunction()`
- `PyCFunction_GetSelf()`
- `PyCFunction_New()`
- `PyCFunction_NewEx()`
- `PyCFunction_Type`
- `PyCMethod_New()`
- `PyCallIter_New()`
- `PyCallIter_Type`
- `PyCallable_Check()`
- `PyCapsule_Destructor`
- `PyCapsule_GetContext()`
- `PyCapsule_GetDestructor()`
- `PyCapsule_GetName()`
- `PyCapsule_GetPointer()`
- `PyCapsule_Import()`
- `PyCapsule_IsValid()`

- `PyCapsule_New()`
- `PyCapsule_SetContext()`
- `PyCapsule_SetDestructor()`
- `PyCapsule_SetName()`
- `PyCapsule_SetPointer()`
- `PyCapsule_Type`
- `PyClassMethodDescr_Type`
- `PyCodec_BackslashReplaceErrors()`
- `PyCodec_Decode()`
- `PyCodec_Decoder()`
- `PyCodec_Encode()`
- `PyCodec_Encoder()`
- `PyCodec_IgnoreErrors()`
- `PyCodec_IncrementalDecoder()`
- `PyCodec_IncrementalEncoder()`
- `PyCodec_KnownEncoding()`
- `PyCodec_LookupError()`
- `PyCodec_NameReplaceErrors()`
- `PyCodec_Register()`
- `PyCodec_RegisterError()`
- `PyCodec_ReplaceErrors()`
- `PyCodec_StreamReader()`
- `PyCodec_StreamWriter()`
- `PyCodec_StrictErrors()`
- `PyCodec_Unregister()`
- `PyCodec_XMLCharRefReplaceErrors()`
- `PyComplex_FromDoubles()`
- `PyComplex_ImagAsDouble()`
- `PyComplex_RealAsDouble()`
- `PyComplex_Type`
- `PyDescr_NewClassMethod()`
- `PyDescr_NewGetSet()`
- `PyDescr_NewMember()`
- `PyDescr_NewMethod()`
- `PyDictItems_Type`
- `PyDictIterItem_Type`
- `PyDictIterKey_Type`
- `PyDictIterValue_Type`
- `PyDictKeys_Type`
- `PyDictProxy_New()`

- `PyDictProxy_Type`
- `PyDictRevIterItem_Type`
- `PyDictRevIterKey_Type`
- `PyDictRevIterValue_Type`
- `PyDictValues_Type`
- `PyDict_Clear()`
- `PyDict_Contains()`
- `PyDict_Copy()`
- `PyDict_DelItem()`
- `PyDict_DelItemString()`
- `PyDict_GetItem()`
- `PyDict_GetItemString()`
- `PyDict_GetItemWithError()`
- `PyDict_Items()`
- `PyDict_Keys()`
- `PyDict_Merge()`
- `PyDict_MergeFromSeq2()`
- `PyDict_New()`
- `PyDict_Next()`
- `PyDict_SetItem()`
- `PyDict_SetItemString()`
- `PyDict_Size()`
- `PyDict_Type`
- `PyDict_Update()`
- `PyDict_Values()`
- `PyEllipsis_Type`
- `PyEnum_Type`
- `PyErr_BadArgument()`
- `PyErr_BadInternalCall()`
- `PyErr_CheckSignals()`
- `PyErr_Clear()`
- `PyErr_Display()`
- `PyErr_DisplayException()`
- `PyErr_ExceptionMatches()`
- `PyErr_Fetch()`
- `PyErr_Format()`
- `PyErr_FormatV()`
- `PyErr_GetExcInfo()`
- `PyErr_GetHandledException()`
- `PyErr_GetRaisedException()`

- `PyErr_GivenExceptionMatches()`
- `PyErr_NewException()`
- `PyErr_NewExceptionWithDoc()`
- `PyErr_NoMemory()`
- `PyErr_NormalizeException()`
- `PyErr_Occurred()`
- `PyErr_Print()`
- `PyErr_PrintEx()`
- `PyErr_ProgramText()`
- `PyErr_ResourceWarning()`
- `PyErr_Restore()`
- `PyErr_SetExcFromWindowsErr()`
- `PyErr_SetExcFromWindowsErrWithFilename()`
- `PyErr_SetExcFromWindowsErrWithFilenameObject()`
- `PyErr_SetExcFromWindowsErrWithFilenameObjects()`
- `PyErr_SetExcInfo()`
- `PyErr_SetFromErrno()`
- `PyErr_SetFromErrnoWithFilename()`
- `PyErr_SetFromErrnoWithFilenameObject()`
- `PyErr_SetFromErrnoWithFilenameObjects()`
- `PyErr_SetFromWindowsErr()`
- `PyErr_SetFromWindowsErrWithFilename()`
- `PyErr_SetHandledException()`
- `PyErr_SetImportError()`
- `PyErr_SetImportErrorSubclass()`

# The Very High Level Layer

The functions in this chapter will let you execute Python source code given in a file or a buffer, but they will not let you interact in a more detailed way with the interpreter.

Several of these functions accept a start symbol from the grammar as a parameter. The available start symbols are `Py_eval_input`, `Py_file_input`, and `Py_single_input`. These are described following the functions which accept them as parameters.

Note also that several of these functions take `FILE*` parameters. One particular issue which needs to be handled carefully is that the **FILE** structure for different C libraries can be different and incompatible. Under Windows (at least), it is possible for dynamically linked extensions to actually use different libraries, so care should be taken that `FILE*` parameters are only passed to these functions if it is certain that they were created by the same library that the Python runtime is using.

```
int Py_Main(int argc, wchar_t **argv)
```

*Part of the [Stable ABI](#).*

The main program for the standard interpreter. This is made available for programs which embed Python. The `argc` and `argv` parameters should be prepared exactly as those which are passed to a C program's `main()` function (converted to `wchar_t` according to the user's locale). It is important to note that the argument list may be modified (but the contents of the strings pointed to by the argument list are not). The return value will be `0` if the interpreter exits normally (i.e., without an exception), `1` if the interpreter exits due to an exception, or `2` if the parameter list does not represent a valid Python command line.

Note that if an otherwise unhandled `SystemExit` is raised, this function will not return `1`, but exit the process, as long

as `PyConfig.inspect` is zero.

`int Py_BytesMain(int argc, char **argv)`

Part of the *Stable ABI* since version 3.8.

Similar to `Py_Main()` but *argv* is an array of bytes strings.

*New in version 3.8.*

`int PyRun_AnyFile(FILE *fp, const char *filename)`

This is a simplified interface to `PyRun_AnyFileExFlags()` below, leaving *closeit* set to 0 and *flags* set to `NULL`.

`int PyRun_AnyFileFlags(FILE *fp, const char *filename,  
PyCompilerFlags *flags)`

This is a simplified interface to `PyRun_AnyFileExFlags()` below, leaving the *closeit* argument set to 0.

`int PyRun_AnyFileEx(FILE *fp, const char *filename, int closeit)`

This is a simplified interface to `PyRun_AnyFileExFlags()` below, leaving the *flags* argument set to `NULL`.

`int PyRun_AnyFileExFlags(FILE *fp, const char *filename, int  
closeit, PyCompilerFlags *flags)`

If *fp* refers to a file associated with an interactive device (console or terminal input or Unix pseudo-terminal), return the value of `PyRun_InteractiveLoop()`, otherwise return the result of `PyRun_SimpleFile()`. *filename* is decoded from the filesystem encoding (`sys.getfilesystemencoding()`). If *filename* is `NULL`, this function uses "???" as the filename. If *closeit* is true, the file is closed before `PyRun_SimpleFileExFlags()` returns.

`int PyRun_SimpleString(const char *command)`

This is a simplified interface to `PyRun_SimpleStringFlags()` below, leaving the

`PyCompilerFlags`\* argument set to `NULL`.

`int PyRun_SimpleStringFlags(const char *command,  
PyCompilerFlags *flags)`

Executes the Python source code from *command* in the `__main__` module according to the *flags* argument. If `__main__` does not already exist, it is created. Returns `0` on success or `-1` if an exception was raised. If there was an error, there is no way to get the exception information. For the meaning of *flags*, see below.

Note that if an otherwise unhandled `SystemExit` is raised, this function will not return `-1`, but exit the process, as long as `PyConfig.inspect` is zero.

`int PyRun_SimpleFile(FILE *fp, const char *filename)`

This is a simplified interface to `PyRun_SimpleFileExFlags()` below, leaving *closeit* set to `0` and *flags* set to `NULL`.

`int PyRun_SimpleFileEx(FILE *fp, const char *filename, int closeit)`

This is a simplified interface to `PyRun_SimpleFileExFlags()` below, leaving *flags* set to `NULL`.

`int PyRun_SimpleFileExFlags(FILE *fp, const char *filename, int closeit, PyCompilerFlags *flags)`

Similar to `PyRun_SimpleStringFlags()`, but the Python source code is read from *fp* instead of an in-memory string. *filename* should be the name of the file, it is decoded from [filesystem encoding and error handler](#). If *closeit* is true, the file is closed before `PyRun_SimpleFileExFlags()` returns.

### Note

On Windows, *fp* should be opened as binary mode (e.g. `fopen(filename, "rb")`). Otherwise, Python may not

handle script file with LF line ending correctly.

`int PyRun_InteractiveOne(FILE *fp, const char *filename)`

This is a simplified interface to

`PyRun_InteractiveOneFlags()` below, leaving *flags* set to `NULL`.

`int PyRun_InteractiveOneFlags(FILE *fp, const char *filename,  
PyCompilerFlags *flags)`

Read and execute a single statement from a file associated with an interactive device according to the *flags* argument. The user will be prompted using `sys.ps1` and `sys.ps2`. *filename* is decoded from the [filesystem encoding and error handler](#).

Returns `0` when the input was executed successfully, `-1` if there was an exception, or an error code from the `errcode.h` include file distributed as part of Python if there was a parse error. (Note that `errcode.h` is not included by `Python.h`, so must be included specifically if needed.)

`int PyRun_InteractiveLoop(FILE *fp, const char *filename)`

This is a simplified interface to

`PyRun_InteractiveLoopFlags()` below, leaving *flags* set to `NULL`.

`int PyRun_InteractiveLoopFlags(FILE *fp, const char *filename,  
PyCompilerFlags *flags)`

Read and execute statements from a file associated with an interactive device until EOF is reached. The user will be prompted using `sys.ps1` and `sys.ps2`. *filename* is decoded from the [filesystem encoding and error handler](#). Returns `0` at EOF or a negative number upon failure.

`int (*PyOS_InputHook)(void)`

Part of the [Stable ABI](#).

Can be set to point to a function with the prototype `int func(void)`. The function will be called when Python's interpreter prompt is about to become idle and wait for user input from the terminal. The return value is ignored. Overriding this hook can be used to integrate the interpreter's prompt with other event loops, as done in the `Modules/_tkinter.c` in the Python source code.

*Changed in version 3.12:* This function is only called from the [main interpreter](#).

`char *(*PyOS_ReadlineFunctionPointer)(FILE*, FILE*, const char*)`

Can be set to point to a function with the prototype `char *func(FILE *stdin, FILE *stdout, char *prompt)`, overriding the default function used to read a single line of input at the interpreter's prompt. The function is expected to output the string *prompt* if it's not `NULL`, and then read a line of input from the provided standard input file, returning the resulting string. For example, The [readline](#) module sets this hook to provide line-editing and tab-completion features.

The result must be a string allocated by [PyMem\\_RawMalloc\(\)](#) or [PyMem\\_RawRealloc\(\)](#), or `NULL` if an error occurred.

*Changed in version 3.4:* The result must be allocated by [PyMem\\_RawMalloc\(\)](#) or [PyMem\\_RawRealloc\(\)](#), instead of being allocated by [PyMem\\_Malloc\(\)](#) or [PyMem\\_Realloc\(\)](#).

*Changed in version 3.12:* This function is only called from the [main interpreter](#).

`PyObject *PyRun_String(const char *str, int start, PyObject *globals, PyObject *locals)`

*Return value:* New reference.

This is a simplified interface to [PyRun\\_StringFlags\(\)](#) below, leaving *flags* set to `NULL`.

**PyObject** \*PyRun\_StringFlags(const char \*str, int start, **PyObject** \*globals, **PyObject** \*locals, **PyCompilerFlags** \*flags)

*Return value:* New reference.

Execute Python source code from *str* in the context specified by the objects *globals* and *locals* with the compiler flags specified by *flags*. *globals* must be a dictionary; *locals* can be any object that implements the mapping protocol. The parameter *start* specifies the start token that should be used to parse the source code.

Returns the result of executing the code as a Python object, or NULL if an exception was raised.

**PyObject** \*PyRun\_File(FILE \*fp, const char \*filename, int start, **PyObject** \*globals, **PyObject** \*locals)

*Return value:* New reference.

This is a simplified interface to **PyRun\_FileExFlags()** below, leaving *closeit* set to 0 and *flags* set to NULL.

**PyObject** \*PyRun\_FileEx(FILE \*fp, const char \*filename, int start, **PyObject** \*globals, **PyObject** \*locals, int closeit)

*Return value:* New reference.

This is a simplified interface to **PyRun\_FileExFlags()** below, leaving *flags* set to NULL.

**PyObject** \*PyRun\_FileFlags(FILE \*fp, const char \*filename, int start, **PyObject** \*globals, **PyObject** \*locals, **PyCompilerFlags** \*flags)

*Return value:* New reference.

This is a simplified interface to **PyRun\_FileExFlags()** below, leaving *closeit* set to 0.

**PyObject** \*PyRun\_FileExFlags(FILE \*fp, const char \*filename, int start, **PyObject** \*globals, **PyObject** \*locals, int closeit, **PyCompilerFlags** \*flags)

*Return value:* New reference.

Similar to **PyRun\_StringFlags()**, but the Python source

code is read from *fp* instead of an in-memory string. *filename* should be the name of the file, it is decoded from the [filesystem encoding and error handler](#). If *closeit* is true, the file is closed before [PyRun\\_FileExFlags\(\)](#) returns.

**PyObject** \*Py\_CompileString(const char \*str, const char \*filename, int start)

*Return value:* New reference. Part of the [Stable ABI](#).

This is a simplified interface to

[Py\\_CompileStringFlags\(\)](#) below, leaving *flags* set to NULL.

**PyObject** \*Py\_CompileStringFlags(const char \*str, const char \*filename, int start, [PyCompilerFlags](#) \*flags)

*Return value:* New reference.

This is a simplified interface to

[Py\\_CompileStringExFlags\(\)](#) below, with *optimize* set to -1.

**PyObject** \*Py\_CompileStringObject(const char \*str, **PyObject** \*filename, int start, [PyCompilerFlags](#) \*flags, int optimize)

*Return value:* New reference.

Parse and compile the Python source code in *str*, returning the resulting code object. The start token is given by *start*; this can be used to constrain the code which can be compiled and should be [Py\\_eval\\_input](#), [Py\\_file\\_input](#), or [Py\\_single\\_input](#). The filename specified by *filename* is used to construct the code object and may appear in tracebacks or [SyntaxError](#) exception messages. This returns NULL if the code cannot be parsed or compiled.

The integer *optimize* specifies the optimization level of the compiler; a value of -1 selects the optimization level of the interpreter as given by [-O](#) options. Explicit levels are 0 (no optimization; `__debug__` is true), 1 (asserts are removed, `__debug__` is false) or 2 (docstrings are removed too).

*New in version 3.4.*

**PyObject** \*Py\_CompileStringExFlags(const char \*str, const char \*filename, int start, **PyCompilerFlags** \*flags, int optimize)

*Return value: New reference.*

Like **Py\_CompileStringObject()**, but *filename* is a byte string decoded from the [filesystem encoding and error handler](#).

*New in version 3.2.*

**PyObject** \*PyEval\_EvalCode(**PyObject** \*co, **PyObject** \*globals, **PyObject** \*locals)

*Return value: New reference. Part of the [Stable ABI](#).*

This is a simplified interface to **PyEval\_EvalCodeEx()**, with just the code object, and global and local variables. The other arguments are set to `NULL`.

**PyObject** \*PyEval\_EvalCodeEx(**PyObject** \*co, **PyObject** \*globals, **PyObject** \*locals, **PyObject** \*const \*args, int argcount, **PyObject** \*const \*kws, int kwcount, **PyObject** \*const \*defs, int defcount, **PyObject** \*kwdefs, **PyObject** \*closure)

*Return value: New reference. Part of the [Stable ABI](#).*

Evaluate a precompiled code object, given a particular environment for its evaluation. This environment consists of a dictionary of global variables, a mapping object of local variables, arrays of arguments, keywords and defaults, a dictionary of default values for [keyword-only](#) arguments and a closure tuple of cells.

**PyObject** \*PyEval\_EvalFrame(**PyFrameObject** \*f)

*Return value: New reference. Part of the [Stable ABI](#).*

Evaluate an execution frame. This is a simplified interface to **PyEval\_EvalFrameEx()**, for backward compatibility.

**PyObject** \*PyEval\_EvalFrameEx(**PyFrameObject** \*f, int throwflag)

*Return value: New reference. Part of the [Stable ABI](#).*

This is the main, unvarnished function of Python interpretation. The code object associated with the execution

frame *f* is executed, interpreting bytecode and executing calls as needed. The additional *throwflag* parameter can mostly be ignored - if true, then it causes an exception to immediately be thrown; this is used for the `throw()` methods of generator objects.

*Changed in version 3.4:* This function now includes a debug assertion to help ensure that it does not silently discard an active exception.

`int PyEval_MergeCompilerFlags(PyCompilerFlags *cf)`

This function changes the flags of the current evaluation frame, and returns true on success, false on failure.

`int Py_eval_input`

The start symbol from the Python grammar for isolated expressions; for use with `Py_CompileString()`.

`int Py_file_input`

The start symbol from the Python grammar for sequences of statements as read from a file or other source; for use with `Py_CompileString()`. This is the symbol to use when compiling arbitrarily long Python source code.

`int Py_single_input`

The start symbol from the Python grammar for a single statement; for use with `Py_CompileString()`. This is the symbol used for the interactive interpreter loop.

`struct PyCompilerFlags`

This is the structure used to hold compiler flags. In cases where code is only being compiled, it is passed as `int flags`, and in cases where code is being executed, it is passed as `PyCompilerFlags *flags`. In this case, from `__future__` import can modify *flags*.

Whenever `PyCompilerFlags *flags` is NULL, `cf_flags` is treated as equal to 0, and any modification due

to `from __future__ import` is discarded.

`int cf_flags`

Compiler flags.

`int cf_feature_version`

*cf\_feature\_version* is the minor Python version. It should be initialized to `PY_MINOR_VERSION`.

The field is ignored by default, it is used if and only if `PyCF_ONLY_AST` flag is set in `cf_flags`.

*Changed in version 3.8:* Added *cf\_feature\_version* field.

`int CO_FUTURE_DIVISION`

This bit can be set in *flags* to cause division operator `/` to be interpreted as “true division” according to [PEP 238](https://peps.python.org/pep-0238/) [https://peps.python.org/pep-0238/].

# Reference Counting

The functions and macros in this section are used for managing reference counts of Python objects.

`Py_ssize_t Py_REFCNT(PyObject *o)`

Get the reference count of the Python object *o*.

Note that the returned value may not actually reflect how many references to the object are actually held. For example, some objects are “immortal” and have a very high refcount that does not reflect the actual number of references. Consequently, do not rely on the returned value to be accurate, other than a value of 0 or 1.

Use the `Py_SET_REFCNT()` function to set an object reference count.

*Changed in version 3.11:* The parameter type is no longer `const PyObject*`.

*Changed in version 3.10:* `Py_REFCNT()` is changed to the inline static function.

`void Py_SET_REFCNT(PyObject *o, Py_ssize_t refcnt)`

Set the object *o* reference counter to *refcnt*.

Note that this function has no effect on `immortal` [<https://peps.python.org/pep-0683/>] objects.

*New in version 3.9.*

*Changed in version 3.12:* Immortal objects are not modified.

`void Py_INCREF(PyObject *o)`

Indicate taking a new **strong reference** to object *o*, indicating

it is in use and should not be destroyed.

This function is usually used to convert a [borrowed reference](#) to a [strong reference](#) in-place. The `Py_NewRef()` function can be used to create a new [strong reference](#).

When done using the object, release it by calling `Py_DECREF()`.

The object must not be `NULL`; if you aren't sure that it isn't `NULL`, use `Py_XINCRF()`.

Do not expect this function to actually modify *o* in any way. For at least [some objects](#) [<https://peps.python.org/pep-0683/>], this function has no effect.

*Changed in version 3.12:* Immortal objects are not modified.

`void Py_XINCRF(PyObject *o)`

Similar to `Py_INCRF()`, but the object *o* can be `NULL`, in which case this has no effect.

See also `Py_XNewRef()`.

`PyObject *Py_NewRef(PyObject *o)`

*Part of the [Stable ABI](#) since version 3.10.*

Create a new [strong reference](#) to an object: call `Py_INCRF()` on *o* and return the object *o*.

When the [strong reference](#) is no longer needed, `Py_DECREF()` should be called on it to release the reference.

The object *o* must not be `NULL`; use `Py_XNewRef()` if *o* can be `NULL`.

For example:

```
Py_INCREF(obj);  
self->attr = obj;
```

can be written as:

```
self->attr = Py_NewRef(obj);
```

See also `Py_INCREF()`.

*New in version 3.10.*

`PyObject *Py_XNewRef(PyObject *o)`

Part of the *Stable ABI* since version 3.10.

Similar to `Py_NewRef()`, but the object `o` can be `NULL`.

If the object `o` is `NULL`, the function just returns `NULL`.

*New in version 3.10.*

`void Py_DECREF(PyObject *o)`

Release a [strong reference](#) to object `o`, indicating the reference is no longer used.

Once the last [strong reference](#) is released (i.e. the object's reference count reaches 0), the object's type's deallocation function (which must not be `NULL`) is invoked.

This function is usually used to delete a [strong reference](#) before exiting its scope.

The object must not be `NULL`; if you aren't sure that it isn't `NULL`, use `Py_XDECREF()`.

Do not expect this function to actually modify `o` in any way. For at least [some objects](https://peps.python.org/pep-0683/) [https://peps.python.org/pep-0683/], this function has no effect.

## Warning

The deallocation function can cause arbitrary Python code to be invoked (e.g. when a class instance with a `__del__()` method is deallocated). While exceptions in such code are not propagated, the executed code has free access to all Python global variables. This means that any object that is reachable from a global variable should be in

a consistent state before `Py_DECREF()` is invoked. For example, code to delete an object from a list should copy a reference to the deleted object in a temporary variable, update the list data structure, and then call `Py_DECREF()` for the temporary variable.

*Changed in version 3.12:* Immortal objects are not modified.

`void Py_XDECREF(PyObject *o)`

Similar to `Py_DECREF()`, but the object `o` can be `NULL`, in which case this has no effect. The same warning from `Py_DECREF()` applies here as well.

`void Py_CLEAR(PyObject *o)`

Release a [strong reference](#) for object `o`. The object may be `NULL`, in which case the macro has no effect; otherwise the effect is the same as for `Py_DECREF()`, except that the argument is also set to `NULL`. The warning for `Py_DECREF()` does not apply with respect to the object passed because the macro carefully uses a temporary variable and sets the argument to `NULL` before releasing the reference.

It is a good idea to use this macro whenever releasing a reference to an object that might be traversed during garbage collection.

*Changed in version 3.12:* The macro argument is now only evaluated once. If the argument has side effects, these are no longer duplicated.

`void Py_IncRef(PyObject *o)`

Part of the [Stable ABI](#).

Indicate taking a new [strong reference](#) to object `o`. A function version of `Py_XINCREF()`. It can be used for runtime dynamic embedding of Python.

`void Py_DecRef(PyObject *o)`

Part of the *Stable ABI*.

Release a [strong reference](#) to object *o*. A function version of [Py\\_XDECREF\(\)](#). It can be used for runtime dynamic embedding of Python.

`Py_SETREF(dst, src)`

Macro safely releasing a [strong reference](#) to object *dst* and setting *dst* to *src*.

As in case of [Py\\_CLEAR\(\)](#), “the obvious” code can be deadly:

```
Py_DECREF(dst);  
dst = src;
```

The safe way is:

```
Py_SETREF(dst, src);
```

That arranges to set *dst* to *src* *before* releasing the reference to the old value of *dst*, so that any code triggered as a side-effect of *dst* getting torn down no longer believes *dst* points to a valid object.

*New in version 3.6.*

*Changed in version 3.12:* The macro arguments are now only evaluated once. If an argument has side effects, these are no longer duplicated.

`Py_XSETREF(dst, src)`

Variant of [Py\\_SETREF](#) macro that uses [Py\\_XDECREF\(\)](#) instead of [Py\\_DECREF\(\)](#).

*New in version 3.6.*

*Changed in version 3.12:* The macro arguments are now only evaluated once. If an argument has side effects, these are no longer duplicated.

# Exception Handling

The functions described in this chapter will let you handle and raise Python exceptions. It is important to understand some of the basics of Python exception handling. It works somewhat like the POSIX `errno` variable: there is a global indicator (per thread) of the last error that occurred. Most C API functions don't clear this on success, but will set it to indicate the cause of the error on failure. Most C API functions also return an error indicator, usually `NULL` if they are supposed to return a pointer, or `-1` if they return an integer (exception: the `PyArg_*` functions return `1` for success and `0` for failure).

Concretely, the error indicator consists of three object pointers: the exception's type, the exception's value, and the traceback object. Any of those pointers can be `NULL` if non-set (although some combinations are forbidden, for example you can't have a non-`NULL` traceback if the exception type is `NULL`).

When a function must fail because some function it called failed, it generally doesn't set the error indicator; the function it called already set it. It is responsible for either handling the error and clearing the exception or returning after cleaning up any resources it holds (such as object references or memory allocations); it should *not* continue normally if it is not prepared to handle the error. If returning due to an error, it is important to indicate to the caller that an error has been set. If the error is not handled or carefully propagated, additional calls into the Python/C API may not behave as intended and may fail in mysterious ways.

## Note

The error indicator is **not** the result of `sys.exc_info()`. The former corresponds to an exception that is not yet caught (and is therefore still propagating), while the latter returns an exception after it is caught (and has therefore stopped propagating).

# Printing and clearing

`void PyErr_Clear()`

*Part of the [Stable ABI](#).*

Clear the error indicator. If the error indicator is not set, there is no effect.

`void PyErr_PrintEx(int set_sys_last_vars)`

*Part of the [Stable ABI](#).*

Print a standard traceback to `sys.stderr` and clear the error indicator. **Unless** the error is a `SystemExit`, in that case no traceback is printed and the Python process will exit with the error code specified by the `SystemExit` instance.

Call this function **only** when the error indicator is set. Otherwise it will cause a fatal error!

If `set_sys_last_vars` is nonzero, the variable `sys.last_exc` is set to the printed exception. For backwards compatibility, the deprecated variables `sys.last_type`, `sys.last_value` and `sys.last_traceback` are also set to the type, value and traceback of this exception, respectively.

*Changed in version 3.12:* The setting of `sys.last_exc` was added.

`void PyErr_Print()`

*Part of the [Stable ABI](#).*

Alias for `PyErr_PrintEx(1)`.

`void PyErr_WriteUnraisable(PyObject *obj)`

*Part of the [Stable ABI](#).*

Call `sys.unraisablehook()` using the current exception and `obj` argument.

This utility function prints a warning message to `sys.stderr` when an exception has been set but it is impossible for the interpreter to actually raise the exception.

It is used, for example, when an exception occurs in an `__del__()` method.

The function is called with a single argument *obj* that identifies the context in which the unraisable exception occurred. If possible, the repr of *obj* will be printed in the warning message.

An exception must be set when calling this function.

`void PyErr_DisplayException(PyObject *exc)`

*Part of the [Stable ABI](#) since version 3.12.*

Print the standard traceback display of `exc` to `sys.stderr`, including chained exceptions and notes.

*New in version 3.12.*

## Raising exceptions

These functions help you set the current thread's error indicator. For convenience, some of these functions will always return a `NULL` pointer for use in a `return` statement.

`void PyErr_SetString(PyObject *type, const char *message)`

*Part of the [Stable ABI](#).*

This is the most common way to set the error indicator. The first argument specifies the exception type; it is normally one of the standard exceptions, e.g. `PyExc_RuntimeError`. You need not create a new [strong reference](#) to it (e.g. with `Py_INCREF()`). The second argument is an error message; it is decoded from `'utf-8'`.

`void PyErr_SetObject(PyObject *type, PyObject *value)`

*Part of the [Stable ABI](#).*

This function is similar to `PyErr_SetString()` but lets you specify an arbitrary Python object for the “value” of the exception.

`PyObject *PyErr_Format(PyObject *exception, const char *format, ...)`

*Return value:* Always NULL. Part of the [Stable ABI](#).

This function sets the error indicator and returns NULL.

`exception` should be a Python exception class. The `format` and subsequent parameters help format the error message; they have the same meaning and values as in

`PyUnicode_FromFormat()`. `format` is an ASCII-encoded string.

`PyObject *PyErr_FormatV(PyObject *exception, const char *format, va_list vars)`

*Return value:* Always NULL. Part of the [Stable ABI](#) since version 3.5.

Same as `PyErr_Format()`, but taking a `va_list` argument rather than a variable number of arguments.

*New in version 3.5.*

`void PyErr_SetNone(PyObject *type)`

*Part of the [Stable ABI](#).*

This is a shorthand for `PyErr_SetObject(type, Py_None)`.

`int PyErr_BadArgument()`

*Part of the [Stable ABI](#).*

This is a shorthand for

`PyErr_SetString(PyExc_TypeError, message)`, where `message` indicates that a built-in operation was invoked with an illegal argument. It is mostly for internal use.

`PyObject *PyErr_NoMemory()`

*Return value:* Always NULL. Part of the [Stable ABI](#).

This is a shorthand for

`PyErr_SetNone(PyExc_MemoryError)`; it returns NULL so an object allocation function can write `return PyErr_NoMemory()`; when it runs out of memory.

`PyObject *PyErr_SetFromErrno(PyObject *type)`

*Return value:* Always `NULL`. Part of the *Stable ABI*.

This is a convenience function to raise an exception when a C library function has returned an error and set the C variable `errno`. It constructs a tuple object whose first item is the integer `errno` value and whose second item is the corresponding error message (gotten from `strerror()`), and then calls `PyErr_SetObject(type, object)`. On Unix, when the `errno` value is `EINTR`, indicating an interrupted system call, this calls `PyErr_CheckSignals()`, and if that set the error indicator, leaves it set to that. The function always returns `NULL`, so a wrapper function around a system call can write `return PyErr_SetFromErrno(type);` when the system call returns an error.

`PyObject *PyErr_SetFromErrnoWithFilenameObject(PyObject *type, PyObject *filenameObject)`

*Return value:* Always `NULL`. Part of the *Stable ABI*.

Similar to `PyErr_SetFromErrno()`, with the additional behavior that if `filenameObject` is not `NULL`, it is passed to the constructor of `type` as a third parameter. In the case of `OSError` exception, this is used to define the `filename` attribute of the exception instance.

`PyObject *PyErr_SetFromErrnoWithFilenameObjects(PyObject *type, PyObject *filenameObject, PyObject *filenameObject2)`

*Return value:* Always `NULL`. Part of the *Stable ABI* since version 3.7.

Similar to

`PyErr_SetFromErrnoWithFilenameObject()`, but takes a second filename object, for raising errors when a function that takes two filenames fails.

*New in version 3.4.*

`PyObject *PyErr_SetFromErrnoWithFilename(PyObject *type, const char *filename)`

*Return value: Always NULL. Part of the [Stable ABI](#).*

Similar to

[PyErr\\_SetFromErrnoWithFilenameObject\(\)](#), but the filename is given as a C string. *filename* is decoded from the filesystem encoding and error handler.

**PyObject \***[PyErr\\_SetFromWindowsErr](#)(int ierr)

*Return value: Always NULL. Part of the [Stable ABI](#) on Windows since version 3.7.*

This is a convenience function to raise [WindowsError](#). If called with *ierr* of 0, the error code returned by a call to [GetLastError\(\)](#) is used instead. It calls the Win32 function [FormatMessage\(\)](#) to retrieve the Windows description of error code given by *ierr* or [GetLastError\(\)](#), then it constructs a tuple object whose first item is the *ierr* value and whose second item is the corresponding error message (gotten from [FormatMessage\(\)](#)), and then calls

[PyErr\\_SetObject\(PyExc\\_WindowsError, object\)](#).

This function always returns NULL.

[Availability](#): Windows.

**PyObject \***[PyErr\\_SetExcFromWindowsErr](#)([PyObject \\*](#)type, int ierr)

*Return value: Always NULL. Part of the [Stable ABI](#) on Windows since version 3.7.*

Similar to [PyErr\\_SetFromWindowsErr\(\)](#), with an additional parameter specifying the exception type to be raised.

[Availability](#): Windows.

**PyObject \***[PyErr\\_SetFromWindowsErrWithFilename](#)(int ierr, const char \*filename)

*Return value: Always NULL. Part of the [Stable ABI](#) on Windows since version 3.7.*

Similar to [PyErr\\_SetFromWindowsErr\(\)](#), with the additional behavior that if *filename* is not NULL, it is decoded from the filesystem encoding ([os.fsdecode\(\)](#)) and passed

to the constructor of **OSError** as a third parameter to be used to define the **filename** attribute of the exception instance.

**Availability:** Windows.

## PyObject

**\*PyErr\_SetExcFromWindowsErrWithFilenameObject(PyObject \*type, int ierr, PyObject \*filename)**

*Return value:* Always NULL. Part of the *Stable ABI* on Windows since version 3.7.

Similar to **PyErr\_SetExcFromWindowsErr()**, with the additional behavior that if *filename* is not NULL, it is passed to the constructor of **OSError** as a third parameter to be used to define the **filename** attribute of the exception instance.

**Availability:** Windows.

## PyObject

**\*PyErr\_SetExcFromWindowsErrWithFilenameObjects(PyObject \*type, int ierr, PyObject \*filename, PyObject \*filename2)**

*Return value:* Always NULL. Part of the *Stable ABI* on Windows since version 3.7.

Similar to

**PyErr\_SetExcFromWindowsErrWithFilenameObject()**, but accepts a second filename object.

**Availability:** Windows.

*New in version 3.4.*

**PyObject \*PyErr\_SetExcFromWindowsErrWithFilename(PyObject \*type, int ierr, const char \*filename)**

*Return value:* Always NULL. Part of the *Stable ABI* on Windows since version 3.7.

Similar to **PyErr\_SetFromWindowsErrWithFilename()**, with an additional parameter specifying the exception type to

be raised.

**Availability:** Windows.

`PyObject *PyErr_SetImportError(PyObject *msg, PyObject *name, PyObject *path)`

*Return value:* Always NULL. Part of the [Stable ABI](#) since version 3.7.

This is a convenience function to raise `ImportError`. `msg` will be set as the exception's message string. `name` and `path`, both of which can be NULL, will be set as the `ImportError`'s respective `name` and `path` attributes.

*New in version 3.3.*

`PyObject *PyErr_SetImportErrorSubclass(PyObject *exception, PyObject *msg, PyObject *name, PyObject *path)`

*Return value:* Always NULL. Part of the [Stable ABI](#) since version 3.6.

Much like `PyErr_SetImportError()` but this function allows for specifying a subclass of `ImportError` to raise.

*New in version 3.6.*

`void PyErr_SyntaxLocationObject(PyObject *filename, int lineno, int col_offset)`

Set file, line, and offset information for the current exception. If the current exception is not a `SyntaxError`, then it sets additional attributes, which make the exception printing subsystem think the exception is a `SyntaxError`.

*New in version 3.4.*

`void PyErr_SyntaxLocationEx(const char *filename, int lineno, int col_offset)`

Part of the [Stable ABI](#) since version 3.7.

Like `PyErr_SyntaxLocationObject()`, but `filename` is a byte string decoded from the [filesystem encoding and error](#)

handler.

*New in version 3.2.*

`void PyErr_SyntaxLocation(const char *filename, int lineno)`

*Part of the [Stable ABI](#).*

Like `PyErr_SyntaxLocationEx()`, but the `col_offset` parameter is omitted.

`void PyErr_BadInternalCall()`

*Part of the [Stable ABI](#).*

This is a shorthand for

`PyErr_SetString(PyExc_SystemError, message)`, where *message* indicates that an internal operation (e.g. a Python/C API function) was invoked with an illegal argument. It is mostly for internal use.

## Issuing warnings

Use these functions to issue warnings from C code. They mirror similar functions exported by the Python [warnings](#) module. They normally print a warning message to `sys.stderr`; however, it is also possible that the user has specified that warnings are to be turned into errors, and in that case they will raise an exception. It is also possible that the functions raise an exception because of a problem with the warning machinery. The return value is `0` if no exception is raised, or `-1` if an exception is raised. (It is not possible to determine whether a warning message is actually printed, nor what the reason is for the exception; this is intentional.) If an exception is raised, the caller should do its normal exception handling (for example, `Py_DECREF()` owned references and return an error value).

`int PyErr_WarnEx(PyObject *category, const char *message,  
Py\_ssize\_t stack_level)`

*Part of the [Stable ABI](#).*

Issue a warning message. The *category* argument is a warning category (see below) or `NULL`; the *message* argument is a

UTF-8 encoded string. *stack\_level* is a positive number giving a number of stack frames; the warning will be issued from the currently executing line of code in that stack frame. A *stack\_level* of 1 is the function calling `PyErr_WarnEx()`, 2 is the function above that, and so forth.

Warning categories must be subclasses of `PyExc_Warning`; `PyExc_Warning` is a subclass of `PyExc_Exception`; the default warning category is `PyExc_RuntimeWarning`. The standard Python warning categories are available as global variables whose names are enumerated at [Standard Warning Categories](#).

For information about warning control, see the documentation for the `warnings` module and the `-W` option in the command line documentation. There is no C API for warning control.

```
int PyErr_WarnExplicitObject(PyObject *category, PyObject
*message, PyObject *filename, int lineno, PyObject *module,
PyObject *registry)
```

Issue a warning message with explicit control over all warning attributes. This is a straightforward wrapper around the Python function `warnings.warn_explicit()`; see there for more information. The *module* and *registry* arguments may be set to `NULL` to get the default effect described there.

*New in version 3.4.*

```
int PyErr_WarnExplicit(PyObject *category, const char *message,
const char *filename, int lineno, const char *module, PyObject
*registry)
```

*Part of the [Stable ABI](#).*

Similar to `PyErr_WarnExplicitObject()` except that *message* and *module* are UTF-8 encoded strings, and *filename* is decoded from the [filesystem encoding and error handler](#).

```
int PyErr_WarnFormat(PyObject *category, Py_ssize_t stack_level,
```

const char \*format, ...)

Part of the *Stable ABI*.

Function similar to `PyErr_WarnEx()`, but use `PyUnicode_FromFormat()` to format the warning message. `format` is an ASCII-encoded string.

*New in version 3.2.*

int PyErr\_ResourceWarning(PyObject \*source, Py\_ssize\_t stack\_level,  
const char \*format, ...)

Part of the *Stable ABI* since version 3.6.

Function similar to `PyErr_WarnFormat()`, but `category` is `ResourceWarning` and it passes `source` to `warnings.WarningMessage()`.

*New in version 3.6.*

## Querying the error indicator

PyObject \*PyErr\_Occurred()

*Return value:* Borrowed reference. Part of the *Stable ABI*.

Test whether the error indicator is set. If set, return the exception *type* (the first argument to the last call to one of the `PyErr_Set*` functions or to `PyErr_Restore()`). If not set, return `NULL`. You do not own a reference to the return value, so you do not need to `Py_DECREF()` it.

The caller must hold the GIL.

### Note

Do not compare the return value to a specific exception; use `PyErr_ExceptionMatches()` instead, shown below. (The comparison could easily fail since the exception may be an instance instead of a class, in the case of a class exception, or it may be a subclass of the expected exception.)

`int PyErr_ExceptionMatches(PyObject *exc)`

*Part of the [Stable ABI](#).*

Equivalent to

`PyErr_GivenExceptionMatches(PyErr_Occurred(), exc)`. This should only be called when an exception is actually set; a memory access violation will occur if no exception has been raised.

`int PyErr_GivenExceptionMatches(PyObject *given, PyObject *exc)`

*Part of the [Stable ABI](#).*

Return true if the *given* exception matches the exception type in *exc*. If *exc* is a class object, this also returns true when *given* is an instance of a subclass. If *exc* is a tuple, all exception types in the tuple (and recursively in subtuples) are searched for a match.

`PyObject *PyErr_GetRaisedException(void)`

*Return value: New reference. Part of the [Stable ABI](#) since version 3.12.*

Return the exception currently being raised, clearing the error indicator at the same time.

This function is used by code that needs to catch exceptions, or code that needs to save and restore the error indicator temporarily.

For example:

```
{
    PyObject *exc = PyErr_GetRaisedException();

    /* ... code that might produce other errors ...

    PyErr_SetRaisedException(exc);
}
```

**See also**

[`PyErr\_GetHandledException\(\)`](#), to save the exception

currently being handled.

*New in version 3.12.*

void PyErr\_SetRaisedException(PyObject \*exc)

Part of the *Stable ABI* since version 3.12.

Set *exc* as the exception currently being raised, clearing the existing exception if one is set.

### Warning

This call steals a reference to *exc*, which must be a valid exception.

*New in version 3.12.*

void PyErr\_Fetch(PyObject \*\*ptype, PyObject \*\*pvalue, PyObject \*\*ptraceback)

Part of the *Stable ABI*.

Deprecated since version 3.12: Use

[PyErr\\_GetRaisedException\(\)](#) instead.

Retrieve the error indicator into three variables whose addresses are passed. If the error indicator is not set, set all three variables to `NULL`. If it is set, it will be cleared and you own a reference to each object retrieved. The value and traceback object may be `NULL` even when the type object is not.

### Note

This function is normally only used by legacy code that needs to catch exceptions or save and restore the error indicator temporarily.

For example:

```
{
    PyObject *type, *value, *traceback;
```

```

    PyErr_Fetch(&type, &value, &traceback);

    /* ... code that might produce other errors ...

    PyErr_Restore(type, value, traceback);
}

```

void PyErr\_Restore(PyObject \*type, PyObject \*value, PyObject \*traceback)

*Part of the [Stable ABI](#).*

*Deprecated since version 3.12: Use*

[PyErr\\_SetRaisedException\(\)](#) instead.

Set the error indicator from the three objects, *type*, *value*, and *traceback*, clearing the existing exception if one is set. If the objects are NULL, the error indicator is cleared. Do not pass a NULL type and non-NULL value or traceback. The exception type should be a class. Do not pass an invalid exception type or value. (Violating these rules will cause subtle problems later.) This call takes away a reference to each object: you must own a reference to each object before the call and after the call you no longer own these references. (If you don't understand this, don't use this function. I warned you.)

## Note

This function is normally only used by legacy code that needs to save and restore the error indicator temporarily. Use [PyErr\\_Fetch\(\)](#) to save the current error indicator.

void PyErr\_NormalizeException(PyObject \*\*exc, PyObject \*\*val, PyObject \*\*tb)

*Part of the [Stable ABI](#).*

*Deprecated since version 3.12: Use*

[PyErr\\_GetRaisedException\(\)](#) instead, to avoid any possible de-normalization.

Under certain circumstances, the values returned by `PyErr_Fetch()` below can be “unnormalized”, meaning that `*exc` is a class object but `*val` is not an instance of the same class. This function can be used to instantiate the class in that case. If the values are already normalized, nothing happens. The delayed normalization is implemented to improve performance.

### Note

This function *does not* implicitly set the `__traceback__` attribute on the exception value. If setting the traceback appropriately is desired, the following additional snippet is needed:

```
if (tb != NULL) {  
    PyException_SetTraceback(val, tb);  
}
```

`PyObject *PyErr_GetHandledException(void)`

*Part of the [Stable ABI](#) since version 3.11.*

Retrieve the active exception instance, as would be returned by `sys.exception()`. This refers to an exception that was *already caught*, not to an exception that was freshly raised. Returns a new reference to the exception or `NULL`. Does not modify the interpreter’s exception state.

### Note

This function is not normally used by code that wants to handle exceptions. Rather, it can be used when code needs to save and restore the exception state temporarily. Use `PyErr_SetHandledException()` to restore or clear the exception state.

*New in version 3.11.*

`void PyErr_SetHandledException(PyObject *exc)`

Part of the *Stable ABI* since version 3.11.

Set the active exception, as known from `sys.exception()`. This refers to an exception that was *already caught*, not to an exception that was freshly raised. To clear the exception state, pass `NULL`.

### Note

This function is not normally used by code that wants to handle exceptions. Rather, it can be used when code needs to save and restore the exception state temporarily. Use `PyErr_GetHandledException()` to get the exception state.

*New in version 3.11.*

```
void PyErr_GetExcInfo(PyObject **ptype, PyObject **pvalue,  
PyObject **ptraceback)
```

Part of the *Stable ABI* since version 3.7.

Retrieve the old-style representation of the exception info, as known from `sys.exc_info()`. This refers to an exception that was *already caught*, not to an exception that was freshly raised. Returns new references for the three objects, any of which may be `NULL`. Does not modify the exception info state. This function is kept for backwards compatibility. Prefer using `PyErr_GetHandledException()`.

### Note

This function is not normally used by code that wants to handle exceptions. Rather, it can be used when code needs to save and restore the exception state temporarily. Use `PyErr_SetExcInfo()` to restore or clear the exception state.

*New in version 3.3.*

```
void PyErr_SetExcInfo(PyObject *type, PyObject *value, PyObject
```

\*`traceback`)

*Part of the [Stable ABI](#) since version 3.7.*

Set the exception info, as known from `sys.exc_info()`. This refers to an exception that was *already caught*, not to an exception that was freshly raised. This function steals the references of the arguments. To clear the exception state, pass `NULL` for all three arguments. This function is kept for backwards compatibility. Prefer using [`PyErr\_SetHandledException\(\)`](#).

### Note

This function is not normally used by code that wants to handle exceptions. Rather, it can be used when code needs to save and restore the exception state temporarily. Use [`PyErr\_GetExcInfo\(\)`](#) to read the exception state.

*New in version 3.3.*

*Changed in version 3.11:* The `type` and `traceback` arguments are no longer used and can be `NULL`. The interpreter now derives them from the exception instance (the `value` argument). The function still steals references of all three arguments.

## Signal Handling

`int PyErr_CheckSignals()`

*Part of the [Stable ABI](#).*

This function interacts with Python's signal handling.

If the function is called from the main thread and under the main Python interpreter, it checks whether a signal has been sent to the processes and if so, invokes the corresponding signal handler. If the [`signal`](#) module is supported, this can invoke a signal handler written in Python.

The function attempts to handle all pending signals, and then returns `0`. However, if a Python signal handler raises an

exception, the error indicator is set and the function returns `-1` immediately (such that other pending signals may not have been handled yet: they will be on the next `PyErr_CheckSignals()` invocation).

If the function is called from a non-main thread, or under a non-main Python interpreter, it does nothing and returns `0`.

This function can be called by long-running C code that wants to be interruptible by user requests (such as by pressing Ctrl-C).

### Note

The default Python signal handler for **SIGINT** raises the `KeyboardInterrupt` exception.

`void PyErr_SetInterrupt()`

*Part of the [Stable ABI](#).*

Simulate the effect of a **SIGINT** signal arriving. This is equivalent to `PyErr_SetInterruptEx(SIGINT)`.

### Note

This function is async-signal-safe. It can be called without the [GIL](#) and from a C signal handler.

`int PyErr_SetInterruptEx(int signum)`

*Part of the [Stable ABI](#) since version 3.10.*

Simulate the effect of a signal arriving. The next time `PyErr_CheckSignals()` is called, the Python signal handler for the given signal number will be called.

This function can be called by C code that sets up its own signal handling and wants Python signal handlers to be invoked as expected when an interruption is requested (for example when the user presses Ctrl-C to interrupt an

operation).

If the given signal isn't handled by Python (it was set to `signal.SIG_DFL` or `signal.SIG_IGN`), it will be ignored.

If *signum* is outside of the allowed range of signal numbers, `-1` is returned. Otherwise, `0` is returned. The error indicator is never changed by this function.

### Note

This function is async-signal-safe. It can be called without the `GIL` and from a C signal handler.

*New in version 3.10.*

`int PySignal_SetWakeupFd(int fd)`

This utility function specifies a file descriptor to which the signal number is written as a single byte whenever a signal is received. *fd* must be non-blocking. It returns the previous such file descriptor.

The value `-1` disables the feature; this is the initial state. This is equivalent to `signal.set_wakeup_fd()` in Python, but without any error checking. *fd* should be a valid file descriptor. The function should only be called from the main thread.

*Changed in version 3.5:* On Windows, the function now also supports socket handles.

## Exception Classes

`PyObject *PyErr_NewException(const char *name, PyObject *base, PyObject *dict)`

*Return value:* New reference. Part of the [Stable ABI](#).

This utility function creates and returns a new exception class. The *name* argument must be the name of the new exception, a C string of the form `module.classname`. The

*base* and *dict* arguments are normally `NULL`. This creates a class object derived from `Exception` (accessible in C as `PyExc_Exception`).

The `__module__` attribute of the new class is set to the first part (up to the last dot) of the *name* argument, and the class name is set to the last part (after the last dot). The *base* argument can be used to specify alternate base classes; it can either be only one class or a tuple of classes. The *dict* argument can be used to specify a dictionary of class variables and methods.

`PyObject *PyErr_NewExceptionWithDoc(const char *name, const char *doc, PyObject *base, PyObject *dict)`

*Return value:* New reference. Part of the [Stable ABI](#).

Same as `PyErr_NewException()`, except that the new exception class can easily be given a docstring: If *doc* is non-`NULL`, it will be used as the docstring for the exception class.

*New in version 3.2.*

## Exception Objects

`PyObject *PyException_GetTraceback(PyObject *ex)`

*Return value:* New reference. Part of the [Stable ABI](#).

Return the traceback associated with the exception as a new reference, as accessible from Python through `__traceback__`. If there is no traceback associated, this returns `NULL`.

`int PyException_SetTraceback(PyObject *ex, PyObject *tb)`

*Part of the [Stable ABI](#).*

Set the traceback associated with the exception to *tb*. Use `Py_None` to clear it.

`PyObject *PyException_GetContext(PyObject *ex)`

*Return value:* New reference. Part of the [Stable ABI](#).

Return the context (another exception instance during whose handling *ex* was raised) associated with the exception as a new reference, as accessible from Python through `__context__`. If there is no context associated, this returns `NULL`.

`void PyException_SetContext(PyObject *ex, PyObject *ctx)`

*Part of the [Stable ABI](#).*

Set the context associated with the exception to *ctx*. Use `NULL` to clear it. There is no type check to make sure that *ctx* is an exception instance. This steals a reference to *ctx*.

`PyObject *PyException_GetCause(PyObject *ex)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return the cause (either an exception instance, or `None`, set by `raise ... from ...`) associated with the exception as a new reference, as accessible from Python through `__cause__`.

`void PyException_SetCause(PyObject *ex, PyObject *cause)`

*Part of the [Stable ABI](#).*

Set the cause associated with the exception to *cause*. Use `NULL` to clear it. There is no type check to make sure that *cause* is either an exception instance or `None`. This steals a reference to *cause*.

`__suppress_context__` is implicitly set to `True` by this function.

`PyObject *PyException_GetArgs(PyObject *ex)`

*Return value: New reference. Part of the [Stable ABI](#) since version 3.12.*

Return `args` of exception *ex*.

`void PyException_SetArgs(PyObject *ex, PyObject *args)`

*Part of the [Stable ABI](#) since version 3.12.*

Set `args` of exception *ex* to *args*.

`PyObject *PyUnstable_Exc_PrepReraiseStar(PyObject *orig,  
PyObject *excs)`

*This is **Unstable API**. It may change without warning in minor releases.*

Implement part of the interpreter's implementation of **except\***. *orig* is the original exception that was caught, and *excs* is the list of the exceptions that need to be raised. This list contains the unhandled part of *orig*, if any, as well as the exceptions that were raised from the **except\*** clauses (so they have a different traceback from *orig*) and those that were reraised (and have the same traceback as *orig*). Return the **ExceptionGroup** that needs to be reraised in the end, or `None` if there is nothing to reraise.

*New in version 3.12.*

## Unicode Exception Objects

The following functions are used to create and modify Unicode exceptions from C.

`PyObject *PyUnicodeDecodeError_Create(const char *encoding,  
const char *object, Py_ssize_t length, Py_ssize_t start, Py_ssize_t end,  
const char *reason)`

*Return value: New reference. Part of the **Stable ABI**.*

Create a **UnicodeDecodeError** object with the attributes *encoding*, *object*, *length*, *start*, *end* and *reason*. *encoding* and *reason* are UTF-8 encoded strings.

`PyObject *PyUnicodeDecodeError_GetEncoding(PyObject *exc)  
PyObject *PyUnicodeEncodeError_GetEncoding(PyObject *exc)`

*Return value: New reference. Part of the **Stable ABI**.*

Return the *encoding* attribute of the given exception object.

`PyObject *PyUnicodeDecodeError_GetObject(PyObject *exc)`

`PyObject *`PyUnicodeEncodeError\_GetObject(`PyObject *exc`)  
`PyObject *`PyUnicodeTranslateError\_GetObject(`PyObject *exc`)

*Return value: New reference. Part of the [Stable ABI](#).*

Return the *object* attribute of the given exception object.

`int` PyUnicodeDecodeError\_GetStart(`PyObject *exc`, `Py_ssize_t *start`)

`int` PyUnicodeEncodeError\_GetStart(`PyObject *exc`, `Py_ssize_t *start`)

`int` PyUnicodeTranslateError\_GetStart(`PyObject *exc`, `Py_ssize_t *start`)

*Part of the [Stable ABI](#).*

Get the *start* attribute of the given exception object and place it into *\*start*. *start* must not be `NULL`. Return `0` on success, `-1` on failure.

`int` PyUnicodeDecodeError\_SetStart(`PyObject *exc`, `Py_ssize_t start`)

`int` PyUnicodeEncodeError\_SetStart(`PyObject *exc`, `Py_ssize_t start`)

`int` PyUnicodeTranslateError\_SetStart(`PyObject *exc`, `Py_ssize_t start`)

*Part of the [Stable ABI](#).*

Set the *start* attribute of the given exception object to *start*. Return `0` on success, `-1` on failure.

`int` PyUnicodeDecodeError\_GetEnd(`PyObject *exc`, `Py_ssize_t *end`)

`int` PyUnicodeEncodeError\_GetEnd(`PyObject *exc`, `Py_ssize_t *end`)

`int` PyUnicodeTranslateError\_GetEnd(`PyObject *exc`, `Py_ssize_t *end`)

*Part of the [Stable ABI](#).*

Get the *end* attribute of the given exception object and place it into *\*end*. *end* must not be `NULL`. Return `0` on success, `-1` on failure.

`int` PyUnicodeDecodeError\_SetEnd(`PyObject *exc`, `Py_ssize_t end`)

`int` PyUnicodeEncodeError\_SetEnd(`PyObject *exc`, `Py_ssize_t end`)

int PyUnicodeTranslateError\_SetEnd(PyObject \*exc, Py\_ssize\_t end)

*Part of the [Stable ABI](#).*

Set the *end* attribute of the given exception object to *end*.

Return 0 on success, -1 on failure.

PyObject \*PyUnicodeDecodeError\_GetReason(PyObject \*exc)

PyObject \*PyUnicodeEncodeError\_GetReason(PyObject \*exc)

PyObject \*PyUnicodeTranslateError\_GetReason(PyObject \*exc)

*Return value: New reference. Part of the [Stable ABI](#).*

Return the *reason* attribute of the given exception object.

int PyUnicodeDecodeError\_SetReason(PyObject \*exc, const char \*reason)

int PyUnicodeEncodeError\_SetReason(PyObject \*exc, const char \*reason)

int PyUnicodeTranslateError\_SetReason(PyObject \*exc, const char \*reason)

*Part of the [Stable ABI](#).*

Set the *reason* attribute of the given exception object to

*reason*. Return 0 on success, -1 on failure.

## Recursion Control

These two functions provide a way to perform safe recursive calls at the C level, both in the core and in extension modules. They are needed if the recursive code does not necessarily invoke Python code (which tracks its recursion depth automatically). They are also not needed for *tp\_call* implementations because the [call protocol](#) takes care of recursion handling.

int Py\_EnterRecursiveCall(const char \*where)

*Part of the [Stable ABI](#) since version 3.9.*

Marks a point where a recursive C-level call is about to be performed.

If **USE\_STACKCHECK** is defined, this function checks if the

OS stack overflowed using `PyOS_CheckStack()`. In this is the case, it sets a `MemoryError` and returns a nonzero value.

The function then checks if the recursion limit is reached. If this is the case, a `RecursionError` is set and a nonzero value is returned. Otherwise, zero is returned.

*where* should be a UTF-8 encoded string such as `" in instance check"` to be concatenated to the `RecursionError` message caused by the recursion depth limit.

*Changed in version 3.9:* This function is now also available in the [limited API](#).

`void Py_LeaveRecursiveCall(void)`

*Part of the [Stable ABI](#) since version 3.9.*

Ends a `Py_EnterRecursiveCall()`. Must be called once for each *successful* invocation of `Py_EnterRecursiveCall()`.

*Changed in version 3.9:* This function is now also available in the [limited API](#).

Properly implementing `tp_repr` for container types requires special recursion handling. In addition to protecting the stack, `tp_repr` also needs to track objects to prevent cycles. The following two functions facilitate this functionality. Effectively, these are the C equivalent to `reprlib.recursive_repr()`.

`int Py_ReprEnter(PyObject *object)`

*Part of the [Stable ABI](#).*

Called at the beginning of the `tp_repr` implementation to detect cycles.

If the object has already been processed, the function returns a positive integer. In that case the `tp_repr` implementation should return a string object indicating a cycle. As examples, `dict` objects return `{ ... }` and `list` objects return

[...].

The function will return a negative integer if the recursion limit is reached. In that case the `tp_repr` implementation should typically return `NULL`.

Otherwise, the function returns zero and the `tp_repr` implementation can continue normally.

void Py\_ReprLeave(PyObject \*object)

Part of the *Stable ABI*.

Ends a `Py_ReprEnter()`. Must be called once for each invocation of `Py_ReprEnter()` that returns zero.

## Standard Exceptions

All standard Python exceptions are available as global variables whose names are `PyExc_` followed by the Python exception name. These have the type `PyObject*`; they are all class objects. For completeness, here are all the variables:

**PyNameName**

---

`PyExc_BaseException`

---

`PyExc_Exception`

---

`PyExc_ArithmeticError`

---

`PyExc_AssertionError`

---

`PyExc_AttributeError`

---

`PyExc_BlockingIOError`

---

`PyExc_BrokenPipeError`

---

`PyExc_BufferError`

---

`PyExc_ChildProcessError`

---

`PyExc_ConnectionAbortedError`

---

`PyExc_ConnectionError`

---

`PyExc_ConnectionRefusedError`

---

`PyExc_ConnectionResetError`

---

`PyExc_EOFError`

---

`PyExc_FileExistsError`

---

`PyExc FileNotFoundError`

---

`PyExc_KeyboardInterrupt`

---

<code>PyExc_GeneratorExit</code>
<code>PyExc_ImportError</code>
<code>PyExc_IndentationError</code>
<code>PyExc_IndexError</code>
<code>PyExc_InterruptedError</code>
<code>PyExc_IsADirectoryError</code>
<code>PyExc_KeyError</code>
<code>PyExc_KeyboardInterrupt</code>
<code>PyExc LookupError</code>
<code>PyExc_MemoryError</code>
<code>PyExc_ModifiedError</code>
<code>PyExc_NameError</code>
<code>PyExc_NetADirectoryError</code>
<code>PyExc_NotImplementedError</code>
<code>PyExc_OSError</code>
<code>PyExc_OSError</code>
<code>PyExc_PermissionError</code>
<code>PyExc_BlockingIOError</code>
<code>PyExc_RestoreError</code>
<code>PyExc_ReferenceError</code>
<code>PyExc_RuntimeError</code>
<code>PyExc_StopAsyncIteration</code>
<code>PyExc_StopIteration</code>
<code>PyExc_SyntaxError</code>
<code>PyExc_SystemError</code>
<code>PyExc_SystemExit</code>
<code>PyExc_TabError</code>
<code>PyExc_TimeoutError</code>
<code>PyExc_TypeError</code>
<code>PyExc_UnboundLocalError</code>
<code>PyExc_UnASCIIcodeDecodeError</code>
<code>PyExc_UnASCIIcodeEncodeError</code>
<code>PyExc_UniCodeError</code>
<code>PyExc_UniCodeTranslateError</code>
<code>PyExc_ValueError</code>
<code>PyExc_ZeroDivisionError</code>

New in version 3.3: `PyExc_BlockingIOError`,  
`PyExc_BrokenPipeError`, `PyExc_ChildProcessError`,  
`PyExc_ConnectionError`,

**PyExc\_ConnectionAbortedError**,  
**PyExc\_ConnectionRefusedError**,  
**PyExc\_ConnectionResetError**, **PyExc\_FileExistsError**,  
**PyExc\_FileNotFoundError**, **PyExc\_InterruptedError**,  
**PyExc\_IsADirectoryError**, **PyExc\_NotADirectoryError**,  
**PyExc\_PermissionError**, **PyExc\_ProcessLookupError** and  
**PyExc\_TimeoutError** were introduced following [PEP 3151](https://peps.python.org/pep-3151/)  
[<https://peps.python.org/pep-3151/>].

*New in version 3.5:* **PyExc\_StopAsyncIteration** and  
**PyExc\_RecursionError**.

*New in version 3.6:* **PyExc\_ModuleNotFoundError**.

These are compatibility aliases to **PyExc\_OSError**:

<b>Name</b>
<b>PyExc_EnvironmentError</b>
<b>PyExc_IOError</b>
<b>PyExc_WindowsError</b>

*Changed in version 3.3:* These aliases used to be separate exception types.

Notes:

1([1](#),[2](#),[3](#),[4](#),[5](#))

This is a base class for other standard exceptions.

[2](#)

Only defined on Windows; protect code that uses this by testing that the preprocessor macro `MS_WINDOWS` is defined.

## Standard Warning Categories

All standard Python warning categories are available as global variables whose names are `PyExc_` followed by the Python exception name. These have the type [PyObject\\*](#); they are all class objects. For completeness, here are all the variables:

Warning Name
<code>PyExc_Warning</code>
<code>PyExc_WarningsWarning</code>
<code>PyExc_DeprecationWarning</code>
<code>PyExc_FutureWarning</code>
<code>PyExc_ImportWarning</code>
<code>PyExc_PendingDeprecationWarning</code>
<code>PyExc_ResourceWarning</code>
<code>PyExc_SyntaxWarning</code>
<code>PyExc_UnicodeWarning</code>
<code>PyExc_UserWarning</code>

New in version 3.2: `PyExc_ResourceWarning`.

Notes:

3

This is a base class for other standard warning categories.

# Utilities

The functions in this chapter perform various utility tasks, ranging from helping C code be more portable across platforms, using Python modules from C, and parsing function arguments and constructing Python values from C values.

# Operating System Utilities

`PyObject *PyOS_FSPath(PyObject *path)`

*Return value:* New reference. Part of the [Stable ABI](#) since version 3.6.

Return the file system representation for *path*. If the object is a `str` or `bytes` object, then a new [strong reference](#) is returned. If the object implements the `os.PathLike` interface, then `__fspath__()` is returned as long as it is a `str` or `bytes` object. Otherwise `TypeError` is raised and `NULL` is returned.

*New in version 3.6.*

`int Py_FdIsInteractive(FILE *fp, const char *filename)`

Return true (nonzero) if the standard I/O file *fp* with name *filename* is deemed interactive. This is the case for files for which `isatty(fileno(fp))` is true. If the [PyConfig.interactive](#) is non-zero, this function also returns true if the *filename* pointer is `NULL` or if the name is equal to one of the strings `'<stdin>'` or `'???'`.

This function must not be called before Python is initialized.

`void PyOS_BeforeFork()`

*Part of the [Stable ABI](#) on platforms with `fork()` since version 3.7.* Function to prepare some internal state before a process fork. This should be called before calling `fork()` or any similar function that clones the current process. Only available on systems where `fork()` is defined.

## Warning

The C `fork()` call should only be made from the “[main](#)” [thread](#) (of the “[main](#)” [interpreter](#)). The same is true for

`PyOS_BeforeFork()`.

*New in version 3.7.*

`void PyOS_AfterFork_Parent()`

Part of the [Stable ABI](#) on platforms with `fork()` since version 3.7. Function to update some internal state after a process fork. This should be called from the parent process after calling **`fork()`** or any similar function that clones the current process, regardless of whether process cloning was successful. Only available on systems where **`fork()`** is defined.

### Warning

The C **`fork()`** call should only be made from the “[main](#)” [thread](#) (of the “[main](#)” [interpreter](#)). The same is true for `PyOS_AfterFork_Parent()`.

*New in version 3.7.*

`void PyOS_AfterFork_Child()`

Part of the [Stable ABI](#) on platforms with `fork()` since version 3.7. Function to update internal interpreter state after a process fork. This must be called from the child process after calling **`fork()`**, or any similar function that clones the current process, if there is any chance the process will call back into the Python interpreter. Only available on systems where **`fork()`** is defined.

### Warning

The C **`fork()`** call should only be made from the “[main](#)” [thread](#) (of the “[main](#)” [interpreter](#)). The same is true for `PyOS_AfterFork_Child()`.

*New in version 3.7.*

**See also**

`os.register_at_fork()` allows registering custom Python functions to be called by `PyOS_BeforeFork()`, `PyOS_AfterFork_Parent()` and `PyOS_AfterFork_Child()`.

`void PyOS_AfterFork()`

*Part of the [Stable ABI](#) on platforms with `fork()`.*

Function to update some internal state after a process fork; this should be called in the new process if the Python interpreter will continue to be used. If a new executable is loaded into the new process, this function does not need to be called.

*Deprecated since version 3.7:* This function is superseded by `PyOS_AfterFork_Child()`.

`int PyOS_CheckStack()`

*Part of the [Stable ABI](#) on platforms with `USE_STACKCHECK` since version 3.7.*

Return true when the interpreter runs out of stack space. This is a reliable check, but is only available when **USE\_STACKCHECK** is defined (currently on certain versions of Windows using the Microsoft Visual C++ compiler). **USE\_STACKCHECK** will be defined automatically; you should never change the definition in your own code.

`PyOS_sighandler_t PyOS_getsig(int i)`

*Part of the [Stable ABI](#).*

Return the current signal handler for signal *i*. This is a thin wrapper around either `sigaction()` or `signal()`. Do not call those functions directly! `PyOS_sighandler_t` is a typedef alias for `void (*)(int)`.

`PyOS_sighandler_t PyOS_setsig(int i, PyOS_sighandler_t h)`

*Part of the [Stable ABI](#).*

Set the signal handler for signal *i* to be *h*; return the old signal handler. This is a thin wrapper around either `sigaction()`

or `signal()`. Do not call those functions directly!  
`PyOS_sighandler_t` is a typedef alias for `void (*)(int)`.

`wchar_t *Py_DecodeLocale(const char *arg, size_t *size)`

Part of the *Stable ABI* since version 3.7.

### Warning

This function should not be called directly: use the `PyConfig` API with the `PyConfig_SetBytesString()` function which ensures that *Python is preinitialized*.

This function must not be called before *Python is preinitialized* and so that the `LC_CTYPE` locale is properly configured: see the `Py_PreInitialize()` function.

Decode a byte string from the *filesystem encoding and error handler*. If the error handler is *surrogateescape error handler*, undecodable bytes are decoded as characters in range `U + DC80..U + DCFF`; and if a byte sequence can be decoded as a surrogate character, the bytes are escaped using the *surrogateescape error handler* instead of decoding them.

Return a pointer to a newly allocated wide character string, use `PyMem_RawFree()` to free the memory. If `size` is not `NULL`, write the number of wide characters excluding the null character into `*size`

Return `NULL` on decoding error or memory allocation error. If `size` is not `NULL`, `*size` is set to `(size_t)-1` on memory error or set to `(size_t)-2` on decoding error.

The *filesystem encoding and error handler* are selected by `PyConfig_Read()`: see *filesystem\_encoding* and *filesystem\_errors* members of `PyConfig`.

Decoding errors should never happen, unless there is a bug in the C library.

Use the `Py_EncodeLocale()` function to encode the

character string back to a byte string.

### See also

The [PyUnicode\\_DecodeFSDefaultAndSize\(\)](#) and [PyUnicode\\_DecodeLocaleAndSize\(\)](#) functions.

*New in version 3.5.*

*Changed in version 3.7:* The function now uses the UTF-8 encoding in the [Python UTF-8 Mode](#).

*Changed in version 3.8:* The function now uses the UTF-8 encoding on Windows if [PyPreConfig.legacy\\_windows\\_fs\\_encoding](#) is zero;

char \*Py\_EncodeLocale(const wchar\_t \*text, size\_t \*error\_pos)

*Part of the [Stable ABI](#) since version 3.7.*

Encode a wide character string to the [filesystem encoding and error handler](#). If the error handler is [surrogateescape error handler](#), surrogate characters in the range U + DC80..U + DCFF are converted to bytes 0x80..0xFF.

Return a pointer to a newly allocated byte string, use [PyMem\\_Free\(\)](#) to free the memory. Return `NULL` on encoding error or memory allocation error.

If `error_pos` is not `NULL`, `*error_pos` is set to `(size_t)-1` on success, or set to the index of the invalid character on encoding error.

The [filesystem encoding and error handler](#) are selected by [PyConfig\\_Read\(\)](#): see [filesystem\\_encoding](#) and [filesystem\\_errors](#) members of [PyConfig](#).

Use the [Py\\_DecodeLocale\(\)](#) function to decode the bytes string back to a wide character string.

### Warning

This function must not be called before [Python is](#)

`preinitialized` and so that the `LC_CTYPE` locale is properly configured: see the `Py_PreInitialize()` function.

### See also

The `PyUnicode_EncodeFSDefault()` and `PyUnicode_EncodeLocale()` functions.

*New in version 3.5.*

*Changed in version 3.7:* The function now uses the UTF-8 encoding in the [Python UTF-8 Mode](#).

*Changed in version 3.8:* The function now uses the UTF-8 encoding on Windows if `PyPreConfig.legacy_windows_fs_encoding` is zero.

## System Functions

These are utility functions that make functionality from the `sys` module accessible to C code. They all work with the current interpreter thread's `sys` module's dict, which is contained in the internal thread state structure.

`PyObject *``PySys_GetObject`(const char \*name)

*Return value:* Borrowed reference. Part of the [Stable ABI](#).

Return the object *name* from the `sys` module or `NULL` if it does not exist, without setting an exception.

int `PySys_SetObject`(const char \*name, `PyObject *`v)

*Part of the [Stable ABI](#).*

Set *name* in the `sys` module to *v* unless *v* is `NULL`, in which case *name* is deleted from the `sys` module. Returns 0 on success, -1 on error.

`void PySys_ResetWarnOptions()`

*Part of the [Stable ABI](#).*

Reset `sys.warnoptions` to an empty list. This function may be called prior to `Py_Initialize()`.

`void PySys_AddWarnOption(const wchar_t *s)`

*Part of the [Stable ABI](#).*

This API is kept for backward compatibility: setting `PyConfig.warnoptions` should be used instead, see [Python Initialization Configuration](#).

Append `s` to `sys.warnoptions`. This function must be called prior to `Py_Initialize()` in order to affect the warnings filter list.

*Deprecated since version 3.11.*

`void PySys_AddWarnOptionUnicode(PyObject *unicode)`

*Part of the [Stable ABI](#).*

This API is kept for backward compatibility: setting `PyConfig.warnoptions` should be used instead, see [Python Initialization Configuration](#).

Append `unicode` to `sys.warnoptions`.

Note: this function is not currently usable from outside the CPython implementation, as it must be called prior to the implicit import of `warnings` in `Py_Initialize()` to be effective, but can't be called until enough of the runtime has been initialized to permit the creation of Unicode objects.

*Deprecated since version 3.11.*

`void PySys_SetPath(const wchar_t *path)`

*Part of the [Stable ABI](#).*

This API is kept for backward compatibility: setting `PyConfig.module_search_paths` and `PyConfig.module_search_paths_set` should be used instead, see [Python Initialization Configuration](#).

Set `sys.path` to a list object of paths found in `path` which should be a list of paths separated with the platform's search path delimiter (: on Unix, ; on Windows).

*Deprecated since version 3.11.*

`void PySys_WriteStdout(const char *format, ...)`

*Part of the [Stable ABI](#).*

Write the output string described by *format* to `sys.stdout`. No exceptions are raised, even if truncation occurs (see below).

*format* should limit the total size of the formatted output string to 1000 bytes or less – after 1000 bytes, the output string is truncated. In particular, this means that no unrestricted “%s” formats should occur; these should be limited using “%.<N>s” where <N> is a decimal number calculated so that <N> plus the maximum size of other formatted text does not exceed 1000 bytes. Also watch out for “%f”, which can print hundreds of digits for very large numbers.

If a problem occurs, or `sys.stdout` is unset, the formatted message is written to the real (C level) *stdout*.

`void PySys_WriteStderr(const char *format, ...)`

*Part of the [Stable ABI](#).*

As `PySys_WriteStdout()`, but write to `sys.stderr` or *stderr* instead.

`void PySys_FormatStdout(const char *format, ...)`

*Part of the [Stable ABI](#).*

Function similar to `PySys_WriteStdout()` but format the message using `PyUnicode_FromFormatV()` and don't truncate the message to an arbitrary length.

*New in version 3.2.*

`void PySys_FormatStderr(const char *format, ...)`

Part of the *Stable ABI*.

As `PySys_FormatStdout()`, but write to `sys.stderr` or `stderr` instead.

*New in version 3.2.*

`void PySys_AddXOption(const wchar_t *s)`

Part of the *Stable ABI* since version 3.7.

This API is kept for backward compatibility: setting `PyConfig.xoptions` should be used instead, see [Python Initialization Configuration](#).

Parse `s` as a set of `-X` options and add them to the current options mapping as returned by `PySys_GetXOptions()`. This function may be called prior to `Py_Initialize()`.

*New in version 3.2.*

*Deprecated since version 3.11.*

`PyObject *PySys_GetXOptions()`

Return value: Borrowed reference. Part of the *Stable ABI* since version 3.7.

Return the current dictionary of `-X` options, similarly to `sys._xoptions`. On error, `NULL` is returned and an exception is set.

*New in version 3.2.*

`int PySys_Audit(const char *event, const char *format, ...)`

Raise an auditing event with any active hooks. Return zero for success and non-zero with an exception set on failure.

If any hooks have been added, `format` and other arguments will be used to construct a tuple to pass. Apart from `N`, the same format characters as used in `Py_BuildValue()` are available. If the built value is not a tuple, it will be added into a single-element tuple. (The `N` format option consumes a reference, but since there is no way to know whether

arguments to this function will be consumed, using it may cause reference leaks.)

Note that `#` format characters should always be treated as `Py_ssize_t`, regardless of whether `PY_SSIZE_T_CLEAN` was defined.

`sys.audit()` performs the same function from Python code.

*New in version 3.8.*

*Changed in version 3.8.2:* Require `Py_ssize_t` for `#` format characters. Previously, an unavoidable deprecation warning was raised.

```
int PySys_AddAuditHook(Py_AuditHookFunction hook, void
*userData)
```

Append the callable *hook* to the list of active auditing hooks. Return zero on success and non-zero on failure. If the runtime has been initialized, also set an error on failure. Hooks added through this API are called for all interpreters created by the runtime.

The *userData* pointer is passed into the hook function. Since hook functions may be called from different runtimes, this pointer should not refer directly to Python state.

This function is safe to call before `Py_Initialize()`. When called after runtime initialization, existing audit hooks are notified and may silently abort the operation by raising an error subclassed from `Exception` (other errors will not be silenced).

The hook function is of type `int (*)(const char *event, PyObject *args, void *userData)`, where *args* is guaranteed to be a `PyTupleObject`. The hook function is always called with the GIL held by the Python interpreter that raised the event.

See [PEP 578](https://peps.python.org/pep-0578/) [https://peps.python.org/pep-0578/] for a detailed description of auditing. Functions in the runtime and

standard library that raise events are listed in the [audit events table](#). Details are in each function's documentation.

If the interpreter is initialized, this function raises a auditing event `sys.addaudithook` with no arguments. If any existing hooks raise an exception derived from [Exception](#), the new hook will not be added and the exception is cleared. As a result, callers cannot assume that their hook has been added unless they control all existing hooks.

*New in version 3.8.*

## Process Control

`void Py_FatalError(const char *message)`

*Part of the [Stable ABI](#).*

Print a fatal error message and kill the process. No cleanup is performed. This function should only be invoked when a condition is detected that would make it dangerous to continue using the Python interpreter; e.g., when the object administration appears to be corrupted. On Unix, the standard C library function `abort()` is called which will attempt to produce a `core` file.

The `Py_FatalError()` function is replaced with a macro which logs automatically the name of the current function, unless the `Py_LIMITED_API` macro is defined.

*Changed in version 3.9:* Log the function name automatically.

`void Py_Exit(int status)`

*Part of the [Stable ABI](#).*

Exit the current process. This calls `Py_FinalizeEx()` and then calls the standard C library function `exit(status)`. If `Py_FinalizeEx()` indicates an error, the exit status is set to 120.

*Changed in version 3.6:* Errors from finalization no longer ignored.

`int Py_AtExit(void (*func)())`

*Part of the [Stable ABI](#).*

Register a cleanup function to be called by `Py_FinalizeEx()`. The cleanup function will be called with no arguments and should return no value. At most 32 cleanup functions can be registered. When the registration is successful, `Py_AtExit()` returns 0; on failure, it returns -1. The cleanup function registered last is called first. Each cleanup function will be called at most once. Since Python's internal finalization will have completed before the cleanup function, no Python APIs should be called by *func*.

# Importing Modules

**PyObject \***PyImport\_ImportModule(const char \*name)

*Return value:* New reference. Part of the [Stable ABI](#).

This is a simplified interface to

**PyImport\_ImportModuleEx()** below, leaving the *globals* and *locals* arguments set to `NULL` and *level* set to 0. When the *name* argument contains a dot (when it specifies a submodule of a package), the *fromlist* argument is set to the list `['*']` so that the return value is the named module rather than the top-level package containing it as would otherwise be the case. (Unfortunately, this has an additional side effect when *name* in fact specifies a subpackage instead of a submodule: the submodules specified in the package's `__all__` variable are loaded.) Return a new reference to the imported module, or `NULL` with an exception set on failure. A failing import of a module doesn't leave the module in `sys.modules`.

This function always uses absolute imports.

**PyObject \***PyImport\_ImportModuleNoBlock(const char \*name)

*Return value:* New reference. Part of the [Stable ABI](#).

This function is a deprecated alias of

**PyImport\_ImportModule()**.

*Changed in version 3.3:* This function used to fail immediately when the import lock was held by another thread. In Python 3.3 though, the locking scheme switched to per-module locks for most purposes, so this function's special behaviour isn't needed anymore.

**PyObject \***PyImport\_ImportModuleEx(const char \*name, **PyObject** \*globals, **PyObject** \*locals, **PyObject** \*fromlist)

*Return value:* New reference.

Import a module. This is best described by referring to the built-in Python function `__import__()`.

The return value is a new reference to the imported module or top-level package, or `NULL` with an exception set on failure. Like for `__import__()`, the return value when a submodule of a package was requested is normally the top-level package, unless a non-empty *fromlist* was given.

Failing imports remove incomplete module objects, like with `PyImport_ImportModule()`.

`PyObject *PyImport_ImportModuleLevelObject(PyObject *name, PyObject *globals, PyObject *locals, PyObject *fromlist, int level)`

*Return value:* New reference. Part of the *Stable ABI* since version 3.7.

Import a module. This is best described by referring to the built-in Python function `__import__()`, as the standard `__import__()` function calls this function directly.

The return value is a new reference to the imported module or top-level package, or `NULL` with an exception set on failure. Like for `__import__()`, the return value when a submodule of a package was requested is normally the top-level package, unless a non-empty *fromlist* was given.

*New in version 3.3.*

`PyObject *PyImport_ImportModuleLevel(const char *name, PyObject *globals, PyObject *locals, PyObject *fromlist, int level)`

*Return value:* New reference. Part of the *Stable ABI*.

Similar to `PyImport_ImportModuleLevelObject()`, but the name is a UTF-8 encoded string instead of a Unicode object.

*Changed in version 3.3:* Negative values for *level* are no longer accepted.

`PyObject *PyImport_Import(PyObject *name)`

*Return value: New reference. Part of the [Stable ABI](#).*

This is a higher-level interface that calls the current “import hook function” (with an explicit *level* of 0, meaning absolute import). It invokes the `__import__()` function from the `__builtins__` of the current globals. This means that the import is done using whatever import hooks are installed in the current environment.

This function always uses absolute imports.

`PyObject *``PyImport_ReloadModule(PyObject *m)`

*Return value: New reference. Part of the [Stable ABI](#).*

Reload a module. Return a new reference to the reloaded module, or `NULL` with an exception set on failure (the module still exists in this case).

`PyObject *``PyImport_AddModuleObject(PyObject *name)`

*Return value: Borrowed reference. Part of the [Stable ABI](#) since version 3.7.*

Return the module object corresponding to a module name. The *name* argument may be of the form `package.module`. First check the modules dictionary if there’s one there, and if not, create a new one and insert it in the modules dictionary. Return `NULL` with an exception set on failure.

### Note

This function does not load or import the module; if the module wasn’t already loaded, you will get an empty module object. Use `PyImport_ImportModule()` or one of its variants to import a module. Package structures implied by a dotted name for *name* are not created if not already present.

*New in version 3.3.*

`PyObject *``PyImport_AddModule(const char *name)`

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Similar to `PyImport_AddModuleObject()`, but the name is a UTF-8 encoded string instead of a Unicode object.

`PyObject *PyImport_ExecCodeModule(const char *name, PyObject *co)`

*Return value:* New reference. Part of the [Stable ABI](#).

Given a module name (possibly of the form `package.module`) and a code object read from a Python bytecode file or obtained from the built-in function `compile()`, load the module. Return a new reference to the module object, or `NULL` with an exception set if an error occurred. `name` is removed from `sys.modules` in error cases, even if `name` was already in `sys.modules` on entry to `PyImport_ExecCodeModule()`. Leaving incompletely initialized modules in `sys.modules` is dangerous, as imports of such modules have no way to know that the module object is an unknown (and probably damaged with respect to the module author's intents) state.

The module's `__spec__` and `__loader__` will be set, if not set already, with the appropriate values. The spec's loader will be set to the module's `__loader__` (if set) and to an instance of `SourceFileLoader` otherwise.

The module's `__file__` attribute will be set to the code object's `co_filename`. If applicable, `__cached__` will also be set.

This function will reload the module if it was already imported. See `PyImport_ReloadModule()` for the intended way to reload a module.

If `name` points to a dotted name of the form `package.module`, any package structures not already created will still not be created.

See also `PyImport_ExecCodeModuleEx()` and `PyImport_ExecCodeModuleWithPathnames()`.

*Changed in version 3.12:* The setting of `__cached__` and

`__loader__` is deprecated. See `ModuleSpec` for alternatives.

`PyObject *``PyImport_ExecCodeModuleEx`(const char \*name,  
`PyObject *`co, const char \*pathname)

*Return value:* New reference. Part of the *Stable ABI*.

Like `PyImport_ExecCodeModule()`, but the `__file__` attribute of the module object is set to *pathname* if it is non-NULL.

See also `PyImport_ExecCodeModuleWithPathnames()`.

`PyObject *``PyImport_ExecCodeModuleObject`(`PyObject *`name,  
`PyObject *`co, `PyObject *`pathname, `PyObject *`cpathname)

*Return value:* New reference. Part of the *Stable ABI* since version 3.7.

Like `PyImport_ExecCodeModuleEx()`, but the `__cached__` attribute of the module object is set to *cpathname* if it is non-NULL. Of the three functions, this is the preferred one to use.

*New in version 3.3.*

*Changed in version 3.12:* Setting `__cached__` is deprecated. See `ModuleSpec` for alternatives.

`PyObject *``PyImport_ExecCodeModuleWithPathnames`(const char \*name, `PyObject *`co, const char \*pathname, const char \*cpathname)

*Return value:* New reference. Part of the *Stable ABI*.

Like `PyImport_ExecCodeModuleObject()`, but *name*, *pathname* and *cpathname* are UTF-8 encoded strings. Attempts are also made to figure out what the value for *pathname* should be from *cpathname* if the former is set to NULL.

*New in version 3.2.*

*Changed in version 3.3:* Uses `imp.source_from_cache()`

in calculating the source path if only the bytecode path is provided.

*Changed in version 3.12:* No longer uses the removed `imp` module.

`long PyImport_GetMagicNumber()`

*Part of the [Stable ABI](#).*

Return the magic number for Python bytecode files (a.k.a. `.pyc` file). The magic number should be present in the first four bytes of the bytecode file, in little-endian byte order. Returns `-1` on error.

*Changed in version 3.3:* Return value of `-1` upon failure.

`const char *PyImport_GetMagicTag()`

*Part of the [Stable ABI](#).*

Return the magic tag string for [PEP 3147](#) [<https://peps.python.org/pep-3147/>] format Python bytecode file names. Keep in mind that the value at `sys.implementation.cache_tag` is authoritative and should be used instead of this function.

*New in version 3.2.*

[PyObject](#) \*PyImport\_GetModuleDict()

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Return the dictionary used for the module administration (a.k.a. `sys.modules`). Note that this is a per-interpreter variable.

[PyObject](#) \*PyImport\_GetModule([PyObject](#) \*name)

*Return value: New reference. Part of the [Stable ABI](#) since version 3.8.*

Return the already imported module with the given name. If the module has not been imported yet then returns `NULL` but does not set an error. Returns `NULL` and sets an error if the lookup failed.

*New in version 3.7.*

`PyObject *PyImport_GetImporter(PyObject *path)`

*Return value:* New reference. Part of the [Stable ABI](#).

Return a finder object for a `sys.path/pkg.__path__` item `path`, possibly by fetching it from the `sys.path_importer_cache` dict. If it wasn't yet cached, traverse `sys.path_hooks` until a hook is found that can handle the path item. Return `None` if no hook could; this tells our caller that the [path based finder](#) could not find a finder for this path item. Cache the result in `sys.path_importer_cache`. Return a new reference to the finder object.

`int PyImport_ImportFrozenModuleObject(PyObject *name)`

*Part of the [Stable ABI](#) since version 3.7.*

Load a frozen module named `name`. Return `1` for success, `0` if the module is not found, and `-1` with an exception set if the initialization failed. To access the imported module on a successful load, use `PyImport_ImportModule()`. (Note the misnomer — this function would reload the module if it was already imported.)

*New in version 3.3.*

*Changed in version 3.4:* The `__file__` attribute is no longer set on the module.

`int PyImport_ImportFrozenModule(const char *name)`

*Part of the [Stable ABI](#).*

Similar to `PyImport_ImportFrozenModuleObject()`, but the name is a UTF-8 encoded string instead of a Unicode object.

`struct _frozen`

This is the structure type definition for frozen module descriptors, as generated by the `freeze` utility (see `Tools/freeze/` in the Python source distribution). Its definition,

found in `Include/import.h`, is:

```
struct _frozen {
    const char *name;
    const unsigned char *code;
    int size;
    bool is_package;
};
```

*Changed in version 3.11:* The new `is_package` field indicates whether the module is a package or not. This replaces setting the `size` field to a negative value.

`const struct _frozen *PyImport_FrozenModules`

This pointer is initialized to point to an array of `_frozen` records, terminated by one whose members are all `NULL` or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

`int PyImport_AppendInittab(const char *name, PyObject  
*(*initfunc)(void))`

*Part of the [Stable ABI](#).*

Add a single module to the existing table of built-in modules. This is a convenience wrapper around

`PyImport_ExtendInittab()`, returning `-1` if the table could not be extended. The new module can be imported by the name *name*, and uses the function *initfunc* as the initialization function called on the first attempted import. This should be called before `Py_Initialize()`.

`struct _inittab`

Structure describing a single entry in the list of built-in modules. Programs which embed Python may use an array of these structures in conjunction with `PyImport_ExtendInittab()` to provide additional built-in modules. The structure consists of two members:

`const char *name`

The module name, as an ASCII encoded string.

`int PyImport_ExtendInittab(struct \_inittab *newtab)`

Add a collection of modules to the table of built-in modules. The *newtab* array must end with a sentinel entry which contains `NULL` for the [name](#) field; failure to provide the sentinel value can result in a memory fault. Returns `0` on success or `-1` if insufficient memory could be allocated to extend the internal table. In the event of failure, no modules are added to the internal table. This must be called before [Py\\_Initialize\(\)](#).

If Python is initialized multiple times, [PyImport\\_AppendInittab\(\)](#) or [PyImport\\_ExtendInittab\(\)](#) must be called before each Python initialization.

# Data marshalling support

These routines allow C code to work with serialized objects using the same data format as the `marshal` module. There are functions to write data into the serialization format, and additional functions that can be used to read the data back. Files used to store marshalled data must be opened in binary mode.

Numeric values are stored with the least significant byte first.

The module supports two versions of the data format: version 0 is the historical version, version 1 shares interned strings in the file, and upon unmarshalling. Version 2 uses a binary format for floating point numbers. `Py_MARSHAL_VERSION` indicates the current file format (currently 2).

`void PyMarshal_WriteLongToFile(long value, FILE *file, int version)`

Marshal a long integer, *value*, to *file*. This will only write the least-significant 32 bits of *value*; regardless of the size of the native long type. *version* indicates the file format.

This function can fail, in which case it sets the error indicator. Use `PyErr_Occurred()` to check for that.

`void PyMarshal_WriteObjectToFile(PyObject *value, FILE *file, int version)`

Marshal a Python object, *value*, to *file*. *version* indicates the file format.

This function can fail, in which case it sets the error indicator. Use `PyErr_Occurred()` to check for that.

`PyObject *PyMarshal_WriteObjectToString(PyObject *value, int version)`

*Return value:* New reference.

Return a bytes object containing the marshalled representation of *value*. *version* indicates the file format.

The following functions allow marshalled values to be read back in.

`long PyMarshal_ReadLongFromFile(FILE *file)`

Return a C long from the data stream in a FILE\* opened for reading. Only a 32-bit value can be read in using this function, regardless of the native size of long.

On error, sets the appropriate exception (**EOFError**) and returns `-1`.

`int PyMarshal_ReadShortFromFile(FILE *file)`

Return a C short from the data stream in a FILE\* opened for reading. Only a 16-bit value can be read in using this function, regardless of the native size of short.

On error, sets the appropriate exception (**EOFError**) and returns `-1`.

**PyObject** \*PyMarshal\_ReadObjectFromFile(FILE \*file)

*Return value:* New reference.

Return a Python object from the data stream in a FILE\* opened for reading.

On error, sets the appropriate exception (**EOFError**, **ValueError** or **TypeError**) and returns `NULL`.

**PyObject** \*PyMarshal\_ReadLastObjectFromFile(FILE \*file)

*Return value:* New reference.

Return a Python object from the data stream in a FILE\* opened for reading. Unlike

**PyMarshal\_ReadObjectFromFile()**, this function assumes that no further objects will be read from the file, allowing it to aggressively load file data into memory so that the de-serialization can operate from data in memory rather than reading a byte at a time from the file. Only use these

variant if you are certain that you won't be reading anything else from the file.

On error, sets the appropriate exception (**EOFError**, **ValueError** or **TypeError**) and returns `NULL`.

**PyObject** \*PyMarshal\_ReadObjectFromString(const char \*data,  
**Py\_ssize\_t** len)

*Return value: New reference.*

Return a Python object from the data stream in a byte buffer containing *len* bytes pointed to by *data*.

On error, sets the appropriate exception (**EOFError**, **ValueError** or **TypeError**) and returns `NULL`.

# Parsing arguments and building values

These functions are useful when creating your own extensions functions and methods. Additional information and examples are available in [Extending and Embedding the Python Interpreter](#).

The first three of these functions described, `PyArg_ParseTuple()`, `PyArg_ParseTupleAndKeywords()`, and `PyArg_Parse()`, all use *format strings* which are used to tell the function about the expected arguments. The format strings use the same syntax for each of these functions.

## Parsing arguments

A format string consists of zero or more “format units.” A format unit describes one Python object; it is usually a single character or a parenthesized sequence of format units. With a few exceptions, a format unit that is not a parenthesized sequence normally corresponds to a single address argument to these functions. In the following description, the quoted form is the format unit; the entry in (round) parentheses is the Python object type that matches the format unit; and the entry in [square] brackets is the type of the C variable(s) whose address should be passed.

## Strings and buffers

These formats allow accessing an object as a contiguous chunk of memory. You don’t have to provide raw storage for the returned unicode or bytes area.

Unless otherwise stated, buffers are not NUL-terminated.

There are three ways strings and buffers can be converted to C:

- Formats such as `y*` and `s*` fill a `Py_buffer` structure. This locks the underlying buffer so that the caller can subsequently use the buffer even inside a `Py_BEGIN_ALLOW_THREADS` block without the risk of mutable data being resized or destroyed. As a result, **you have to call `PyBuffer_Release()`** after you have finished processing the data (or in any early abort case).
- The `es`, `es#`, `et` and `et#` formats allocate the result buffer. **You have to call `PyMem_Free()`** after you have finished processing the data (or in any early abort case).
- Other formats take a `str` or a read-only bytes-like object, such as `bytes`, and provide a `const char *` pointer to its buffer. In this case the buffer is “borrowed”: it is managed by the corresponding Python object, and shares the lifetime of this object. You won’t have to release any memory yourself.

To ensure that the underlying buffer may be safely borrowed, the object’s `PyBufferProcs.bf_releasebuffer` field must be `NULL`. This disallows common mutable objects such as `bytearray`, but also some read-only objects such as `memoryview` of `bytes`.

Besides this `bf_releasebuffer` requirement, there is no check to verify whether the input object is immutable (e.g. whether it would honor a request for a writable buffer, or whether another thread can mutate the data).

## Note

For all `#` variants of formats (`s#`, `y#`, etc.), the macro `PY_SSIZE_T_CLEAN` must be defined before including `Python.h`. On Python 3.9 and older, the type of the length argument is `Py_ssize_t` if the `PY_SSIZE_T_CLEAN` macro is defined, or `int` otherwise.

`s (str) [const char *]`

Convert a Unicode object to a C pointer to a character string. A pointer to an existing string is stored in the character

pointer variable whose address you pass. The C string is NUL-terminated. The Python string must not contain embedded null code points; if it does, a `ValueError` exception is raised. Unicode objects are converted to C strings using `'utf-8'` encoding. If this conversion fails, a `UnicodeError` is raised.

### Note

This format does not accept `bytes-like objects`. If you want to accept filesystem paths and convert them to C character strings, it is preferable to use the `o&` format with `PyUnicode_FSConverter()` as *converter*.

*Changed in version 3.5:* Previously, `TypeError` was raised when embedded null code points were encountered in the Python string.

`s*` (`str` or `bytes-like object`) [`Py_buffer`]

This format accepts Unicode objects as well as bytes-like objects. It fills a `Py_buffer` structure provided by the caller. In this case the resulting C string may contain embedded NUL bytes. Unicode objects are converted to C strings using `'utf-8'` encoding.

`s#` (`str`, read-only `bytes-like object`) [`const char *`, `Py_ssize_t`]

Like `s*`, except that it provides a `borrowed buffer`. The result is stored into two C variables, the first one a pointer to a C string, the second one its length. The string may contain embedded null bytes. Unicode objects are converted to C strings using `'utf-8'` encoding.

`z` (`str` or `None`) [`const char *`]

Like `s`, but the Python object may also be `None`, in which case the C pointer is set to `NULL`.

`z*` (`str`, `bytes-like object` or `None`) [`Py_buffer`]

Like `s*`, but the Python object may also be `None`, in which case the `buf` member of the `Py_buffer` structure is set to `NULL`.

z# (**str**, read-only **bytes-like object** or None) [const char \*, **Py\_ssize\_t**]

Like s#, but the Python object may also be None, in which case the C pointer is set to NULL.

y (read-only **bytes-like object**) [const char \*]

This format converts a bytes-like object to a C pointer to a **borrowed** character string; it does not accept Unicode objects. The bytes buffer must not contain embedded null bytes; if it does, a **ValueError** exception is raised.

*Changed in version 3.5:* Previously, **TypeError** was raised when embedded null bytes were encountered in the bytes buffer.

y\* (**bytes-like object**) [Py\_buffer]

This variant on s\* doesn't accept Unicode objects, only bytes-like objects. **This is the recommended way to accept binary data.**

y# (read-only **bytes-like object**) [const char \*, **Py\_ssize\_t**]

This variant on s# doesn't accept Unicode objects, only bytes-like objects.

S (**bytes**) [PyBytesObject \*]

Requires that the Python object is a **bytes** object, without attempting any conversion. Raises **TypeError** if the object is not a bytes object. The C variable may also be declared as **PyObject\***.

Y (**bytearray**) [PyByteArrayObject \*]

Requires that the Python object is a **bytearray** object, without attempting any conversion. Raises **TypeError** if the object is not a **bytearray** object. The C variable may also be declared as **PyObject\***.

U (**str**) [PyObject \*]

Requires that the Python object is a Unicode object, without attempting any conversion. Raises **TypeError** if the object is not a Unicode object. The C variable may also be declared

as `PyObject*`.

`w*` (read-write `bytes-like object`) [`Py_buffer`]

This format accepts any object which implements the read-write buffer interface. It fills a `Py_buffer` structure provided by the caller. The buffer may contain embedded null bytes. The caller have to call `PyBuffer_Release()` when it is done with the buffer.

`es` (`str`) [`const char *encoding`, `char **buffer`]

This variant on `s` is used for encoding Unicode into a character buffer. It only works for encoded data without embedded NUL bytes.

This format requires two arguments. The first is only used as input, and must be a `const char*` which points to the name of an encoding as a NUL-terminated string, or `NULL`, in which case `'utf-8'` encoding is used. An exception is raised if the named encoding is not known to Python. The second argument must be a `char**`; the value of the pointer it references will be set to a buffer with the contents of the argument text. The text will be encoded in the encoding specified by the first argument.

`PyArg_ParseTuple()` will allocate a buffer of the needed size, copy the encoded data into this buffer and adjust `*buffer` to reference the newly allocated storage. The caller is responsible for calling `PyMem_Free()` to free the allocated buffer after use.

`et` (`str`, `bytes` or `bytearray`) [`const char *encoding`, `char **buffer`]

Same as `es` except that byte string objects are passed through without recoding them. Instead, the implementation assumes that the byte string object uses the encoding passed in as parameter.

`es#` (`str`) [`const char *encoding`, `char **buffer`, `Py_ssize_t *buffer_length`]

This variant on `s#` is used for encoding Unicode into a

character buffer. Unlike the `es` format, this variant allows input data which contains NUL characters.

It requires three arguments. The first is only used as input, and must be a `const char*` which points to the name of an encoding as a NUL-terminated string, or `NULL`, in which case `'utf-8'` encoding is used. An exception is raised if the named encoding is not known to Python. The second argument must be a `char**`; the value of the pointer it references will be set to a buffer with the contents of the argument text. The text will be encoded in the encoding specified by the first argument. The third argument must be a pointer to an integer; the referenced integer will be set to the number of bytes in the output buffer.

There are two modes of operation:

If `*buffer` points a `NULL` pointer, the function will allocate a buffer of the needed size, copy the encoded data into this buffer and set `*buffer` to reference the newly allocated storage. The caller is responsible for calling `PyMem_Free()` to free the allocated buffer after usage.

If `*buffer` points to a non-`NULL` pointer (an already allocated buffer), `PyArg_ParseTuple()` will use this location as the buffer and interpret the initial value of `*buffer_length` as the buffer size. It will then copy the encoded data into the buffer and NUL-terminate it. If the buffer is not large enough, a `ValueError` will be set.

In both cases, `*buffer_length` is set to the length of the encoded data without the trailing NUL byte.

`et# (str, bytes or bytearray) [const char *encoding, char **buffer, Py_ssize_t *buffer_length]`

Same as `es#` except that byte string objects are passed through without recoding them. Instead, the implementation assumes that the byte string object uses the encoding passed in as parameter.

*Changed in version 3.12:* `u`, `u#`, `Z`, and `Z#` are removed because

they used a legacy `Py_UNICODE*` representation.

## Numbers

**b** ([int](#)) [unsigned char]

Convert a nonnegative Python integer to an unsigned tiny int, stored in a C unsigned char.

**B** ([int](#)) [unsigned char]

Convert a Python integer to a tiny int without overflow checking, stored in a C unsigned char.

**h** ([int](#)) [short int]

Convert a Python integer to a C short int.

**H** ([int](#)) [unsigned short int]

Convert a Python integer to a C unsigned short int, without overflow checking.

**i** ([int](#)) [int]

Convert a Python integer to a plain C int.

**I** ([int](#)) [unsigned int]

Convert a Python integer to a C unsigned int, without overflow checking.

**l** ([int](#)) [long int]

Convert a Python integer to a C long int.

**k** ([int](#)) [unsigned long]

Convert a Python integer to a C unsigned long without overflow checking.

**L** ([int](#)) [long long]

Convert a Python integer to a C long long.

**K** ([int](#)) [unsigned long long]

Convert a Python integer to a C unsigned long long without overflow checking.

n (**int**) [**Py\_ssize\_t**]

Convert a Python integer to a C **Py\_ssize\_t**.

c (**bytes** or **bytearray** of length 1) [**char**]

Convert a Python byte, represented as a **bytes** or **bytearray** object of length 1, to a C char.

*Changed in version 3.3:* Allow **bytearray** objects.

C (**str** of length 1) [**int**]

Convert a Python character, represented as a **str** object of length 1, to a C int.

f (**float**) [**float**]

Convert a Python floating point number to a C float.

d (**float**) [**double**]

Convert a Python floating point number to a C double.

D (**complex**) [**Py\_complex**]

Convert a Python complex number to a C **Py\_complex** structure.

## Other objects

O (object) [**PyObject \***]

Store a Python object (without any conversion) in a C object pointer. The C program thus receives the actual object that was passed. A new **strong reference** to the object is not created (i.e. its reference count is not increased). The pointer stored is not `NULL`.

O! (object) [**typeobject**, **PyObject \***]

Store a Python object in a C object pointer. This is similar to O, but takes two C arguments: the first is the address of a Python type object, the second is the address of the C variable (of type **PyObject\***) into which the object pointer is stored. If the Python object does not have the required type, **TypeError** is raised.

O& (object) [*converter*, *anything*]

Convert a Python object to a C variable through a *converter* function. This takes two arguments: the first is a function, the second is the address of a C variable (of arbitrary type), converted to void\*. The *converter* function in turn is called as follows:

```
status = converter(object, address);
```

where *object* is the Python object to be converted and *address* is the void\* argument that was passed to the `PyArg_Parse*` function. The returned *status* should be 1 for a successful conversion and 0 if the conversion has failed. When the conversion fails, the *converter* function should raise an exception and leave the content of *address* unmodified.

If the *converter* returns `Py_CLEANUP_SUPPORTED`, it may get called a second time if the argument parsing eventually fails, giving the converter a chance to release any memory that it had already allocated. In this second call, the *object* parameter will be `NULL`; *address* will have the same value as in the original call.

*Changed in version 3.1:* `Py_CLEANUP_SUPPORTED` was added.

p (**bool**) [int]

Tests the value passed in for truth (a boolean predicate) and converts the result to its equivalent C true/false integer value. Sets the int to 1 if the expression was true and 0 if it was false. This accepts any valid Python value. See [Truth Value Testing](#) for more information about how Python tests values for truth.

*New in version 3.3.*

(items) (**tuple**) [*matching-items*]

The object must be a Python sequence whose length is the number of format units in *items*. The C arguments must correspond to the individual format units in *items*. Format

units for sequences may be nested.

It is possible to pass “long” integers (integers whose value exceeds the platform’s **LONG\_MAX**) however no proper range checking is done — the most significant bits are silently truncated when the receiving field is too small to receive the value (actually, the semantics are inherited from downcasts in C — your mileage may vary).

A few other characters have a meaning in a format string. These may not occur inside nested parentheses. They are:

|

Indicates that the remaining arguments in the Python argument list are optional. The C variables corresponding to optional arguments should be initialized to their default value — when an optional argument is not specified, **PyArg\_ParseTuple()** does not touch the contents of the corresponding C variable(s).

\$

**PyArg\_ParseTupleAndKeywords()** only: Indicates that the remaining arguments in the Python argument list are keyword-only. Currently, all keyword-only arguments must also be optional arguments, so | must always be specified before \$ in the format string.

*New in version 3.3.*

:

The list of format units ends here; the string after the colon is used as the function name in error messages (the “associated value” of the exception that **PyArg\_ParseTuple()** raises).

;

The list of format units ends here; the string after the semicolon is used as the error message *instead* of the default error message. : and ; mutually exclude each other.

Note that any Python object references which are provided to the

caller are *borrowed* references; do not release them (i.e. do not decrement their reference count)!

Additional arguments passed to these functions must be addresses of variables whose type is determined by the format string; these are used to store values from the input tuple. There are a few cases, as described in the list of format units above, where these parameters are used as input values; they should match what is specified for the corresponding format unit in that case.

For the conversion to succeed, the *arg* object must match the format and the format must be exhausted. On success, the `PyArg_Parse*` functions return true, otherwise they return false and raise an appropriate exception. When the `PyArg_Parse*` functions fail due to conversion failure in one of the format units, the variables at the addresses corresponding to that and the following format units are left untouched.

## API Functions

`int PyArg_ParseTuple(PyObject *args, const char *format, ...)`

*Part of the [Stable ABI](#).*

Parse the parameters of a function that takes only positional parameters into local variables. Returns true on success; on failure, it returns false and raises the appropriate exception.

`int PyArg_VaParse(PyObject *args, const char *format, va_list  
vargs)`

*Part of the [Stable ABI](#).*

Identical to `PyArg_ParseTuple()`, except that it accepts a *va\_list* rather than a variable number of arguments.

`int PyArg_ParseTupleAndKeywords(PyObject *args, PyObject *kw,  
const char *format, char *keywords[], ...)`

*Part of the [Stable ABI](#).*

Parse the parameters of a function that takes both positional and keyword parameters into local variables. The *keywords* argument is a NULL-terminated array of keyword parameter

names. Empty names denote [positional-only parameters](#). Returns true on success; on failure, it returns false and raises the appropriate exception.

*Changed in version 3.6:* Added support for [positional-only parameters](#).

```
int PyArg_VaParseTupleAndKeywords(PyObject *args, PyObject
*kw, const char *format, char *keywords[], va_list vargs)
```

*Part of the [Stable ABI](#).*

Identical to [PyArg\\_ParseTupleAndKeywords\(\)](#), except that it accepts a `va_list` rather than a variable number of arguments.

```
int PyArg_ValidateKeywordArguments(PyObject*)
```

*Part of the [Stable ABI](#).*

Ensure that the keys in the keywords argument dictionary are strings. This is only needed if

[PyArg\\_ParseTupleAndKeywords\(\)](#) is not used, since the latter already does this check.

*New in version 3.2.*

```
int PyArg_Parse(PyObject *args, const char *format, ...)
```

*Part of the [Stable ABI](#).*

Function used to deconstruct the argument lists of “old-style” functions — these are functions which use the **METH\_OLDARGS** parameter parsing method, which has been removed in Python 3. This is not recommended for use in parameter parsing in new code, and most code in the standard interpreter has been modified to no longer use this for that purpose. It does remain a convenient way to decompose other tuples, however, and may continue to be used for that purpose.

```
int PyArg_UnpackTuple(PyObject *args, const char *name,
Py_ssize_t min, Py_ssize_t max, ...)
```

*Part of the [Stable ABI](#).*

A simpler form of parameter retrieval which does not use a format string to specify the types of the arguments. Functions which use this method to retrieve their parameters should be declared as `METH_VARARGS` in function or method tables. The tuple containing the actual parameters should be passed as *args*; it must actually be a tuple. The length of the tuple must be at least *min* and no more than *max*; *min* and *max* may be equal. Additional arguments must be passed to the function, each of which should be a pointer to a `PyObject*` variable; these will be filled in with the values from *args*; they will contain [borrowed references](#). The variables which correspond to optional parameters not given by *args* will not be filled in; these should be initialized by the caller. This function returns true on success and false if *args* is not a tuple or contains the wrong number of elements; an exception will be set if there was a failure.

This is an example of the use of this function, taken from the sources for the `_weakref` helper module for weak references:

```
static PyObject *
weakref_ref(PyObject *self, PyObject *args)
{
    PyObject *object;
    PyObject *callback = NULL;
    PyObject *result = NULL;

    if (PyArg_UnpackTuple(args, "ref", 1, 2, &object,
                          &callback) == 0)
        result = PyWeakref_NewRef(object, callback);
    return result;
}
```

The call to `PyArg_UnpackTuple()` in this example is entirely equivalent to this call to `PyArg_ParseTuple()`:

```
PyArg_ParseTuple(args, "O|O:ref", &object, &callback)
```

# Building values

**PyObject** \*Py\_BuildValue(const char \*format, ...)

*Return value:* New reference. Part of the [Stable ABI](#).

Create a new value based on a format string similar to those accepted by the `PyArg_Parse*` family of functions and a sequence of values. Returns the value or `NULL` in the case of an error; an exception will be raised if `NULL` is returned.

**Py\_BuildValue()** does not always build a tuple. It builds a tuple only if its format string contains two or more format units. If the format string is empty, it returns `None`; if it contains exactly one format unit, it returns whatever object is described by that format unit. To force it to return a tuple of size 0 or one, parenthesize the format string.

When memory buffers are passed as parameters to supply data to build objects, as for the `s` and `s#` formats, the required data is copied. Buffers provided by the caller are never referenced by the objects created by

**Py\_BuildValue()**. In other words, if your code invokes **malloc()** and passes the allocated memory to **Py\_BuildValue()**, your code is responsible for calling **free()** for that memory once **Py\_BuildValue()** returns.

In the following description, the quoted form is the format unit; the entry in (round) parentheses is the Python object type that the format unit will return; and the entry in [square] brackets is the type of the C value(s) to be passed.

The characters space, tab, colon and comma are ignored in format strings (but not within format units such as `s#`). This can be used to make long format strings a tad more readable.

`s` (**str** or `None`) [const char \*]

Convert a null-terminated C string to a Python **str** object using 'utf-8' encoding. If the C string pointer is `NULL`, `None` is used.

`s#` (**str** or `None`) [const char \*, **Py\_ssize\_t**]

Convert a C string and its length to a Python **str** object using 'utf-8' encoding. If the C string pointer is NULL, the length is ignored and None is returned.

y (**bytes**) [const char \*]

This converts a C string to a Python **bytes** object. If the C string pointer is NULL, None is returned.

y# (**bytes**) [const char \*, **Py\_ssize\_t**]

This converts a C string and its lengths to a Python object. If the C string pointer is NULL, None is returned.

z (**str** or None) [const char \*]

Same as s.

z# (**str** or None) [const char \*, **Py\_ssize\_t**]

Same as s#.

u (**str**) [const wchar\_t \*]

Convert a null-terminated **wchar\_t** buffer of Unicode (UTF-16 or UCS-4) data to a Python Unicode object. If the Unicode buffer pointer is NULL, None is returned.

u# (**str**) [const wchar\_t \*, **Py\_ssize\_t**]

Convert a Unicode (UTF-16 or UCS-4) data buffer and its length to a Python Unicode object. If the Unicode buffer pointer is NULL, the length is ignored and None is returned.

U (**str** or None) [const char \*]

Same as s.

U# (**str** or None) [const char \*, **Py\_ssize\_t**]

Same as s#.

i (**int**) [int]

Convert a plain C int to a Python integer object.

b (**int**) [char]

Convert a plain C char to a Python integer object.

- h (**int**) [short int]  
Convert a plain C short int to a Python integer object.
- l (**int**) [long int]  
Convert a C long int to a Python integer object.
- B (**int**) [unsigned char]  
Convert a C unsigned char to a Python integer object.
- H (**int**) [unsigned short int]  
Convert a C unsigned short int to a Python integer object.
- I (**int**) [unsigned int]  
Convert a C unsigned int to a Python integer object.
- k (**int**) [unsigned long]  
Convert a C unsigned long to a Python integer object.
- L (**int**) [long long]  
Convert a C long long to a Python integer object.
- K (**int**) [unsigned long long]  
Convert a C unsigned long long to a Python integer object.
- n (**int**) [**Py\_ssize\_t**]  
Convert a C **Py\_ssize\_t** to a Python integer.
- c (**bytes** of length 1) [char]  
Convert a C int representing a byte to a Python **bytes** object of length 1.
- C (**str** of length 1) [int]  
Convert a C int representing a character to Python **str** object of length 1.
- d (**float**) [double]  
Convert a C double to a Python floating point number.
- f (**float**) [float]  
Convert a C float to a Python floating point number.

D (**complex**) [Py\_complex \*]

Convert a C **Py\_complex** structure to a Python complex number.

O (object) [PyObject \*]

Pass a Python object untouched but create a new **strong reference** to it (i.e. its reference count is incremented by one). If the object passed in is a NULL pointer, it is assumed that this was caused because the call producing the argument found an error and set an exception. Therefore, **Py\_BuildValue()** will return NULL but won't raise an exception. If no exception has been raised yet, **SystemError** is set.

S (object) [PyObject \*]

Same as O.

N (object) [PyObject \*]

Same as O, except it doesn't create a new **strong reference**. Useful when the object is created by a call to an object constructor in the argument list.

O& (object) [*converter, anything*]

Convert *anything* to a Python object through a *converter* function. The function is called with *anything* (which should be compatible with void\*) as its argument and should return a "new" Python object, or NULL if an error occurred.

(items) (**tuple**) [*matching-items*]

Convert a sequence of C values to a Python tuple with the same number of items.

[items] (**list**) [*matching-items*]

Convert a sequence of C values to a Python list with the same number of items.

{items} (**dict**) [*matching-items*]

Convert a sequence of C values to a Python dictionary. Each pair of consecutive C values adds one item to the dictionary, serving as key and value, respectively.

If there is an error in the format string, the `SystemError` exception is set and `NULL` returned.

`PyObject *``Py_VaBuildValue`(`const char *``format`, `va_list` `vargs`)

*Return value:* New reference. Part of the [Stable ABI](#).

Identical to `Py_BuildValue()`, except that it accepts a `va_list` rather than a variable number of arguments.

# String conversion and formatting

Functions for number conversion and formatted string output.

```
int PyOS_snprintf(char *str, size_t size, const char *format, ...)
```

*Part of the [Stable ABI](#).*

Output not more than *size* bytes to *str* according to the format string *format* and the extra arguments. See the Unix man page [snprintf\(3\)](#).

```
int PyOS_vsnprintf(char *str, size_t size, const char *format, va_list va)
```

*Part of the [Stable ABI](#).*

Output not more than *size* bytes to *str* according to the format string *format* and the variable argument list *va*. Unix man page [vsnprintf\(3\)](#).

[PyOS\\_snprintf\(\)](#) and [PyOS\\_vsnprintf\(\)](#) wrap the Standard C library functions `snprintf()` and `vsnprintf()`. Their purpose is to guarantee consistent behavior in corner cases, which the Standard C functions do not.

The wrappers ensure that `str[size-1]` is always `'\0'` upon return. They never write more than *size* bytes (including the trailing `'\0'`) into *str*. Both functions require that `str != NULL`, `size > 0`, `format != NULL` and `size < INT_MAX`. Note that this means there is no equivalent to the C99 `n = snprintf(NULL, 0, ...)` which would determine the necessary buffer size.

The return value (*rv*) for these functions should be interpreted as follows:

- When `0 <= rv < size`, the output conversion was

successful and *rv* characters were written to *str* (excluding the trailing `'\0'` byte at `str[rv]`).

- When `rv >= size`, the output conversion was truncated and a buffer with `rv + 1` bytes would have been needed to succeed. `str[size-1]` is `'\0'` in this case.
- When `rv < 0`, “something bad happened.” `str[size-1]` is `'\0'` in this case too, but the rest of *str* is undefined. The exact cause of the error depends on the underlying platform.

The following functions provide locale-independent string to number conversions.

`double PyOS_string_to_double(const char *s, char **endptr, PyObject *overflow_exception)`

*Part of the [Stable ABI](#).*

Convert a string *s* to a double, raising a Python exception on failure. The set of accepted strings corresponds to the set of strings accepted by Python’s `float()` constructor, except that *s* must not have leading or trailing whitespace. The conversion is independent of the current locale.

If *endptr* is `NULL`, convert the whole string. Raise `ValueError` and return `-1.0` if the string is not a valid representation of a floating-point number.

If *endptr* is not `NULL`, convert as much of the string as possible and set *\*endptr* to point to the first unconverted character. If no initial segment of the string is the valid representation of a floating-point number, set *\*endptr* to point to the beginning of the string, raise `ValueError`, and return `-1.0`.

If *s* represents a value that is too large to store in a float (for example, `"1e500"` is such a string on many platforms) then if *overflow\_exception* is `NULL` return `Py_HUGE_VAL` (with an appropriate sign) and don’t set any exception. Otherwise, *overflow\_exception* must point to a Python exception object; raise that exception and return `-1.0`. In both cases, set *\*endptr* to point to the first character after the converted value.

If any other error occurs during the conversion (for example an out-of-memory error), set the appropriate Python exception and return `-1.0`.

*New in version 3.1.*

`char *PyOS_double_to_string(double val, char format_code, int precision, int flags, int *ptype)`

Part of the [Stable ABI](#).

Convert a double *val* to a string using supplied *format\_code*, *precision*, and *flags*.

*format\_code* must be one of `'e'`, `'E'`, `'f'`, `'F'`, `'g'`, `'G'` or `'r'`. For `'r'`, the supplied *precision* must be 0 and is ignored. The `'r'` format code specifies the standard [repr\(\)](#) format.

*flags* can be zero or more of the values `Py_DTST_SIGN`, `Py_DTST_ADD_DOT_0`, or `Py_DTST_ALT`, or-ed together:

- `Py_DTST_SIGN` means to always precede the returned string with a sign character, even if *val* is non-negative.
- `Py_DTST_ADD_DOT_0` means to ensure that the returned string will not look like an integer.
- `Py_DTST_ALT` means to apply “alternate” formatting rules. See the documentation for the [PyOS\\_snprintf\(\)](#) `'#'` specifier for details.

If *ptype* is non-NULL, then the value it points to will be set to one of `Py_DTST_FINITE`, `Py_DTST_INFINITE`, or `Py_DTST_NAN`, signifying that *val* is a finite number, an infinite number, or not a number, respectively.

The return value is a pointer to *buffer* with the converted string or `NULL` if the conversion failed. The caller is responsible for freeing the returned string by calling [PyMem\\_Free\(\)](#).

*New in version 3.1.*

`int PyOS_stricmp(const char *s1, const char *s2)`

Case insensitive comparison of strings. The function works almost identically to **`strcmp()`** except that it ignores the case.

`int PyOS_strnicmp(const char *s1, const char *s2, Py\_ssize\_t size)`

Case insensitive comparison of strings. The function works almost identically to **`strncmp()`** except that it ignores the case.

# Reflection

**PyObject** \*PyEval\_GetBuiltins(void)

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Return a dictionary of the builtins in the current execution frame, or the interpreter of the thread state if no frame is currently executing.

**PyObject** \*PyEval\_GetLocals(void)

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Return a dictionary of the local variables in the current execution frame, or `NULL` if no frame is currently executing.

**PyObject** \*PyEval\_GetGlobals(void)

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Return a dictionary of the global variables in the current execution frame, or `NULL` if no frame is currently executing.

**PyFrameObject** \*PyEval\_GetFrame(void)

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Return the current thread state's frame, which is `NULL` if no frame is currently executing.

See also [PyThreadState\\_GetFrame\(\)](#).

const char \*PyEval\_GetFuncName(**PyObject** \*func)

*Part of the [Stable ABI](#).*

Return the name of *func* if it is a function, class or instance object, else the name of *funcs* type.

const char \*PyEval\_GetFuncDesc(**PyObject** \*func)

*Part of the [Stable ABI](#).*

Return a description string, depending on the type of *func*.

Return values include “()” for functions and methods, “ constructor”, “ instance”, and “ object”. Concatenated with the result of `PyEval_GetFuncName()`, the result will be a description of *func*.

# Codec registry and support functions

`int PyCodec_Register(PyObject *search_function)`

*Part of the [Stable ABI](#).*

Register a new codec search function.

As side effect, this tries to load the **encodings** package, if not yet done, to make sure that it is always first in the list of search functions.

`int PyCodec_Unregister(PyObject *search_function)`

*Part of the [Stable ABI](#) since version 3.10.*

Unregister a codec search function and clear the registry's cache. If the search function is not registered, do nothing. Return 0 on success. Raise an exception and return -1 on error.

*New in version 3.10.*

`int PyCodec_KnownEncoding(const char *encoding)`

*Part of the [Stable ABI](#).*

Return 1 or 0 depending on whether there is a registered codec for the given *encoding*. This function always succeeds.

`PyObject *PyCodec_Encode(PyObject *object, const char *encoding, const char *errors)`

*Return value: New reference. Part of the [Stable ABI](#).*

Generic codec based encoding API.

*object* is passed through the encoder function found for the given *encoding* using the error handling method defined by *errors*. *errors* may be `NULL` to use the default method defined

for the codec. Raises a **LookupError** if no encoder can be found.

**PyObject** \*PyCodec\_Decode(PyObject \*object, const char \*encoding, const char \*errors)

*Return value: New reference. Part of the [Stable ABI](#).*

Generic codec based decoding API.

*object* is passed through the decoder function found for the given *encoding* using the error handling method defined by *errors*. *errors* may be `NULL` to use the default method defined for the codec. Raises a **LookupError** if no encoder can be found.

## Codec lookup API

In the following functions, the *encoding* string is looked up converted to all lower-case characters, which makes encodings looked up through this mechanism effectively case-insensitive. If no codec is found, a **KeyError** is set and `NULL` returned.

**PyObject** \*PyCodec\_Encoder(const char \*encoding)

*Return value: New reference. Part of the [Stable ABI](#).*

Get an encoder function for the given *encoding*.

**PyObject** \*PyCodec\_Decoder(const char \*encoding)

*Return value: New reference. Part of the [Stable ABI](#).*

Get a decoder function for the given *encoding*.

**PyObject** \*PyCodec\_IncrementalEncoder(const char \*encoding, const char \*errors)

*Return value: New reference. Part of the [Stable ABI](#).*

Get an **IncrementalEncoder** object for the given *encoding*.

**PyObject** \*PyCodec\_IncrementalDecoder(const char \*encoding, const char \*errors)

*Return value: New reference. Part of the [Stable ABI](#).*

Get an [IncrementalDecoder](#) object for the given *encoding*.

[PyObject](#) \*PyCodec\_StreamReader(const char \*encoding, [PyObject](#) \*stream, const char \*errors)

*Return value: New reference. Part of the [Stable ABI](#).*

Get a [StreamReader](#) factory function for the given *encoding*.

[PyObject](#) \*PyCodec\_StreamWriter(const char \*encoding, [PyObject](#) \*stream, const char \*errors)

*Return value: New reference. Part of the [Stable ABI](#).*

Get a [StreamWriter](#) factory function for the given *encoding*.

## Registry API for Unicode encoding error handlers

int PyCodec\_RegisterError(const char \*name, [PyObject](#) \*error)

*Part of the [Stable ABI](#).*

Register the error handling callback function *error* under the given *name*. This callback function will be called by a codec when it encounters unencodable characters/undecodable bytes and *name* is specified as the error parameter in the call to the encode/decode function.

The callback gets a single argument, an instance of [UnicodeEncodeError](#), [UnicodeDecodeError](#) or [UnicodeTranslateError](#) that holds information about the problematic sequence of characters or bytes and their offset in the original string (see [Unicode Exception Objects](#) for functions to extract this information). The callback must either raise the given exception, or return a two-item tuple containing the replacement for the problematic sequence, and an integer giving the offset in the original string at which encoding/decoding should be resumed.

Return 0 on success, -1 on error.

**PyObject \***PyCodec\_LookupError(const char \*name)

*Return value:* New reference. Part of the [Stable ABI](#).

Lookup the error handling callback function registered under *name*. As a special case NULL can be passed, in which case the error handling callback for “strict” will be returned.

**PyObject \***PyCodec\_StrictErrors(**PyObject \***exc)

*Return value:* Always NULL. Part of the [Stable ABI](#).

Raise *exc* as an exception.

**PyObject \***PyCodec\_IgnoreErrors(**PyObject \***exc)

*Return value:* New reference. Part of the [Stable ABI](#).

Ignore the unicode error, skipping the faulty input.

**PyObject \***PyCodec\_ReplaceErrors(**PyObject \***exc)

*Return value:* New reference. Part of the [Stable ABI](#).

Replace the unicode encode error with ? or U+FFFD.

**PyObject \***PyCodec\_XMLCharRefReplaceErrors(**PyObject \***exc)

*Return value:* New reference. Part of the [Stable ABI](#).

Replace the unicode encode error with XML character references.

**PyObject \***PyCodec\_BackslashReplaceErrors(**PyObject \***exc)

*Return value:* New reference. Part of the [Stable ABI](#).

Replace the unicode encode error with backslash escapes (\x, \u and \U).

**PyObject \***PyCodec\_NameReplaceErrors(**PyObject \***exc)

*Return value:* New reference. Part of the [Stable ABI](#) since version 3.7.

Replace the unicode encode error with \N{...} escapes.

*New in version 3.5.*

# Support for Perf Maps

On supported platforms (as of this writing, only Linux), the runtime can take advantage of *perf map files* to make Python functions visible to an external profiling tool (such as [perf](https://perf.wiki.kernel.org/index.php/Main_Page) [https://perf.wiki.kernel.org/index.php/Main\_Page]). A running process may create a file in the `/tmp` directory, which contains entries that can map a section of executable code to a name. This interface is described in the [documentation of the Linux Perf tool](https://git.kernel.org/pub/scm/linux/kernel/git/torvalds/linux.git/tree/tools/perf/Documentation/jit-interface.txt) [https://git.kernel.org/pub/scm/linux/kernel/git/torvalds/linux.git/tree/tools/perf/Documentation/jit-interface.txt].

In Python, these helper APIs can be used by libraries and features that rely on generating machine code on the fly.

Note that holding the Global Interpreter Lock (GIL) is not required for these APIs.

```
int PyUnstable_PerfMapState_Init(void)
```

*This is **Unstable API**. It may change without warning in minor releases.*

Open the `/tmp/perf-$pid.map` file, unless it's already opened, and create a lock to ensure thread-safe writes to the file (provided the writes are done through [PyUnstable\\_WritePerfMapEntry\(\)](#)). Normally, there's no need to call this explicitly; just use [PyUnstable\\_WritePerfMapEntry\(\)](#) and it will initialize the state on first call.

Returns `0` on success, `-1` on failure to create/open the perf map file, or `-2` on failure to create a lock. Check `errno` for more information about the cause of a failure.

```
int PyUnstable_WritePerfMapEntry(const void *code_addr, unsigned
```

```
int code_size, const char *entry_name)
```

*This is **Unstable API**. It may change without warning in minor releases.*

Write one single entry to the `/tmp/perf-$pid.map` file. This function is thread safe. Here is what an example entry looks like:

```
# address      size  name
7f3529fcf759 b    py::bar:/run/t.py
```

Will call **PyUnstable\_PerfMapState\_Init()** before writing the entry, if the perf map file is not already opened. Returns `0` on success, or the same error codes as **PyUnstable\_PerfMapState\_Init()** on failure.

```
void PyUnstable_PerfMapState_Fini(void)
```

*This is **Unstable API**. It may change without warning in minor releases.*

Close the perf map file opened by **PyUnstable\_PerfMapState\_Init()**. This is called by the runtime itself during interpreter shut-down. In general, there shouldn't be a reason to explicitly call this, except to handle specific scenarios such as forking.

# Abstract Objects Layer

The functions in this chapter interact with Python objects regardless of their type, or with wide classes of object types (e.g. all numerical types, or all sequence types). When used on object types for which they do not apply, they will raise a Python exception.

It is not possible to use these functions on objects that are not properly initialized, such as a list object that has been created by `PyList_New()`, but whose items have not been set to some non-NULL value yet.

    - request-independent fields
    - readonly, format
    - shape, strides, suboffsets
    - contiguity requests

- compound requests
- Complex arrays
  - NumPy-style: shape and strides
  - PIL-style: shape, strides and suboffsets
- Buffer-related functions
- Old Buffer Protocol

# Object Protocol

`PyObject *Py_NotImplemented`

The `NotImplemented` singleton, used to signal that an operation is not implemented for the given type combination.

`Py_RETURN_NOTIMPLEMENTED`

Properly handle returning `Py_NotImplemented` from within a C function (that is, create a new [strong reference](#) to `NotImplemented` and return it).

`int PyObject_Print(PyObject *o, FILE *fp, int flags)`

Print an object `o`, on file `fp`. Returns `-1` on error. The flags argument is used to enable certain printing options. The only option currently supported is `Py_PRINT_RAW`; if given, the `str()` of the object is written instead of the `repr()`.

`int PyObject_HasAttr(PyObject *o, PyObject *attr_name)`

*Part of the [Stable ABI](#).*

Returns `1` if `o` has the attribute `attr_name`, and `0` otherwise. This is equivalent to the Python expression `hasattr(o, attr_name)`. This function always succeeds.

## Note

Exceptions that occur when this calls `__getattr__()` and `__getattribute__()` methods are silently ignored. For proper error handling, use `PyObject_GetAttr()` instead.

`int PyObject_HasAttrString(PyObject *o, const char *attr_name)`

*Part of the [Stable ABI](#).*

This is the same as `PyObject_HasAttr()`, but `attr_name` is specified as a `const char*` UTF-8 encoded bytes string, rather than a `PyObject*`.

## Note

Exceptions that occur when this calls `__getattr__()` and `__getattribute__()` methods or while creating the temporary `str` object are silently ignored. For proper error handling, use `PyObject_GetAttrString()` instead.

`PyObject *``PyObject_GetAttr(PyObject *o, PyObject *attr_name)`

*Return value:* New reference. Part of the [Stable ABI](#).

Retrieve an attribute named `attr_name` from object `o`. Returns the attribute value on success, or `NULL` on failure. This is the equivalent of the Python expression `o.attr_name`.

`PyObject *``PyObject_GetAttrString(PyObject *o, const char *attr_name)`

*Return value:* New reference. Part of the [Stable ABI](#).

This is the same as `PyObject_GetAttr()`, but `attr_name` is specified as a `const char*` UTF-8 encoded bytes string, rather than a `PyObject*`.

`PyObject *``PyObject_GenericGetAttr(PyObject *o, PyObject *name)`

*Return value:* New reference. Part of the [Stable ABI](#).

Generic attribute getter function that is meant to be put into a type object's `tp_getattro` slot. It looks for a descriptor in the dictionary of classes in the object's MRO as well as an attribute in the object's `__dict__` (if present). As outlined in [Implementing Descriptors](#), data descriptors take preference over instance attributes, while non-data descriptors don't. Otherwise, an `AttributeError` is raised.

`int` `PyObject_SetAttr(PyObject *o, PyObject *attr_name, PyObject`

\*v)

*Part of the [Stable ABI](#).*

Set the value of the attribute named *attr\_name*, for object *o*, to the value *v*. Raise an exception and return `-1` on failure; return `0` on success. This is the equivalent of the Python statement `o.attr_name = v`.

If *v* is `NULL`, the attribute is deleted. This behaviour is deprecated in favour of using [PyObject\\_DelAttr\(\)](#), but there are currently no plans to remove it.

`int PyObject_SetAttrString(PyObject *o, const char *attr_name, PyObject *v)`

*Part of the [Stable ABI](#).*

This is the same as [PyObject\\_SetAttr\(\)](#), but *attr\_name* is specified as a const char\* UTF-8 encoded bytes string, rather than a [PyObject\\*](#).

If *v* is `NULL`, the attribute is deleted, but this feature is deprecated in favour of using [PyObject\\_DelAttrString\(\)](#).

`int PyObject_GenericSetAttr(PyObject *o, PyObject *name, PyObject *value)`

*Part of the [Stable ABI](#).*

Generic attribute setter and deleter function that is meant to be put into a type object's `tp_setattro` slot. It looks for a data descriptor in the dictionary of classes in the object's MRO, and if found it takes preference over setting or deleting the attribute in the instance dictionary. Otherwise, the attribute is set or deleted in the object's `__dict__` (if present). On success, `0` is returned, otherwise an [AttributeError](#) is raised and `-1` is returned.

`int PyObject_DelAttr(PyObject *o, PyObject *attr_name)`

Delete attribute named *attr\_name*, for object *o*. Returns `-1` on failure. This is the equivalent of the Python statement `del o.attr_name`.

`int PyObject_DelAttrString(PyObject *o, const char *attr_name)`

This is the same as `PyObject_DelAttr()`, but `attr_name` is specified as a `const char*` UTF-8 encoded bytes string, rather than a `PyObject*`.

`PyObject *PyObject_GenericGetDict(PyObject *o, void *context)`

*Return value: New reference. Part of the [Stable ABI](#) since version 3.10.*

A generic implementation for the getter of a `__dict__` descriptor. It creates the dictionary if necessary.

This function may also be called to get the `__dict__` of the object `o`. Pass `NULL` for `context` when calling it. Since this function may need to allocate memory for the dictionary, it may be more efficient to call `PyObject_GetAttr()` when accessing an attribute on the object.

On failure, returns `NULL` with an exception set.

*New in version 3.3.*

`int PyObject_GenericSetDict(PyObject *o, PyObject *value, void *context)`

*Part of the [Stable ABI](#) since version 3.7.*

A generic implementation for the setter of a `__dict__` descriptor. This implementation does not allow the dictionary to be deleted.

*New in version 3.3.*

`PyObject **_PyObject_GetDictPtr(PyObject *obj)`

Return a pointer to `__dict__` of the object `obj`. If there is no `__dict__`, return `NULL` without setting an exception.

This function may need to allocate memory for the dictionary, so it may be more efficient to call `PyObject_GetAttr()` when accessing an attribute on the object.

`PyObject *PyObject_RichCompare(PyObject *o1, PyObject *o2, int opid)`

*Return value: New reference. Part of the [Stable ABI](#).*

Compare the values of *o1* and *o2* using the operation specified by *opid*, which must be one of `Py_LT`, `Py_LE`, `Py_EQ`, `Py_NE`, `Py_GT`, or `Py_GE`, corresponding to `<`, `<=`, `==`, `!=`, `>`, or `>=` respectively. This is the equivalent of the Python expression `o1 op o2`, where `op` is the operator corresponding to *opid*. Returns the value of the comparison on success, or `NULL` on failure.

`int PyObject_RichCompareBool(PyObject *o1, PyObject *o2, int opid)`

*Part of the [Stable ABI](#).*

Compare the values of *o1* and *o2* using the operation specified by *opid*, which must be one of `Py_LT`, `Py_LE`, `Py_EQ`, `Py_NE`, `Py_GT`, or `Py_GE`, corresponding to `<`, `<=`, `==`, `!=`, `>`, or `>=` respectively. Returns `-1` on error, `0` if the result is false, `1` otherwise. This is the equivalent of the Python expression `o1 op o2`, where `op` is the operator corresponding to *opid*.

## Note

If *o1* and *o2* are the same object,

`PyObject_RichCompareBool()` will always return `1` for `Py_EQ` and `0` for `Py_NE`.

`PyObject *PyObject_Format(PyObject *obj, PyObject *format_spec)`

*Part of the [Stable ABI](#).*

Format *obj* using *format\_spec*. This is equivalent to the Python expression `format(obj, format_spec)`.

*format\_spec* may be `NULL`. In this case the call is equivalent to `format(obj)`. Returns the formatted string on success, `NULL` on failure.

**PyObject \***PyObject\_Repr(**PyObject \***o)

*Return value:* New reference. Part of the [Stable ABI](#).

Compute a string representation of object *o*. Returns the string representation on success, NULL on failure. This is the equivalent of the Python expression `repr(o)`. Called by the `repr()` built-in function.

*Changed in version 3.4:* This function now includes a debug assertion to help ensure that it does not silently discard an active exception.

**PyObject \***PyObject\_ASCII(**PyObject \***o)

*Return value:* New reference. Part of the [Stable ABI](#).

As `PyObject_Repr()`, compute a string representation of object *o*, but escape the non-ASCII characters in the string returned by `PyObject_Repr()` with `\x`, `\u` or `\U` escapes. This generates a string similar to that returned by `PyObject_Repr()` in Python 2. Called by the `ascii()` built-in function.

**PyObject \***PyObject\_Str(**PyObject \***o)

*Return value:* New reference. Part of the [Stable ABI](#).

Compute a string representation of object *o*. Returns the string representation on success, NULL on failure. This is the equivalent of the Python expression `str(o)`. Called by the `str()` built-in function and, therefore, by the `print()` function.

*Changed in version 3.4:* This function now includes a debug assertion to help ensure that it does not silently discard an active exception.

**PyObject \***PyObject\_Bytes(**PyObject \***o)

*Return value:* New reference. Part of the [Stable ABI](#).

Compute a bytes representation of object *o*. NULL is returned on failure and a bytes object on success. This is equivalent to

the Python expression `bytes(o)`, when `o` is not an integer. Unlike `bytes(o)`, a `TypeError` is raised when `o` is an integer instead of a zero-initialized bytes object.

`int PyObject_IsSubclass(PyObject *derived, PyObject *cls)`

*Part of the [Stable ABI](#).*

Return 1 if the class *derived* is identical to or derived from the class *cls*, otherwise return 0. In case of an error, return -1.

If *cls* is a tuple, the check will be done against every entry in *cls*. The result will be 1 when at least one of the checks returns 1, otherwise it will be 0.

If *cls* has a `__subclasscheck__()` method, it will be called to determine the subclass status as described in [PEP 3119](#) [<https://peps.python.org/pep-3119/>]. Otherwise, *derived* is a subclass of *cls* if it is a direct or indirect subclass, i.e. contained in `cls.__mro__`.

Normally only class objects, i.e. instances of `type` or a derived class, are considered classes. However, objects can override this by having a `__bases__` attribute (which must be a tuple of base classes).

`int PyObject_IsInstance(PyObject *inst, PyObject *cls)`

*Part of the [Stable ABI](#).*

Return 1 if *inst* is an instance of the class *cls* or a subclass of *cls*, or 0 if not. On error, returns -1 and sets an exception.

If *cls* is a tuple, the check will be done against every entry in *cls*. The result will be 1 when at least one of the checks returns 1, otherwise it will be 0.

If *cls* has a `__instancecheck__()` method, it will be called to determine the subclass status as described in [PEP 3119](#) [<https://peps.python.org/pep-3119/>]. Otherwise, *inst* is an instance of *cls* if its class is a subclass of *cls*.

An instance *inst* can override what is considered its class by

having a `__class__` attribute.

An object `cls` can override if it is considered a class, and what its base classes are, by having a `__bases__` attribute (which must be a tuple of base classes).

`Py_hash_t PyObject_Hash(PyObject *o)`

*Part of the [Stable ABI](#).*

Compute and return the hash value of an object `o`. On failure, return `-1`. This is the equivalent of the Python expression `hash(o)`.

*Changed in version 3.2:* The return type is now `Py_hash_t`. This is a signed integer the same size as `Py_ssize_t`.

`Py_hash_t PyObject_HashNotImplemented(PyObject *o)`

*Part of the [Stable ABI](#).*

Set a `TypeError` indicating that `type(o)` is not [hashable](#) and return `-1`. This function receives special treatment when stored in a `tp_hash` slot, allowing a type to explicitly indicate to the interpreter that it is not hashable.

`int PyObject_IsTrue(PyObject *o)`

*Part of the [Stable ABI](#).*

Returns `1` if the object `o` is considered to be true, and `0` otherwise. This is equivalent to the Python expression `not not o`. On failure, return `-1`.

`int PyObject_Not(PyObject *o)`

*Part of the [Stable ABI](#).*

Returns `0` if the object `o` is considered to be true, and `1` otherwise. This is equivalent to the Python expression `not o`. On failure, return `-1`.

`PyObject *PyObject_Type(PyObject *o)`

*Return value:* New reference. *Part of the [Stable ABI](#).*

When `o` is non-NULL, returns a type object corresponding to

the object type of object *o*. On failure, raises **SystemError** and returns `NULL`. This is equivalent to the Python expression `type(o)`. This function creates a new **strong reference** to the return value. There's really no reason to use this function instead of the **Py\_TYPE()** function, which returns a pointer of type `PyObject*`, except when a new **strong reference** is needed.

`int PyObject_TypeCheck(PyObject *o, PyTypeObject *type)`

Return non-zero if the object *o* is of type *type* or a subtype of *type*, and 0 otherwise. Both parameters must be non-NULL.

`Py_ssize_t PyObject_Size(PyObject *o)`

`Py_ssize_t PyObject_Length(PyObject *o)`

*Part of the **Stable ABI**.*

Return the length of object *o*. If the object *o* provides either the sequence and mapping protocols, the sequence length is returned. On error, -1 is returned. This is the equivalent to the Python expression `len(o)`.

`Py_ssize_t PyObject_LengthHint(PyObject *o, Py_ssize_t defaultvalue)`

Return an estimated length for the object *o*. First try to return its actual length, then an estimate using **\_\_length\_hint\_\_()**, and finally return the default value. On error return -1. This is the equivalent to the Python expression `operator.length_hint(o, defaultvalue)`.

*New in version 3.4.*

`PyObject *PyObject_GetItem(PyObject *o, PyObject *key)`

*Return value: New reference. Part of the **Stable ABI**.*

Return element of *o* corresponding to the object *key* or `NULL` on failure. This is the equivalent of the Python expression `o[key]`.

`int PyObject_SetItem(PyObject *o, PyObject *key, PyObject *v)`

*Part of the [Stable ABI](#).*

Map the object *key* to the value *v*. Raise an exception and return `-1` on failure; return `0` on success. This is the equivalent of the Python statement `o[key] = v`. This function *does not* steal a reference to *v*.

`int PyObject_DelItem(PyObject *o, PyObject *key)`

*Part of the [Stable ABI](#).*

Remove the mapping for the object *key* from the object *o*. Return `-1` on failure. This is equivalent to the Python statement `del o[key]`.

`PyObject *PyObject_Dir(PyObject *o)`

*Return value: New reference. Part of the [Stable ABI](#).*

This is equivalent to the Python expression `dir(o)`, returning a (possibly empty) list of strings appropriate for the object argument, or `NULL` if there was an error. If the argument is `NULL`, this is like the Python `dir()`, returning the names of the current locals; in this case, if no execution frame is active then `NULL` is returned but [PyErr\\_Occurred\(\)](#) will return false.

`PyObject *PyObject_GetIter(PyObject *o)`

*Return value: New reference. Part of the [Stable ABI](#).*

This is equivalent to the Python expression `iter(o)`. It returns a new iterator for the object argument, or the object itself if the object is already an iterator. Raises [TypeError](#) and returns `NULL` if the object cannot be iterated.

`PyObject *PyObject_GetAIter(PyObject *o)`

*Return value: New reference. Part of the [Stable ABI](#) since version 3.10.*

This is the equivalent to the Python expression `aiter(o)`. Takes an **AsyncIterable** object and returns an **AsyncIterator** for it. This is typically a new iterator but if the argument is an **AsyncIterator**, this returns itself.

Raises `TypeError` and returns `NULL` if the object cannot be iterated.

*New in version 3.10.*

`void *PyObject_GetTypeData(PyObject *o, PyTypeObject *cls)`

Part of the *Stable ABI* since version 3.12.

Get a pointer to subclass-specific data reserved for *cls*.

The object *o* must be an instance of *cls*, and *cls* must have been created using negative `PyType_Spec.basicsize`. Python does not check this.

On error, set an exception and return `NULL`.

*New in version 3.12.*

`Py_ssize_t PyType_GetTypeDataSize(PyTypeObject *cls)`

Part of the *Stable ABI* since version 3.12.

Return the size of the instance memory space reserved for *cls*, i.e. the size of the memory `PyObject_GetTypeData()` returns.

This may be larger than requested using `-PyType_Spec.basicsize`; it is safe to use this larger size (e.g. with `memset()`).

The type *cls* **must** have been created using negative `PyType_Spec.basicsize`. Python does not check this.

On error, set an exception and return a negative value.

*New in version 3.12.*

`void *PyObject_GetItemData(PyObject *o)`

Get a pointer to per-item data for a class with `Py_TPFLAGS_ITEMS_AT_END`.

On error, set an exception and return `NULL`. `TypeError` is raised if *o* does not have `Py_TPFLAGS_ITEMS_AT_END` set.

*New in version 3.12.*

# Call Protocol

CPython supports two different calling protocols: *tp\_call* and *vectorcall*.

## The *tp\_call* Protocol

Instances of classes that set `tp_call` are callable. The signature of the slot is:

```
PyObject *tp_call(PyObject *callable, PyObject *args, PyObject *
```

A call is made using a tuple for the positional arguments and a dict for the keyword arguments, similarly to `callable(*args, **kwargs)` in Python code. *args* must be non-NULL (use an empty tuple if there are no arguments) but *kwargs* may be *NULL* if there are no keyword arguments.

This convention is not only used by *tp\_call*: `tp_new` and `tp_init` also pass arguments this way.

To call an object, use `PyObject_Call()` or another [call API](#).

## The Vectorcall Protocol

*New in version 3.9.*

The vectorcall protocol was introduced in [PEP 590](#) [<https://peps.python.org/pep-0590/>] as an additional protocol for making calls more efficient.

As rule of thumb, CPython will prefer the vectorcall for internal calls if the callable supports it. However, this is not a hard rule. Additionally, some third-party extensions use *tp\_call* directly (rather than using `PyObject_Call()`). Therefore, a class supporting vectorcall must also implement `tp_call`. Moreover, the callable

must behave the same regardless of which protocol is used. The recommended way to achieve this is by setting `tp_call` to `PyVectorcall_Call()`. This bears repeating:

## Warning

A class supporting vectorcall **must** also implement `tp_call` with the same semantics.

*Changed in version 3.12:* The `Py_TPFLAGS_HAVE_VECTORCALL` flag is now removed from a class when the class's `__call__()` method is reassigned. (This internally sets `tp_call` only, and thus may make it behave differently than the vectorcall function.) In earlier Python versions, vectorcall should only be used with `immutable` or static types.

A class should not implement vectorcall if that would be slower than `tp_call`. For example, if the callee needs to convert the arguments to an args tuple and kwargs dict anyway, then there is no point in implementing vectorcall.

Classes can implement the vectorcall protocol by enabling the `Py_TPFLAGS_HAVE_VECTORCALL` flag and setting `tp_vectorcall_offset` to the offset inside the object structure where a `vectorcallfunc` appears. This is a pointer to a function with the following signature:

```
typedef PyObject *(*vectorcallfunc)(PyObject *callable, PyObject
*const *args, size_t nargsf, PyObject *kwnames)
```

*Part of the [Stable ABI](#) since version 3.12.*

- *callable* is the object being called.
- *args* is a C array consisting of the positional arguments followed by the values of the keyword arguments. This can be `NULL` if there are no arguments.
- *nargsf* is the number of positional arguments plus possibly the `PY_VECTORCALL_ARGUMENTS_OFFSET` flag. To get

the actual number of positional arguments from *nargsf*, use `PyVectorcall_NARGS()`.

- *kwnames* is a tuple containing the names of the keyword arguments;  
in other words, the keys of the *kwargs* dict. These names must be strings (instances of `str` or a subclass) and they must be unique. If there are no keyword arguments, then *kwnames* can instead be *NULL*.

## PY\_VECTORCALL\_ARGUMENTS\_OFFSET

*Part of the [Stable ABI](#) since version 3.12.*

If this flag is set in a vectorcall *nargsf* argument, the callee is allowed to temporarily change `args[-1]`. In other words, *args* points to argument 1 (not 0) in the allocated vector. The callee must restore the value of `args[-1]` before returning.

For `PyObject_VectorcallMethod()`, this flag means instead that `args[0]` may be changed.

Whenever they can do so cheaply (without additional allocation), callers are encouraged to use `PY_VECTORCALL_ARGUMENTS_OFFSET`. Doing so will allow callables such as bound methods to make their onward calls (which include a prepended *self* argument) very efficiently.

To call an object that implements vectorcall, use a [call API](#) function as with any other callable. `PyObject_Vectorcall()` will usually be most efficient.

## Note

In CPython 3.8, the vectorcall API and related functions were available provisionally under names with a leading underscore:

```
_PyObject_Vectorcall,  
_Py_TPFLAGS_HAVE_VECTORCALL,  
_PyObject_VectorcallMethod,  
_PyVectorcall_Function, _PyObject_CallOneArg,  
_PyObject_CallMethodNoArgs,
```

`_PyObject_CallMethodOneArg`. Additionally, `PyObject_VectorcallDict` was available as `_PyObject_FastCallDict`. The old names are still defined as aliases of the new, non-underscored names.

## Recursion Control

When using *tp\_call*, callees do not need to worry about [recursion](#): CPython uses `Py_EnterRecursiveCall()` and `Py_LeaveRecursiveCall()` for calls made using *tp\_call*.

For efficiency, this is not the case for calls done using *vectorcall*: the callee should use *Py\_EnterRecursiveCall* and *Py\_LeaveRecursiveCall* if needed.

## Vectorcall Support API

`Py_ssize_t` `PyVectorcall_NARGS(size_t nargsf)`

*Part of the [Stable ABI](#) since version 3.12.*

Given a vectorcall *nargsf* argument, return the actual number of arguments. Currently equivalent to:

```
(Py_ssize_t) (nargsf & ~PY_VECTORCALL_ARGUMENTS_OFFSET)
```

However, the function `PyVectorcall_NARGS` should be used to allow for future extensions.

*New in version 3.8.*

`vectorcallfunc` `PyVectorcall_Function(PyObject *op)`

If *op* does not support the vectorcall protocol (either because the type does not or because the specific instance does not), return *NULL*. Otherwise, return the vectorcall function pointer stored in *op*. This function never raises an exception.

This is mostly useful to check whether or not *op* supports vectorcall, which can be done by checking `PyVectorcall_Function(op) != NULL`.

*New in version 3.9.*

`PyObject *PyVectorcall_Call(PyObject *callable, PyObject *tuple, PyObject *dict)`

Part of the *Stable ABI* since version 3.12.

Call `callable`'s `vectorcallfunc` with positional and keyword arguments given in a tuple and dict, respectively.

This is a specialized function, intended to be put in the `tp_call` slot or be used in an implementation of `tp_call`. It does not check the `Py_TPFLAGS_HAVE_VECTORCALL` flag and it does not fall back to `tp_call`.

*New in version 3.8.*

## Object Calling API

Various functions are available for calling a Python object. Each converts its arguments to a convention supported by the called object – either *tp\_call* or *vectorcall*. In order to do as little conversion as possible, pick one that best fits the format of data you have available.

The following table summarizes the available functions; please see individual documentation for details.

### ~~Table~~

---

<code>PyObject_Call()</code>
------------------------------

<code>PyObject_VectorcallDict()</code>
----------------------------------------

---

**PyObject \***PyObject\_Call(**PyObject \***callable, **PyObject \***args, **PyObject \***kwargs)

*Return value:* New reference. Part of the [Stable ABI](#).

Call a callable Python object *callable*, with arguments given by the tuple *args*, and named arguments given by the dictionary *kwargs*.

*args* must not be *NULL*; use an empty tuple if no arguments are needed. If no named arguments are needed, *kwargs* can be *NULL*.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

This is the equivalent of the Python expression:  
`callable(*args, **kwargs)`.

**PyObject \***PyObject\_CallNoArgs(**PyObject \***callable)

*Part of the [Stable ABI](#) since version 3.10.*

Call a callable Python object *callable* without any arguments. It is the most efficient way to call a callable Python object without any argument.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

*New in version 3.9.*

**PyObject \***PyObject\_CallOneArg(**PyObject \***callable, **PyObject \***arg)

Call a callable Python object *callable* with exactly 1 positional argument *arg* and no keyword arguments.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

*New in version 3.9.*

**PyObject \***PyObject\_CallObject(**PyObject \***callable, **PyObject \***args)

*Return value:* New reference. Part of the [Stable ABI](#).

Call a callable Python object *callable*, with arguments given by the tuple *args*. If no arguments are needed, then *args* can be *NULL*.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

This is the equivalent of the Python expression:

```
callable(*args).
```

**PyObject \***PyObject\_CallFunction(**PyObject \***callable, const char \*format, ...)

*Return value:* New reference. Part of the [Stable ABI](#).

Call a callable Python object *callable*, with a variable number of C arguments. The C arguments are described using a [Py\\_BuildValue\(\)](#) style format string. The format can be *NULL*, indicating that no arguments are provided.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

This is the equivalent of the Python expression:

```
callable(*args).
```

Note that if you only pass **PyObject \*** args,

[PyObject\\_CallFunctionObjArgs\(\)](#) is a faster alternative.

*Changed in version 3.4:* The type of *format* was changed from `char *`.

**PyObject \***PyObject\_CallMethod(**PyObject \***obj, const char \*name, const char \*format, ...)

*Return value:* New reference. Part of the [Stable ABI](#).

Call the method named *name* of object *obj* with a variable number of C arguments. The C arguments are described by a [Py\\_BuildValue\(\)](#) format string that should produce a

tuple.

The format can be *NULL*, indicating that no arguments are provided.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

This is the equivalent of the Python expression:

```
obj.name(arg1, arg2, ...).
```

Note that if you only pass `PyObject*` args, `PyObject_CallMethodObjArgs()` is a faster alternative.

*Changed in version 3.4:* The types of *name* and *format* were changed from `char *`.

`PyObject *``PyObject_CallFunctionObjArgs(PyObject *callable, ...)`

*Return value:* New reference. Part of the [Stable ABI](#).

Call a callable Python object *callable*, with a variable number of `PyObject*` arguments. The arguments are provided as a variable number of parameters followed by *NULL*.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

This is the equivalent of the Python expression:

```
callable(arg1, arg2, ...).
```

`PyObject *``PyObject_CallMethodObjArgs(PyObject *obj, PyObject *name, ...)`

*Return value:* New reference. Part of the [Stable ABI](#).

Call a method of the Python object *obj*, where the name of the method is given as a Python string object in *name*. It is called with a variable number of `PyObject*` arguments. The arguments are provided as a variable number of parameters followed by *NULL*.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

**PyObject \***PyObject\_CallMethodNoArgs(**PyObject \***obj, **PyObject \***name)

Call a method of the Python object *obj* without arguments, where the name of the method is given as a Python string object in *name*.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

*New in version 3.9.*

**PyObject \***PyObject\_CallMethodOneArg(**PyObject \***obj, **PyObject \***name, **PyObject \***arg)

Call a method of the Python object *obj* with a single positional argument *arg*, where the name of the method is given as a Python string object in *name*.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

*New in version 3.9.*

**PyObject \***PyObject\_Vectorcall(**PyObject \***callable, **PyObject \***const \*args, size\_t nargsf, **PyObject \***kwnames)

Part of the *Stable ABI* since version 3.12.

Call a callable Python object *callable*. The arguments are the same as for **vectorcallfunc**. If *callable* supports **vectorcall**, this directly calls the vectorcall function stored in *callable*.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

*New in version 3.9.*

**PyObject \***PyObject\_VectorcallDict(**PyObject \***callable, **PyObject \***const \*args, size\_t nargsf, **PyObject \***kwdict)

Call *callable* with positional arguments passed exactly as in

the [vectorcall](#) protocol, but with keyword arguments passed as a dictionary *kwdict*. The *args* array contains only the positional arguments.

Regardless of which protocol is used internally, a conversion of arguments needs to be done. Therefore, this function should only be used if the caller already has a dictionary ready to use for the keyword arguments, but not a tuple for the positional arguments.

*New in version 3.9.*

[PyObject](#) \*PyObject\_VectorcallMethod([PyObject](#) \*name, [PyObject](#) \*const \*args, size\_t nargsf, [PyObject](#) \*kwnames)

*Part of the [Stable ABI](#) since version 3.12.*

Call a method using the vectorcall calling convention. The name of the method is given as a Python string *name*. The object whose method is called is *args[0]*, and the *args* array starting at *args[1]* represents the arguments of the call. There must be at least one positional argument. *nargsf* is the number of positional arguments including *args[0]*, plus

[PY\\_VECTORCALL\\_ARGUMENTS\\_OFFSET](#) if the value of *args[0]* may temporarily be changed. Keyword arguments can be passed just like in [PyObject\\_Vectorcall\(\)](#).

If the object has the [Py\\_TPFLAGS\\_METHOD\\_DESCRIPTOR](#) feature, this will call the unbound method object with the full *args* vector as arguments.

Return the result of the call on success, or raise an exception and return *NULL* on failure.

*New in version 3.9.*

## Call Support API

int PyCallable\_Check([PyObject](#) \*o)

*Part of the [Stable ABI](#).*

Determine if the object *o* is callable. Return 1 if the object is

callable and 0 otherwise. This function always succeeds.

# Number Protocol

`int PyNumber_Check(PyObject *o)`

*Part of the [Stable ABI](#).*

Returns 1 if the object *o* provides numeric protocols, and false otherwise. This function always succeeds.

*Changed in version 3.8:* Returns 1 if *o* is an index integer.

`PyObject *PyNumber_Add(PyObject *o1, PyObject *o2)`

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the result of adding *o1* and *o2*, or `NULL` on failure. This is the equivalent of the Python expression `o1 + o2`.

`PyObject *PyNumber_Subtract(PyObject *o1, PyObject *o2)`

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the result of subtracting *o2* from *o1*, or `NULL` on failure. This is the equivalent of the Python expression `o1 - o2`.

`PyObject *PyNumber_Multiply(PyObject *o1, PyObject *o2)`

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the result of multiplying *o1* and *o2*, or `NULL` on failure. This is the equivalent of the Python expression `o1 * o2`.

`PyObject *PyNumber_MatrixMultiply(PyObject *o1, PyObject *o2)`

*Return value: New reference. Part of the [Stable ABI](#) since version 3.7.*

Returns the result of matrix multiplication on *o1* and *o2*, or `NULL` on failure. This is the equivalent of the Python expression `o1 @ o2`.

*New in version 3.5.*

**PyObject \***PyNumber\_FloorDivide(**PyObject \***o1, **PyObject \***o2)

*Return value: New reference. Part of the [Stable ABI](#).*

Return the floor of *o1* divided by *o2*, or `NULL` on failure. This is the equivalent of the Python expression `o1 // o2`.

**PyObject \***PyNumber\_TrueDivide(**PyObject \***o1, **PyObject \***o2)

*Return value: New reference. Part of the [Stable ABI](#).*

Return a reasonable approximation for the mathematical value of *o1* divided by *o2*, or `NULL` on failure. The return value is “approximate” because binary floating point numbers are approximate; it is not possible to represent all real numbers in base two. This function can return a floating point value when passed two integers. This is the equivalent of the Python expression `o1 / o2`.

**PyObject \***PyNumber\_Remainder(**PyObject \***o1, **PyObject \***o2)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the remainder of dividing *o1* by *o2*, or `NULL` on failure. This is the equivalent of the Python expression `o1 % o2`.

**PyObject \***PyNumber\_Divmod(**PyObject \***o1, **PyObject \***o2)

*Return value: New reference. Part of the [Stable ABI](#).*

See the built-in function `divmod()`. Returns `NULL` on failure. This is the equivalent of the Python expression `divmod(o1, o2)`.

**PyObject \***PyNumber\_Power(**PyObject \***o1, **PyObject \***o2, **PyObject \***o3)

*Return value: New reference. Part of the [Stable ABI](#).*

See the built-in function `pow()`. Returns `NULL` on failure. This is the equivalent of the Python expression `pow(o1, o2, o3)`, where *o3* is optional. If *o3* is to be ignored, pass `Py_None` in its place (passing `NULL` for *o3* would cause an illegal memory access).

**PyObject \***PyNumber\_Negative(**PyObject \***o)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the negation of `o` on success, or `NULL` on failure. This is the equivalent of the Python expression `-o`.

**PyObject \***PyNumber\_Positive(PyObject \*o)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns `o` on success, or `NULL` on failure. This is the equivalent of the Python expression `+o`.

**PyObject \***PyNumber\_Absolute(PyObject \*o)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the absolute value of `o`, or `NULL` on failure. This is the equivalent of the Python expression `abs(o)`.

**PyObject \***PyNumber\_Invert(PyObject \*o)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the bitwise negation of `o` on success, or `NULL` on failure. This is the equivalent of the Python expression `~o`.

**PyObject \***PyNumber\_Lshift(PyObject \*o1, PyObject \*o2)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the result of left shifting `o1` by `o2` on success, or `NULL` on failure. This is the equivalent of the Python expression `o1 << o2`.

**PyObject \***PyNumber\_Rshift(PyObject \*o1, PyObject \*o2)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the result of right shifting `o1` by `o2` on success, or `NULL` on failure. This is the equivalent of the Python expression `o1 >> o2`.

**PyObject \***PyNumber\_And(PyObject \*o1, PyObject \*o2)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the “bitwise and” of `o1` and `o2` on success and `NULL` on failure. This is the equivalent of the Python expression `o1 & o2`.

`PyObject *PyNumber_Xor(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the “bitwise exclusive or” of *o1* by *o2* on success, or `NULL` on failure. This is the equivalent of the Python expression `o1 ^ o2`.

`PyObject *PyNumber_Or(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the “bitwise or” of *o1* and *o2* on success, or `NULL` on failure. This is the equivalent of the Python expression `o1 | o2`.

`PyObject *PyNumber_InPlaceAdd(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the result of adding *o1* and *o2*, or `NULL` on failure. The operation is done *in-place* when *o1* supports it. This is the equivalent of the Python statement `o1 += o2`.

`PyObject *PyNumber_InPlaceSubtract(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the result of subtracting *o2* from *o1*, or `NULL` on failure. The operation is done *in-place* when *o1* supports it. This is the equivalent of the Python statement `o1 -= o2`.

`PyObject *PyNumber_InPlaceMultiply(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the result of multiplying *o1* and *o2*, or `NULL` on failure. The operation is done *in-place* when *o1* supports it. This is the equivalent of the Python statement `o1 *= o2`.

`PyObject *PyNumber_InPlaceMatrixMultiply(PyObject *o1,  
PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#) since version 3.7.

Returns the result of matrix multiplication on *o1* and *o2*, or `NULL` on failure. The operation is done *in-place* when *o1* supports it. This is the equivalent of the Python statement `o1`

`@= o2.`

*New in version 3.5.*

**PyObject** \*PyNumber\_InPlaceFloorDivide(PyObject \*o1, PyObject \*o2)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the mathematical floor of dividing *o1* by *o2*, or `NULL` on failure. The operation is done *in-place* when *o1* supports it. This is the equivalent of the Python statement `o1 //= o2`.

**PyObject** \*PyNumber\_InPlaceTrueDivide(PyObject \*o1, PyObject \*o2)

*Return value: New reference. Part of the [Stable ABI](#).*

Return a reasonable approximation for the mathematical value of *o1* divided by *o2*, or `NULL` on failure. The return value is “approximate” because binary floating point numbers are approximate; it is not possible to represent all real numbers in base two. This function can return a floating point value when passed two integers. The operation is done *in-place* when *o1* supports it. This is the equivalent of the Python statement `o1 /= o2`.

**PyObject** \*PyNumber\_InPlaceRemainder(PyObject \*o1, PyObject \*o2)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the remainder of dividing *o1* by *o2*, or `NULL` on failure. The operation is done *in-place* when *o1* supports it. This is the equivalent of the Python statement `o1 %= o2`.

**PyObject** \*PyNumber\_InPlacePower(PyObject \*o1, PyObject \*o2, PyObject \*o3)

*Return value: New reference. Part of the [Stable ABI](#).*

See the built-in function `pow()`. Returns `NULL` on failure. The operation is done *in-place* when *o1* supports it. This is the equivalent of the Python statement `o1 **= o2` when *o3* is `Py_None`, or an in-place variant of `pow(o1, o2, o3)`

otherwise. If `o3` is to be ignored, pass `Py_None` in its place (passing `NULL` for `o3` would cause an illegal memory access).

`PyObject *PyNumber_InPlaceLshift(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the result of left shifting `o1` by `o2` on success, or `NULL` on failure. The operation is done *in-place* when `o1` supports it. This is the equivalent of the Python statement `o1 <<= o2`.

`PyObject *PyNumber_InPlaceRshift(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the result of right shifting `o1` by `o2` on success, or `NULL` on failure. The operation is done *in-place* when `o1` supports it. This is the equivalent of the Python statement `o1 >>= o2`.

`PyObject *PyNumber_InPlaceAnd(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the “bitwise and” of `o1` and `o2` on success and `NULL` on failure. The operation is done *in-place* when `o1` supports it. This is the equivalent of the Python statement `o1 &= o2`.

`PyObject *PyNumber_InPlaceXor(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the “bitwise exclusive or” of `o1` by `o2` on success, or `NULL` on failure. The operation is done *in-place* when `o1` supports it. This is the equivalent of the Python statement `o1 ^= o2`.

`PyObject *PyNumber_InPlaceOr(PyObject *o1, PyObject *o2)`

*Return value:* New reference. Part of the [Stable ABI](#).

Returns the “bitwise or” of `o1` and `o2` on success, or `NULL` on failure. The operation is done *in-place* when `o1` supports it. This is the equivalent of the Python statement `o1 |= o2`.

`PyObject *PyNumber_Long(PyObject *o)`

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the *o* converted to an integer object on success, or `NULL` on failure. This is the equivalent of the Python expression `int(o)`.

[PyObject](#) \*PyNumber\_Float([PyObject](#) \*o)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the *o* converted to a float object on success, or `NULL` on failure. This is the equivalent of the Python expression `float(o)`.

[PyObject](#) \*PyNumber\_Index([PyObject](#) \*o)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the *o* converted to a Python int on success or `NULL` with a [TypeError](#) exception raised on failure.

*Changed in version 3.10:* The result always has exact type [int](#). Previously, the result could have been an instance of a subclass of `int`.

[PyObject](#) \*PyNumber\_ToBase([PyObject](#) \*n, int base)

*Return value: New reference. Part of the [Stable ABI](#).*

Returns the integer *n* converted to base *base* as a string. The *base* argument must be one of 2, 8, 10, or 16. For base 2, 8, or 16, the returned string is prefixed with a base marker of `'0b'`, `'0o'`, or `'0x'`, respectively. If *n* is not a Python int, it is converted with [PyNumber\\_Index\(\)](#) first.

[Py\\_ssize\\_t](#) PyNumber\_AsSsize\_t([PyObject](#) \*o, [PyObject](#) \*exc)

*Part of the [Stable ABI](#).*

Returns *o* converted to a [Py\\_ssize\\_t](#) value if *o* can be interpreted as an integer. If the call fails, an exception is raised and `-1` is returned.

If *o* can be converted to a Python int but the attempt to convert to a [Py\\_ssize\\_t](#) value would raise an [OverflowError](#), then the *exc* argument is the type of exception that will be raised (usually [IndexError](#) or

**OverflowError**). If `exc` is `NULL`, then the exception is cleared and the value is clipped to `PY_SSIZE_T_MIN` for a negative integer or `PY_SSIZE_T_MAX` for a positive integer.

`int PyIndex_Check(PyObject *o)`

*Part of the [Stable ABI](#) since version 3.8.*

Returns `1` if `o` is an index integer (has the `nb_index` slot of the `tp_as_number` structure filled in), and `0` otherwise.

This function always succeeds.

# Sequence Protocol

`int PySequence_Check(PyObject *o)`

*Part of the [Stable ABI](#).*

Return 1 if the object provides the sequence protocol, and 0 otherwise. Note that it returns 1 for Python classes with a `__getitem__()` method, unless they are `dict` subclasses, since in general it is impossible to determine what type of keys the class supports. This function always succeeds.

`Py_ssize_t PySequence_Size(PyObject *o)`

`Py_ssize_t PySequence_Length(PyObject *o)`

*Part of the [Stable ABI](#).*

Returns the number of objects in sequence `o` on success, and `-1` on failure. This is equivalent to the Python expression `len(o)`.

`PyObject *PySequence_Concat(PyObject *o1, PyObject *o2)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return the concatenation of `o1` and `o2` on success, and `NULL` on failure. This is the equivalent of the Python expression `o1 + o2`.

`PyObject *PySequence_Repeat(PyObject *o, Py_ssize_t count)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return the result of repeating sequence object `o` `count` times, or `NULL` on failure. This is the equivalent of the Python expression `o * count`.

`PyObject *PySequence_InPlaceConcat(PyObject *o1, PyObject *o2)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return the concatenation of `o1` and `o2` on success, and `NULL` on failure. The operation is done *in-place* when `o1` supports it.

This is the equivalent of the Python expression `o1 += o2`.

**PyObject \***PySequence\_InPlaceRepeat(**PyObject \****o*, **Py\_ssize\_t** *count*)

*Return value:* New reference. Part of the [Stable ABI](#).

Return the result of repeating sequence object *o* *count* times, or `NULL` on failure. The operation is done *in-place* when *o* supports it. This is the equivalent of the Python expression `o *= count`.

**PyObject \***PySequence\_GetItem(**PyObject \****o*, **Py\_ssize\_t** *i*)

*Return value:* New reference. Part of the [Stable ABI](#).

Return the *i*th element of *o*, or `NULL` on failure. This is the equivalent of the Python expression `o[i]`.

**PyObject \***PySequence\_GetSlice(**PyObject \****o*, **Py\_ssize\_t** *i1*, **Py\_ssize\_t** *i2*)

*Return value:* New reference. Part of the [Stable ABI](#).

Return the slice of sequence object *o* between *i1* and *i2*, or `NULL` on failure. This is the equivalent of the Python expression `o[i1:i2]`.

**int** PySequence\_SetItem(**PyObject \****o*, **Py\_ssize\_t** *i*, **PyObject \****v*)

*Part of the [Stable ABI](#).*

Assign object *v* to the *i*th element of *o*. Raise an exception and return `-1` on failure; return `0` on success. This is the equivalent of the Python statement `o[i] = v`. This function *does not* steal a reference to *v*.

If *v* is `NULL`, the element is deleted, but this feature is deprecated in favour of using [PySequence\\_DelItem\(\)](#).

**int** PySequence\_DelItem(**PyObject \****o*, **Py\_ssize\_t** *i*)

*Part of the [Stable ABI](#).*

Delete the *i*th element of object *o*. Returns `-1` on failure. This is the equivalent of the Python statement `del o[i]`.

`int PySequence_SetSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2, PyObject *v)`

*Part of the [Stable ABI](#).*

Assign the sequence object *v* to the slice in sequence object *o* from *i1* to *i2*. This is the equivalent of the Python statement `o[i1:i2] = v`.

`int PySequence_DelSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2)`

*Part of the [Stable ABI](#).*

Delete the slice in sequence object *o* from *i1* to *i2*. Returns `-1` on failure. This is the equivalent of the Python statement `del o[i1:i2]`.

`Py_ssize_t PySequence_Count(PyObject *o, PyObject *value)`

*Part of the [Stable ABI](#).*

Return the number of occurrences of *value* in *o*, that is, return the number of keys for which `o[key] == value`. On failure, return `-1`. This is equivalent to the Python expression `o.count(value)`.

`int PySequence_Contains(PyObject *o, PyObject *value)`

*Part of the [Stable ABI](#).*

Determine if *o* contains *value*. If an item in *o* is equal to *value*, return `1`, otherwise return `0`. On error, return `-1`. This is equivalent to the Python expression `value in o`.

`Py_ssize_t PySequence_Index(PyObject *o, PyObject *value)`

*Part of the [Stable ABI](#).*

Return the first index *i* for which `o[i] == value`. On error, return `-1`. This is equivalent to the Python expression `o.index(value)`.

`PyObject *PySequence_List(PyObject *o)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a list object with the same contents as the sequence or iterable *o*, or `NULL` on failure. The returned list is guaranteed to be new. This is equivalent to the Python expression

`list(o)`.

**PyObject \***`PySequence_Tuple(PyObject *o)`

*Return value:* New reference. Part of the [Stable ABI](#).

Return a tuple object with the same contents as the sequence or iterable `o`, or `NULL` on failure. If `o` is a tuple, a new reference will be returned, otherwise a tuple will be constructed with the appropriate contents. This is equivalent to the Python expression `tuple(o)`.

**PyObject \***`PySequence_Fast(PyObject *o, const char *m)`

*Return value:* New reference. Part of the [Stable ABI](#).

Return the sequence or iterable `o` as an object usable by the other `PySequence_Fast*` family of functions. If the object is not a sequence or iterable, raises **TypeError** with `m` as the message text. Returns `NULL` on failure.

The `PySequence_Fast*` functions are thus named because they assume `o` is a **PyTupleObject** or a **PyListObject** and access the data fields of `o` directly.

As a CPython implementation detail, if `o` is already a sequence or list, it will be returned.

**Py\_ssize\_t** `PySequence_Fast_GET_SIZE(PyObject *o)`

Returns the length of `o`, assuming that `o` was returned by **PySequence\_Fast()** and that `o` is not `NULL`. The size can also be retrieved by calling **PySequence\_Size()** on `o`, but **PySequence\_Fast\_GET\_SIZE()** is faster because it can assume `o` is a list or tuple.

**PyObject \***`PySequence_Fast_GET_ITEM(PyObject *o, Py_ssize_t i)`

*Return value:* Borrowed reference.

Return the `i`th element of `o`, assuming that `o` was returned by **PySequence\_Fast()**, `o` is not `NULL`, and that `i` is within bounds.

**PyObject \*\***`PySequence_Fast_ITEMS(PyObject *o)`

Return the underlying array of PyObject pointers. Assumes that *o* was returned by `PySequence_Fast()` and *o* is not NULL.

Note, if a list gets resized, the reallocation may relocate the items array. So, only use the underlying array pointer in contexts where the sequence cannot change.

`PyObject *PySequence_ITEM(PyObject *o, Py_ssize_t i)`

*Return value:* New reference.

Return the *i*th element of *o* or NULL on failure. Faster form of `PySequence_GetItem()` but without checking that `PySequence_Check()` on *o* is true and without adjustment for negative indices.

# Mapping Protocol

See also [PyObject\\_GetItem\(\)](#), [PyObject\\_SetItem\(\)](#) and [PyObject\\_DelItem\(\)](#).

int PyMapping\_Check([PyObject](#) \*o)

*Part of the [Stable ABI](#).*

Return 1 if the object provides the mapping protocol or supports slicing, and 0 otherwise. Note that it returns 1 for Python classes with a [\\_\\_getitem\\_\\_\(\)](#) method, since in general it is impossible to determine what type of keys the class supports. This function always succeeds.

[Py\\_ssize\\_t](#) PyMapping\_Size([PyObject](#) \*o)

[Py\\_ssize\\_t](#) PyMapping\_Length([PyObject](#) \*o)

*Part of the [Stable ABI](#).*

Returns the number of keys in object o on success, and -1 on failure. This is equivalent to the Python expression `len(o)`.

[PyObject](#) \*PyMapping\_GetItemString([PyObject](#) \*o, const char \*key)

*Return value: New reference. Part of the [Stable ABI](#).*

This is the same as [PyObject\\_GetItem\(\)](#), but key is specified as a const char\* UTF-8 encoded bytes string, rather than a [PyObject](#)\*.

int PyMapping\_SetItemString([PyObject](#) \*o, const char \*key,  
[PyObject](#) \*v)

*Part of the [Stable ABI](#).*

This is the same as [PyObject\\_SetItem\(\)](#), but key is specified as a const char\* UTF-8 encoded bytes string, rather than a [PyObject](#)\*.

int PyMapping\_DelItem([PyObject](#) \*o, [PyObject](#) \*key)

This is an alias of `PyObject_DelItem()`.

`int PyMapping_DelItemString(PyObject *o, const char *key)`

This is the same as `PyObject_DelItem()`, but `key` is specified as a `const char*` UTF-8 encoded bytes string, rather than a `PyObject*`.

`int PyMapping_HasKey(PyObject *o, PyObject *key)`

*Part of the [Stable ABI](#).*

Return `1` if the mapping object has the key `key` and `0` otherwise. This is equivalent to the Python expression `key in o`. This function always succeeds.

### Note

Exceptions which occur when this calls `__getitem__()` method are silently ignored. For proper error handling, use `PyObject_GetItem()` instead.

`int PyMapping_HasKeyString(PyObject *o, const char *key)`

*Part of the [Stable ABI](#).*

This is the same as `PyMapping_HasKey()`, but `key` is specified as a `const char*` UTF-8 encoded bytes string, rather than a `PyObject*`.

### Note

Exceptions that occur when this calls `__getitem__()` method or while creating the temporary `str` object are silently ignored. For proper error handling, use `PyMapping_GetItemString()` instead.

`PyObject *PyMapping_Keys(PyObject *o)`

*Return value: New reference. Part of the [Stable ABI](#).*

On success, return a list of the keys in object `o`. On failure,

return NULL.

*Changed in version 3.7:* Previously, the function returned a list or a tuple.

**PyObject \***PyMapping\_Values(**PyObject \***o)

*Return value:* New reference. Part of the [Stable ABI](#).

On success, return a list of the values in object o. On failure, return NULL.

*Changed in version 3.7:* Previously, the function returned a list or a tuple.

**PyObject \***PyMapping\_Items(**PyObject \***o)

*Return value:* New reference. Part of the [Stable ABI](#).

On success, return a list of the items in object o, where each item is a tuple containing a key-value pair. On failure, return NULL.

*Changed in version 3.7:* Previously, the function returned a list or a tuple.

# Iterator Protocol

There are two functions specifically for working with iterators.

`int PyIter_Check(PyObject *o)`

*Part of the [Stable ABI](#) since version 3.8.*

Return non-zero if the object *o* can be safely passed to [PyIter\\_Next\(\)](#), and 0 otherwise. This function always succeeds.

`int PyAlter_Check(PyObject *o)`

*Part of the [Stable ABI](#) since version 3.10.*

Return non-zero if the object *o* provides the **AsyncIterator** protocol, and 0 otherwise. This function always succeeds.

*New in version 3.10.*

`PyObject *PyIter_Next(PyObject *o)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return the next value from the iterator *o*. The object must be an iterator according to [PyIter\\_Check\(\)](#) (it is up to the caller to check this). If there are no remaining values, returns NULL with no exception set. If an error occurs while retrieving the item, returns NULL and passes along the exception.

To write a loop which iterates over an iterator, the C code should look something like this:

```
PyObject *iterator = PyObject_GetIter(obj);
PyObject *item;

if (iterator == NULL) {
```

```

        /* propagate error */
    }

    while ((item = PyIter_Next(iterator))) {
        /* do something with item */
        ...
        /* release reference when done */
        Py_DECREF(item);
    }

    Py_DECREF(iterator);

    if (PyErr_Occurred()) {
        /* propagate error */
    }
    else {
        /* continue doing useful work */
    }

```

type PySendResult

The enum value used to represent different results of [PyIter\\_Send\(\)](#).

*New in version 3.10.*

[PySendResult](#) PyIter\_Send([PyObject](#) \*iter, [PyObject](#) \*arg, [PyObject](#) \*\*presult)

*Part of the [Stable ABI](#) since version 3.10.*

Sends the *arg* value into the iterator *iter*. Returns:

- PYGEN\_RETURN if iterator returns. Return value is returned via *presult*.
- PYGEN\_NEXT if iterator yields. Yielded value is returned via *presult*.
- PYGEN\_ERROR if iterator has raised an exception. *presult* is set to NULL.

*New in version 3.10.*

# Buffer Protocol

Certain objects available in Python wrap access to an underlying memory array or *buffer*. Such objects include the built-in `bytes` and `bytearray`, and some extension types like `array.array`. Third-party libraries may define their own types for special purposes, such as image processing or numeric analysis.

While each of these types have their own semantics, they share the common characteristic of being backed by a possibly large memory buffer. It is then desirable, in some situations, to access that buffer directly and without intermediate copying.

Python provides such a facility at the C level in the form of the `buffer protocol`. This protocol has two sides:

- on the producer side, a type can export a “buffer interface” which allows objects of that type to expose information about their underlying buffer. This interface is described in the section `Buffer Object Structures`;
- on the consumer side, several means are available to obtain a pointer to the raw underlying data of an object (for example a method parameter).

Simple objects such as `bytes` and `bytearray` expose their underlying buffer in byte-oriented form. Other forms are possible; for example, the elements exposed by an `array.array` can be multi-byte values.

An example consumer of the buffer interface is the `write()` method of file objects: any object that can export a series of bytes through the buffer interface can be written to a file. While `write()` only needs read-only access to the internal contents of the object passed to it, other methods such as `readinto()` need write access to the contents of their argument. The buffer interface allows objects to selectively allow or reject exporting of read-write and read-only buffers.

There are two ways for a consumer of the buffer interface to acquire a buffer over a target object:

- call `PyObject_GetBuffer()` with the right parameters;
- call `PyArg_ParseTuple()` (or one of its siblings) with one of the `y*`, `w*` or `s*` [format codes](#).

In both cases, `PyBuffer_Release()` must be called when the buffer isn't needed anymore. Failure to do so could lead to various issues such as resource leaks.

## Buffer structure

Buffer structures (or simply “buffers”) are useful as a way to expose the binary data from another object to the Python programmer. They can also be used as a zero-copy slicing mechanism. Using their ability to reference a block of memory, it is possible to expose any data to the Python programmer quite easily. The memory could be a large, constant array in a C extension, it could be a raw block of memory for manipulation before passing to an operating system library, or it could be used to pass around structured data in its native, in-memory format.

Contrary to most data types exposed by the Python interpreter, buffers are not `PyObject` pointers but rather simple C structures. This allows them to be created and copied very simply. When a generic wrapper around a buffer is needed, a [memoryview](#) object can be created.

For short instructions how to write an exporting object, see [Buffer Object Structures](#). For obtaining a buffer, see `PyObject_GetBuffer()`.

type `Py_buffer`

*Part of the [Stable ABI](#) (including all members) since version 3.11.*

`void *buf`

A pointer to the start of the logical structure described by the buffer fields. This can be any location within the underlying physical memory block of the exporter. For

example, with negative **strides** the value may point to the end of the memory block.

For **contiguous** arrays, the value points to the beginning of the memory block.

### **PyObject \***obj

A new reference to the exporting object. The reference is owned by the consumer and automatically released (i.e. reference count decremented) and set to `NULL` by **PyBuffer\_Release()**. The field is the equivalent of the return value of any standard C-API function.

As a special case, for *temporary* buffers that are wrapped by **PyMemoryView\_FromBuffer()** or **PyBuffer\_FillInfo()** this field is `NULL`. In general, exporting objects **MUST NOT** use this scheme.

### **Py\_ssize\_t** len

`product(shape) * itemsize`. For contiguous arrays, this is the length of the underlying memory block. For non-contiguous arrays, it is the length that the logical structure would have if it were copied to a contiguous representation.

Accessing `((char *)buf)[0]` up to `((char *)buf)[len-1]` is only valid if the buffer has been obtained by a request that guarantees contiguity. In most cases such a request will be **PyBUF\_SIMPLE** or **PyBUF\_WRITABLE**.

### **int** readonly

An indicator of whether the buffer is read-only. This field is controlled by the **PyBUF\_WRITABLE** flag.

### **Py\_ssize\_t** itemsize

Item size in bytes of a single element. Same as the value of **struct.calcsize()** called on non-NULL **format** values.

Important exception: If a consumer requests a buffer without the `PyBUF_FORMAT` flag, `format` will be set to `NULL`, but `itemsz` still has the value for the original format.

If `shape` is present, the equality `product(shape) * itemsz == len` still holds and the consumer can use `itemsz` to navigate the buffer.

If `shape` is `NULL` as a result of a `PyBUF_SIMPLE` or a `PyBUF_WRITABLE` request, the consumer must disregard `itemsz` and assume `itemsz == 1`.

`const char *format`

A `NUL` terminated string in `struct` module style syntax describing the contents of a single item. If this is `NULL`, `"B"` (unsigned bytes) is assumed.

This field is controlled by the `PyBUF_FORMAT` flag.

`int ndim`

The number of dimensions the memory represents as an n-dimensional array. If it is `0`, `buf` points to a single item representing a scalar. In this case, `shape`, `strides` and `suboffsets` MUST be `NULL`. The maximum number of dimensions is given by `PyBUF_MAX_NDIM`.

`Py_ssize_t *shape`

An array of `Py_ssize_t` of length `ndim` indicating the shape of the memory as an n-dimensional array. Note that `shape[0] * ... * shape[ndim-1] * itemsz` MUST be equal to `len`.

Shape values are restricted to `shape[n] >= 0`. The case `shape[n] == 0` requires special attention. See [complex arrays](#) for further information.

The shape array is read-only for the consumer.

### `Py_ssize_t *strides`

An array of `Py_ssize_t` of length `ndim` giving the number of bytes to skip to get to a new element in each dimension.

Stride values can be any integer. For regular arrays, strides are usually positive, but a consumer MUST be able to handle the case `strides[n] <= 0`. See [complex arrays](#) for further information.

The strides array is read-only for the consumer.

### `Py_ssize_t *suboffsets`

An array of `Py_ssize_t` of length `ndim`. If `suboffsets[n] >= 0`, the values stored along the `n`th dimension are pointers and the suboffset value dictates how many bytes to add to each pointer after de-referencing. A suboffset value that is negative indicates that no de-referencing should occur (striding in a contiguous memory block).

If all suboffsets are negative (i.e. no de-referencing is needed), then this field must be `NULL` (the default value).

This type of array representation is used by the Python Imaging Library (PIL). See [complex arrays](#) for further information how to access elements of such an array.

The suboffsets array is read-only for the consumer.

### `void *internal`

This is for use internally by the exporting object. For example, this might be re-cast as an integer by the exporter and used to store flags about whether or not the shape, strides, and suboffsets arrays must be freed when the buffer is released. The consumer MUST NOT alter this value.

Constants:

## PyBUF\_MAX\_NDIM

The maximum number of dimensions the memory represents. Exporters **MUST** respect this limit, consumers of multi-dimensional buffers **SHOULD** be able to handle up to **PyBUF\_MAX\_NDIM** dimensions. Currently set to 64.

## Buffer request types

Buffers are usually obtained by sending a buffer request to an exporting object via `PyObject_GetBuffer()`. Since the complexity of the logical structure of the memory can vary drastically, the consumer uses the *flags* argument to specify the exact buffer type it can handle.

All `Py_buffer` fields are unambiguously defined by the request type.

### request-independent fields

The following fields are not influenced by *flags* and must always be filled in with the correct values: `obj`, `buf`, `len`, `itemsiz`, `ndim`.

### readonly, format

#### PyBUF\_WRITABLE

Controls the `readonly` field. If set, the exporter **MUST** provide a writable buffer or else report failure. Otherwise, the exporter **MAY** provide either a read-only or writable buffer, but the choice **MUST** be consistent for all consumers.

#### PyBUF\_FORMAT

Controls the `format` field. If set, this field **MUST** be filled in correctly. Otherwise, this field **MUST** be `NULL`.

`PyBUF_WRITABLE` can be |'d to any of the flags in the next section. Since `PyBUF_SIMPLE` is defined as 0, `PyBUF_WRITABLE` can be used as a stand-alone flag to request a simple writable buffer.

`PyBUF_FORMAT` can be |'d to any of the flags except `PyBUF_SIMPLE`. The latter already implies format `B` (unsigned bytes).

## shape, strides, suboffsets

The flags that control the logical structure of the memory are listed in decreasing order of complexity. Note that each flag contains all bits of the flags below it.

Flags
<code>PyBUF_INDIRECT</code>
<code>PyBUF_STRIDES</code>
<code>PyBUF_ND</code>
<code>PyBUF_SIMPLE</code>

## contiguity requests

C or Fortran `contiguity` can be explicitly requested, with and without stride information. Without stride information, the buffer must be C-contiguous.

Flags
<code>PyBUF_C_CONTIGUOUS</code>
<code>PyBUF_F_CONTIGUOUS</code>
<code>PyBUF_ANY_CONTIGUOUS</code>
<code>PyBUF_ND</code>

## compound requests

All possible requests are fully defined by some combination of the flags in the previous section. For convenience, the buffer protocol provides frequently used combinations as single flags.

In the following table *U* stands for undefined contiguity. The consumer would have to call `PyBuffer_IsContiguous()` to

determine contiguity.

<del>#if 0</del>	<del>64K - 16K bytes</del>
<del>USHORT</del>	<del>USHORT_NULL</del>
<del>USHORT</del>	<del>USHORT_NULL_RO</del>
<del>USHORT</del>	<del>USHORT_RECORDS</del>
<del>USHORT</del>	<del>USHORT_RECORDS_RO</del>
<del>USHORT</del>	<del>USHORT_STRIDED</del>
<del>USHORT</del>	<del>USHORT_STRIDED_RO</del>
<del>USHORT</del>	<del>USHORT_CONTIG</del>
<del>USHORT</del>	<del>USHORT_CONTIG_RO</del>

## Complex arrays

## NumPy-style: shape and strides

The logical structure of NumPy-style arrays is defined by `itemsize`, `ndim`, `shape` and `strides`.

If `ndim == 0`, the memory location pointed to by `buf` is interpreted as a scalar of size `itemsizes`. In that case, both `shape` and `strides` are `NULL`.

If `strides` is `NULL`, the array is interpreted as a standard n-dimensional C-array. Otherwise, the consumer must access an n-dimensional array as follows:

```
ptr = (char *)buf + indices[0] * strides[0] + ... + indices[n-1] * strides[n-1];
item = *((typeof(item) *)ptr);
```

As noted above, `buf` can point to any location within the actual memory block. An exporter can check the validity of a buffer with this function:

```
def verify_structure(memlen, itemsize, ndim, shape, strides):
    """Verify that the parameters represent a valid array
    and compute the bounds of the allocated memory:
    char *mem: start of the physical memory block
    memlen: length of the physical memory block
    offset: (char *)buf - mem
```

```

"""
if offset % itemsize:
    return False
if offset < 0 or offset+itemsize > memlen:
    return False
if any(v % itemsize for v in strides):
    return False

if ndim <= 0:
    return ndim == 0 and not shape and not strides
if 0 in shape:
    return True

imin = sum(strides[j]*(shape[j]-1) for j in range(no
            if strides[j] <= 0)
imax = sum(strides[j]*(shape[j]-1) for j in range(no
            if strides[j] > 0)

return 0 <= offset+imin and offset+imax+itemsize <=

```

## PIL-style: shape, strides and suboffsets

In addition to the regular items, PIL-style arrays can contain pointers that must be followed in order to get to the next element in a dimension. For example, the regular three-dimensional C-array `char v[2][2][3]` can also be viewed as an array of 2 pointers to 2 two-dimensional arrays: `char (*v[2])[2][3]`. In suboffsets representation, those two pointers can be embedded at the start of [buf](#), pointing to two `char x[2][3]` arrays that can be located anywhere in memory.

Here is a function that returns a pointer to the element in an N-D array pointed to by an N-dimensional index when there are both non-NULL strides and suboffsets:

```

void *get_item_pointer(int ndim, void *buf, Py_ssize_t *
                        Py_ssize_t *suboffsets, Py_ssize_t
char *pointer = (char*)buf;
int i;

```

```

    for (i = 0; i < ndim; i++) {
        pointer += strides[i] * indices[i];
        if (suboffsets[i] >= 0 ) {
            pointer = *((char**)pointer) + suboffsets[i]
        }
    }
    return (void*)pointer;
}

```

## Buffer-related functions

`int PyObject_CheckBuffer(PyObject *obj)`

*Part of the [Stable ABI](#) since version 3.11.*

Return 1 if *obj* supports the buffer interface otherwise 0.

When 1 is returned, it doesn't guarantee that

[PyObject\\_GetBuffer\(\)](#) will succeed. This function always succeeds.

`int PyObject_GetBuffer(PyObject *exporter, Py_buffer *view, int flags)`

*Part of the [Stable ABI](#) since version 3.11.*

Send a request to *exporter* to fill in *view* as specified by *flags*. If the exporter cannot provide a buffer of the exact type, it MUST raise [BufferError](#), set *view->obj* to NULL and return -1.

On success, fill in *view*, set *view->obj* to a new reference to *exporter* and return 0. In the case of chained buffer providers that redirect requests to a single object, *view->obj* MAY refer to this object instead of *exporter* (See [Buffer Object Structures](#)).

Successful calls to [PyObject\\_GetBuffer\(\)](#) must be paired with calls to [PyBuffer\\_Release\(\)](#), similar to `malloc()` and `free()`. Thus, after the consumer is done with the buffer, [PyBuffer\\_Release\(\)](#) must be called exactly once.

`void PyBuffer_Release(Py_buffer *view)`

*Part of the [Stable ABI](#) since version 3.11.*

Release the buffer view and release the [strong reference](#) (i.e. decrement the reference count) to the view's supporting object, `view->obj`. This function MUST be called when the buffer is no longer being used, otherwise reference leaks may occur.

It is an error to call this function on a buffer that was not obtained via [PyObject\\_GetBuffer\(\)](#).

[Py\\_ssize\\_t](#) PyBuffer\_SizeFromFormat(const char \*format)

*Part of the [Stable ABI](#) since version 3.11.*

Return the implied [itemsizes](#) from [format](#). On error, raise an exception and return -1.

*New in version 3.9.*

int PyBuffer\_IsContiguous(const [Py\\_buffer](#) \*view, char order)

*Part of the [Stable ABI](#) since version 3.11.*

Return 1 if the memory defined by the *view* is C-style (*order* is 'C') or Fortran-style (*order* is 'F') [contiguous](#) or either one (*order* is 'A'). Return 0 otherwise. This function always succeeds.

void \*PyBuffer\_GetPointer(const [Py\\_buffer](#) \*view, const [Py\\_ssize\\_t](#) \*indices)

*Part of the [Stable ABI](#) since version 3.11.*

Get the memory area pointed to by the *indices* inside the given *view*. *indices* must point to an array of `view->ndim` indices.

int PyBuffer\_FromContiguous(const [Py\\_buffer](#) \*view, const void \*buf, [Py\\_ssize\\_t](#) len, char fort)

*Part of the [Stable ABI](#) since version 3.11.*

Copy contiguous *len* bytes from *buf* to *view*. *fort* can be 'C' or 'F' (for C-style or Fortran-style ordering). 0 is returned on success, -1 on error.

int PyBuffer\_ToContiguous(void \*buf, const [Py\\_buffer](#) \*src, [Py\\_ssize\\_t](#) len, char order)

*Part of the [Stable ABI](#) since version 3.11.*

Copy *len* bytes from *src* to its contiguous representation in *buf*. *order* can be 'C' or 'F' or 'A' (for C-style or Fortran-style ordering or either one). 0 is returned on success, -1 on error.

This function fails if *len* != *src*->*len*.

int PyObject\_CopyData([PyObject](#) \*dest, [PyObject](#) \*src)

*Part of the [Stable ABI](#) since version 3.11.*

Copy data from *src* to *dest* buffer. Can convert between C-style and or Fortran-style buffers.

0 is returned on success, -1 on error.

void PyBuffer\_FillContiguousStrides(int ndims, [Py\\_ssize\\_t](#) \*shape, [Py\\_ssize\\_t](#) \*strides, int itemsize, char order)

*Part of the [Stable ABI](#) since version 3.11.*

Fill the *strides* array with byte-strides of a [contiguous](#) (C-style if *order* is 'C' or Fortran-style if *order* is 'F') array of the given shape with the given number of bytes per element.

int PyBuffer\_FillInfo([Py\\_buffer](#) \*view, [PyObject](#) \*exporter, void \*buf, [Py\\_ssize\\_t](#) len, int readonly, int flags)

*Part of the [Stable ABI](#) since version 3.11.*

Handle buffer requests for an exporter that wants to expose *buf* of size *len* with writability set according to *readonly*. *buf* is interpreted as a sequence of unsigned bytes.

The *flags* argument indicates the request type. This function always fills in *view* as specified by flags, unless *buf* has been designated as read-only and [PyBUF\\_WRITABLE](#) is set in *flags*.

On success, set *view*->*obj* to a new reference to *exporter* and return 0. Otherwise, raise [BufferError](#), set *view*->*obj* to NULL and return -1;

If this function is used as part of a [getbufferproc](#), *exporter* MUST be set to the exporting object and *flags* must be passed unmodified. Otherwise, *exporter* MUST be `NULL`.

# Old Buffer Protocol

*Deprecated since version 3.0.*

These functions were part of the “old buffer protocol” API in Python 2. In Python 3, this protocol doesn’t exist anymore but the functions are still exposed to ease porting 2.x code. They act as a compatibility wrapper around the [new buffer protocol](#), but they don’t give you control over the lifetime of the resources acquired when a buffer is exported.

Therefore, it is recommended that you call [PyObject\\_GetBuffer\(\)](#) (or the `y*` or `w*` [format codes](#) with the [PyArg\\_ParseTuple\(\)](#) family of functions) to get a buffer view over an object, and [PyBuffer\\_Release\(\)](#) when the buffer view can be released.

```
int PyObject_AsCharBuffer(PyObject *obj, const char **buffer,  
Py\_ssize\_t *buffer_len)
```

*Part of the [Stable ABI](#).*

Returns a pointer to a read-only memory location usable as character-based input. The *obj* argument must support the single-segment character buffer interface. On success, returns 0, sets *buffer* to the memory location and *buffer\_len* to the buffer length. Returns -1 and sets a [TypeError](#) on error.

```
int PyObject_AsReadBuffer(PyObject *obj, const void **buffer,  
Py\_ssize\_t *buffer_len)
```

*Part of the [Stable ABI](#).*

Returns a pointer to a read-only memory location containing arbitrary data. The *obj* argument must support the single-segment readable buffer interface. On success, returns 0, sets *buffer* to the memory location and *buffer\_len* to the buffer length. Returns -1 and sets a [TypeError](#) on error.

int PyObject\_CheckReadBuffer(PyObject \*o)

*Part of the [Stable ABI](#).*

Returns 1 if *o* supports the single-segment readable buffer interface. Otherwise returns 0. This function always succeeds.

Note that this function tries to get and release a buffer, and exceptions which occur while calling corresponding functions will get suppressed. To get error reporting use [PyObject\\_GetBuffer\(\)](#) instead.

int PyObject\_AsWriteBuffer(PyObject \*obj, void \*\*buffer, Py\_ssize\_t \*buffer\_len)

*Part of the [Stable ABI](#).*

Returns a pointer to a writable memory location. The *obj* argument must support the single-segment, character buffer interface. On success, returns 0, sets *buffer* to the memory location and *buffer\_len* to the buffer length. Returns -1 and sets a [TypeError](#) on error.

# Concrete Objects Layer

The functions in this chapter are specific to certain Python object types. Passing them an object of the wrong type is not a good idea; if you receive an object from a Python program and you are not sure that it has the right type, you must perform a type check first; for example, to check that an object is a dictionary, use `PyDict_Check()`. The chapter is structured like the “family tree” of Python object types.

## Warning

While the functions described in this chapter carefully check the type of the objects which are passed in, many of them do not check for `NULL` being passed instead of a valid object. Allowing `NULL` to be passed in can cause memory access violations and immediate termination of the interpreter.

## Fundamental Objects

This section describes Python type objects and the singleton object `None`.

- [Type Objects](#)

# Type Objects

type PyObject

*Part of the [Limited API](#) (as an opaque struct).*

The C structure of the objects used to describe built-in types.

[PyObject](#) PyType\_Type

*Part of the [Stable ABI](#).*

This is the type object for type objects; it is the same object as [type](#) in the Python layer.

int PyType\_Check([PyObject](#) \*o)

Return non-zero if the object *o* is a type object, including instances of types derived from the standard type object. Return 0 in all other cases. This function always succeeds.

int PyType\_CheckExact([PyObject](#) \*o)

Return non-zero if the object *o* is a type object, but not a subtype of the standard type object. Return 0 in all other cases. This function always succeeds.

unsigned int PyType\_ClearCache()

*Part of the [Stable ABI](#).*

Clear the internal lookup cache. Return the current version tag.

unsigned long PyType\_GetFlags([PyTypeObject](#) \*type)

*Part of the [Stable ABI](#).*

Return the [tp\\_flags](#) member of *type*. This function is primarily meant for use with `PY_LIMITED_API`; the individual flag bits are guaranteed to be stable across Python releases, but access to [tp\\_flags](#) itself is not part of the [limited API](#).

*New in version 3.2.*

*Changed in version 3.4:* The return type is now `unsigned long` rather than `long`.

`PyObject *``PyType_GetDict(PyTypeObject *type)`

Return the type object's internal namespace, which is otherwise only exposed via a read-only proxy (`cls.__dict__`). This is a replacement for accessing `tp_dict` directly. The returned dictionary must be treated as read-only.

This function is meant for specific embedding and language-binding cases, where direct access to the dict is necessary and indirect access (e.g. via the proxy or `PyObject_GetAttr()`) isn't adequate.

Extension modules should continue to use `tp_dict`, directly or indirectly, when setting up their own types.

*New in version 3.12.*

`void` `PyType_Modified(PyTypeObject *type)`

*Part of the [Stable ABI](#).*

Invalidate the internal lookup cache for the type and all of its subtypes. This function must be called after any manual modification of the attributes or base classes of the type.

`int` `PyType_AddWatcher(PyType_WatchCallback callback)`

Register *callback* as a type watcher. Return a non-negative integer ID which must be passed to future calls to `PyType_Watch()`. In case of error (e.g. no more watcher IDs available), return `-1` and set an exception.

*New in version 3.12.*

`int` `PyType_ClearWatcher(int watcher_id)`

Clear watcher identified by *watcher\_id* (previously returned from `PyType_AddWatcher()`). Return `0` on success, `-1` on

error (e.g. if `watcher_id` was never registered.)

An extension should never call `PyType_ClearWatcher` with a `watcher_id` that was not returned to it by a previous call to `PyType_AddWatcher()`.

*New in version 3.12.*

`int PyType_Watch(int watcher_id, PyObject *type)`

Mark `type` as watched. The callback granted `watcher_id` by `PyType_AddWatcher()` will be called whenever `PyType_Modified()` reports a change to `type`. (The callback may be called only once for a series of consecutive modifications to `type`, if `_PyType_Lookup()` is not called on `type` between the modifications; this is an implementation detail and subject to change.)

An extension should never call `PyType_Watch` with a `watcher_id` that was not returned to it by a previous call to `PyType_AddWatcher()`.

*New in version 3.12.*

`typedef int (*PyType_WatchCallback)(PyObject *type)`

Type of a type-watcher callback function.

The callback must not modify `type` or cause `PyType_Modified()` to be called on `type` or any type in its MRO; violating this rule could cause infinite recursion.

*New in version 3.12.*

`int PyType_HasFeature(PyTypeObject *o, int feature)`

Return non-zero if the type object `o` sets the feature `feature`. Type features are denoted by single bit flags.

`int PyType_IS_GC(PyTypeObject *o)`

Return true if the type object includes support for the cycle detector; this tests the type flag `Py_TPFLAGS_HAVE_GC`.

int PyType\_IsSubtype(PyTypeObject \*a, PyTypeObject \*b)

*Part of the [Stable ABI](#).*

Return true if *a* is a subtype of *b*.

This function only checks for actual subtypes, which means that `__subclasscheck__()` is not called on *b*. Call `PyObject_IsSubclass()` to do the same check that `issubclass()` would do.

PyObject \*PyType\_GenericAlloc(PyTypeObject \*type, Py\_ssize\_t nitems)

*Return value: New reference. Part of the [Stable ABI](#).*

Generic handler for the `tp_alloc` slot of a type object. Use Python's default memory allocation mechanism to allocate a new instance and initialize all its contents to `NULL`.

PyObject \*PyType\_GenericNew(PyTypeObject \*type, PyObject \*args, PyObject \*kwargs)

*Return value: New reference. Part of the [Stable ABI](#).*

Generic handler for the `tp_new` slot of a type object. Create a new instance using the type's `tp_alloc` slot.

int PyType\_Ready(PyTypeObject \*type)

*Part of the [Stable ABI](#).*

Finalize a type object. This should be called on all type objects to finish their initialization. This function is responsible for adding inherited slots from a type's base class. Return `0` on success, or return `-1` and sets an exception on error.

## Note

If some of the base classes implements the GC protocol and the provided type does not include the `Py_TPFLAGS_HAVE_GC` in its flags, then the GC protocol will be automatically implemented from its parents. On the contrary, if the type being created does include `Py_TPFLAGS_HAVE_GC` in its flags then it **must**

implement the GC protocol itself by at least implementing the `tp_traverse` handle.

`PyObject *PyType_GetName(PyTypeObject *type)`

*Return value:* New reference. Part of the [Stable ABI](#) since version 3.11.

Return the type's name. Equivalent to getting the type's `__name__` attribute.

*New in version 3.11.*

`PyObject *PyType_GetQualName(PyTypeObject *type)`

*Return value:* New reference. Part of the [Stable ABI](#) since version 3.11.

Return the type's qualified name. Equivalent to getting the type's `__qualname__` attribute.

*New in version 3.11.*

`void *PyType_GetSlot(PyTypeObject *type, int slot)`

*Part of the [Stable ABI](#) since version 3.4.*

Return the function pointer stored in the given slot. If the result is `NULL`, this indicates that either the slot is `NULL`, or that the function was called with invalid parameters. Callers will typically cast the result pointer into the appropriate function type.

See [PyType\\_Slot.slot](#) for possible values of the *slot* argument.

*New in version 3.4.*

*Changed in version 3.10:* `PyType_GetSlot()` can now accept all types. Previously, it was limited to [heap types](#).

`PyObject *PyType_GetModule(PyTypeObject *type)`

*Part of the [Stable ABI](#) since version 3.10.*

Return the module object associated with the given type when the type was created using

`PyType_FromModuleAndSpec()`.

If no module is associated with the given type, sets

`TypeError` and returns `NULL`.

This function is usually used to get the module in which a method is defined. Note that in such a method,

`PyType_GetModule(Py_TYPE(self))` may not return the intended result. `Py_TYPE(self)` may be a *subclass* of the intended class, and subclasses are not necessarily defined in the same module as their superclass. See `PyCMethod` to get the class that defines the method. See

`PyType_GetModuleByDef()` for cases when `PyCMethod` cannot be used.

*New in version 3.9.*

`void *PyType_GetModuleState(PyTypeObject *type)`

*Part of the [Stable ABI](#) since version 3.10.*

Return the state of the module object associated with the given type. This is a shortcut for calling

`PyModule_GetState()` on the result of

`PyType_GetModule()`.

If no module is associated with the given type, sets

`TypeError` and returns `NULL`.

If the *type* has an associated module but its state is `NULL`, returns `NULL` without setting an exception.

*New in version 3.9.*

`PyObject *PyType_GetModuleByDef(PyTypeObject *type, struct PyModuleDef *def)`

Find the first superclass whose module was created from the given `PyModuleDef` *def*, and return that module.

If no module is found, raises a `TypeError` and returns

NULL.

This function is intended to be used together with `PyModule_GetState()` to get module state from slot methods (such as `tp_init` or `nb_add`) and other places where a method's defining class cannot be passed using the `PyCMethod` calling convention.

*New in version 3.11.*

```
int PyUnstable_Type_AssignVersionTag(PyTypeObject *type)
```

*This is **Unstable API**. It may change without warning in minor releases.*

Attempt to assign a version tag to the given type.

Returns 1 if the type already had a valid version tag or a new one was assigned, or 0 if a new tag could not be assigned.

*New in version 3.12.*

## Creating Heap-Allocated Types

The following functions and structs are used to create **heap types**.

```
PyObject *PyType_FromMetaclass(PyTypeObject *metaclass,  
PyObject *module, PyType_Spec *spec, PyObject *bases)
```

*Part of the **Stable ABI** since version 3.12.*

Create and return a **heap type** from the *spec* (see `Py_TPFLAGS_HEAPTYPE`).

The metaclass *metaclass* is used to construct the resulting type object. When *metaclass* is NULL, the metaclass is derived from *bases* (or *Py\_tp\_base[s]* slots if *bases* is NULL, see below).

Metaclasses that override `tp_new` are not supported, except if `tp_new` is NULL. (For backwards compatibility, other `PyType_From*` functions allow such metaclasses. They

ignore `tp_new`, which may result in incomplete initialization. This is deprecated and in Python 3.14+ such metaclasses will not be supported.)

The *bases* argument can be used to specify base classes; it can either be only one class or a tuple of classes. If *bases* is `NULL`, the `Py_tp_bases` slot is used instead. If that also is `NULL`, the `Py_tp_base` slot is used instead. If that also is `NULL`, the new type derives from `object`.

The *module* argument can be used to record the module in which the new class is defined. It must be a module object or `NULL`. If not `NULL`, the module is associated with the new type and can later be retrieved with `PyType_GetModule()`. The associated module is not inherited by subclasses; it must be specified for each class individually.

This function calls `PyType_Ready()` on the new type.

Note that this function does *not* fully match the behavior of calling `type()` or using the `class` statement. With user-provided base types or metaclasses, prefer calling `type` (or the metaclass) over `PyType_From*` functions. Specifically:

- `__new__()` is not called on the new class (and it must be set to `type.__new__`).
- `__init__()` is not called on the new class.
- `__init_subclass__()` is not called on any bases.
- `__set_name__()` is not called on new descriptors.

*New in version 3.12.*

`PyObject *PyType_FromModuleAndSpec(PyObject *module, PyType_Spec *spec, PyObject *bases)`

*Return value:* New reference. Part of the *Stable ABI* since version 3.10.

Equivalent to `PyType_FromMetaclass(NULL, module, spec, bases)`.

*New in version 3.9.*

*Changed in version 3.10:* The function now accepts a single class as the *bases* argument and `NULL` as the `tp_doc` slot.

*Changed in version 3.12:* The function now finds and uses a metaclass corresponding to the provided base classes. Previously, only `type` instances were returned.

The `tp_new` of the metaclass is *ignored*. which may result in incomplete initialization. Creating classes whose metaclass overrides `tp_new` is deprecated and in Python 3.14+ it will be no longer allowed.

`PyObject *``PyType_FromSpecWithBases(PyType_Spec *spec,`  
`PyObject *bases)`

*Return value:* New reference. Part of the [Stable ABI](#) since version 3.3.

Equivalent to `PyType_FromMetaclass(NULL, NULL, spec, bases)`.

*New in version 3.3.*

*Changed in version 3.12:* The function now finds and uses a metaclass corresponding to the provided base classes. Previously, only `type` instances were returned.

The `tp_new` of the metaclass is *ignored*. which may result in incomplete initialization. Creating classes whose metaclass overrides `tp_new` is deprecated and in Python 3.14+ it will be no longer allowed.

`PyObject *``PyType_FromSpec(PyType_Spec *spec)`

*Return value:* New reference. Part of the [Stable ABI](#).

Equivalent to `PyType_FromMetaclass(NULL, NULL, spec, NULL)`.

*Changed in version 3.12:* The function now finds and uses a metaclass corresponding to the base classes provided in `Py_tp_base[s]` slots. Previously, only `type` instances were returned.

The `tp_new` of the metaclass is *ignored*. which may result in incomplete initialization. Creating classes whose metaclass overrides `tp_new` is deprecated and in Python 3.14+ it will be no longer allowed.

type PyType\_Spec

Part of the *Stable ABI* (including all members).

Structure defining a type's behavior.

const char \*name

Name of the type, used to set

`PyTypeObject.tp_name`.

int basicsize

If positive, specifies the size of the instance in bytes. It is used to set `PyTypeObject.tp_basicsize`.

If zero, specifies that `tp_basicsize` should be inherited.

If negative, the absolute value specifies how much space instances of the class need *in addition* to the superclass. Use `PyObject_GetTypeData()` to get a pointer to subclass-specific memory reserved this way.

*Changed in version 3.12:* Previously, this field could not be negative.

int itemsize

Size of one element of a variable-size type, in bytes.

Used to set `PyTypeObject.tp_itemsize`. See `tp_itemsize` documentation for caveats.

If zero, `tp_itemsize` is inherited. Extending arbitrary variable-sized classes is dangerous, since some types use a fixed offset for variable-sized memory, which can then overlap fixed-sized memory used by a subclass. To help prevent mistakes, inheriting `itemsize` is only possible in the following situations:

- The base is not variable-sized (its `tp_itemsize`).
- The requested `PyType_Spec.basicsize` is positive, suggesting that the memory layout of the base class is known.
- The requested `PyType_Spec.basicsize` is zero, suggesting that the subclass does not access the instance's memory directly.
- With the `Py_TPFLAGS_ITEMS_AT_END` flag.

unsigned int flags

Type flags, used to set `PyObject.tp_flags`.

If the `Py_TPFLAGS_HEAPTYPE` flag is not set, `PyType_FromSpecWithBases()` sets it automatically.

`PyType_Slot` \*slots

Array of `PyType_Slot` structures. Terminated by the special slot value `{0, NULL}`.

Each slot ID should be specified at most once.

type `PyType_Slot`

*Part of the [Stable ABI](#) (including all members).*

Structure defining optional functionality of a type, containing a slot ID and a value pointer.

int slot

A slot ID.

Slot IDs are named like the field names of the structures `PyObject`, `PyNumberMethods`, `PySequenceMethods`, `PyMappingMethods` and `PyAsyncMethods` with an added `Py_` prefix. For example, use:

- `Py_tp_dealloc` to set `PyTypeObject.tp_dealloc`
- `Py_nb_add` to set `PyNumberMethods.nb_add`
- `Py_sq_length` to set `PySequenceMethods.sq_length`

The following fields cannot be set at all using `PyType_Spec` and `PyType_Slot`:

- `tp_dict`
- `tp_mro`
- `tp_cache`
- `tp_subclasses`
- `tp_weaklist`
- `tp_vectorcall`
- `tp_weaklistoffset` (use `Py_TPFLAGS_MANAGED_WEAKREF` instead)
- `tp_dictoffset` (use `Py_TPFLAGS_MANAGED_DICT` instead)
- `tp_vectorcall_offset` (see `PyMemberDef`)

Setting `Py_tp_bases` or `Py_tp_base` may be problematic on some platforms. To avoid issues, use the *bases* argument of `PyType_FromSpecWithBases()` instead.

*Changed in version 3.9:* Slots in `PyBufferProcs` may be set in the unlimited API.

*Changed in version 3.11:* `bf_getbuffer` and `bf_releasebuffer` are now available under the limited API.

`void *pfunc`

The desired value of the slot. In most cases, this is a pointer to a function.

Slots other than `Py_tp_doc` may not be `NULL`.

# The None Object

Note that the `PyObject` for `None` is not directly exposed in the Python/C API. Since `None` is a singleton, testing for object identity (using `==` in C) is sufficient. There is no `PyNone_Check()` function for the same reason.

`PyObject *``Py_None`

The Python `None` object, denoting lack of value. This object has no methods and is `immortal` [<https://peps.python.org/pep-0683/>].

*Changed in version 3.12:* `Py_None` is immortal.

`Py_RETURN_NONE`

Return `Py_None` from a function.

# Integer Objects

All integers are implemented as “long” integer objects of arbitrary size.

On error, most `PyLong_As*` APIs return `(return type)-1` which cannot be distinguished from a number. Use `PyErr_Occurred()` to disambiguate.

type `PyLongObject`

*Part of the [Limited API](#) (as an opaque struct).*

This subtype of `PyObject` represents a Python integer object.

`PyTypeObject` `PyLong_Type`

*Part of the [Stable ABI](#).*

This instance of `PyTypeObject` represents the Python integer type. This is the same object as `int` in the Python layer.

int `PyLong_Check(PyObject *p)`

Return true if its argument is a `PyLongObject` or a subtype of `PyLongObject`. This function always succeeds.

int `PyLong_CheckExact(PyObject *p)`

Return true if its argument is a `PyLongObject`, but not a subtype of `PyLongObject`. This function always succeeds.

`PyObject *``PyLong_FromLong(long v)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new `PyLongObject` object from `v`, or `NULL` on failure.

The current implementation keeps an array of integer objects

for all integers between  $-5$  and  $2^{56}$ . When you create an int in that range you actually just get back a reference to the existing object.

**PyObject \***PyLong\_FromUnsignedLong(unsigned long v)

*Return value:* New reference. Part of the [Stable ABI](#).

Return a new **PyLongObject** object from a C unsigned long, or NULL on failure.

**PyObject \***PyLong\_FromSize\_t(Py\_ssize\_t v)

*Return value:* New reference. Part of the [Stable ABI](#).

Return a new **PyLongObject** object from a C **Py\_ssize\_t**, or NULL on failure.

**PyObject \***PyLong\_FromSize\_t(size\_t v)

*Return value:* New reference. Part of the [Stable ABI](#).

Return a new **PyLongObject** object from a C **size\_t**, or NULL on failure.

**PyObject \***PyLong\_FromLongLong(long long v)

*Return value:* New reference. Part of the [Stable ABI](#).

Return a new **PyLongObject** object from a C long long, or NULL on failure.

**PyObject \***PyLong\_FromUnsignedLongLong(unsigned long long v)

*Return value:* New reference. Part of the [Stable ABI](#).

Return a new **PyLongObject** object from a C unsigned long long, or NULL on failure.

**PyObject \***PyLong\_FromDouble(double v)

*Return value:* New reference. Part of the [Stable ABI](#).

Return a new **PyLongObject** object from the integer part of v, or NULL on failure.

**PyObject \***PyLong\_FromString(const char \*str, char \*\*pend, int base)

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new [PyLongObject](#) based on the string value in *str*, which is interpreted according to the radix in *base*, or NULL on failure. If *pend* is non-NULL, *\*pend* will point to the end of *str* on success or to the first character that could not be processed on error. If *base* is 0, *str* is interpreted using the [Integer literals](#) definition; in this case, leading zeros in a non-zero decimal number raises a [ValueError](#). If *base* is not 0, it must be between 2 and 36, inclusive. Leading and trailing whitespace and single underscores after a base specifier and between digits are ignored. If there are no digits or *str* is not NULL-terminated following the digits and trailing whitespace, [ValueError](#) will be raised.

### See also

Python methods [int.to\\_bytes\(\)](#) and [int.from\\_bytes\(\)](#) to convert a [PyLongObject](#) to/from an array of bytes in base 256. You can call those from C using [PyObject\\_CallMethod\(\)](#).

[PyObject](#) \*PyLong\_FromUnicodeObject([PyObject](#) \*u, int base)

*Return value: New reference.*

Convert a sequence of Unicode digits in the string *u* to a Python integer value.

*New in version 3.3.*

[PyObject](#) \*PyLong\_FromVoidPtr(void \*p)

*Return value: New reference. Part of the [Stable ABI](#).*

Create a Python integer from the pointer *p*. The pointer value can be retrieved from the resulting value using [PyLong\\_AsVoidPtr\(\)](#).

long PyLong\_AsLong([PyObject](#) \*obj)

*Part of the [Stable ABI](#).*

Return a C long representation of *obj*. If *obj* is not an instance

of `PyLongObject`, first call its `__index__()` method (if present) to convert it to a `PyLongObject`.

Raise `OverflowError` if the value of `obj` is out of range for a long.

Returns `-1` on error. Use `PyErr_Occurred()` to disambiguate.

*Changed in version 3.8:* Use `__index__()` if available.

*Changed in version 3.10:* This function will no longer use `__int__()`.

`long PyLong_AsLongAndOverflow(PyObject *obj, int *overflow)`

*Part of the [Stable ABI](#).*

Return a C long representation of `obj`. If `obj` is not an instance of `PyLongObject`, first call its `__index__()` method (if present) to convert it to a `PyLongObject`.

If the value of `obj` is greater than `LONG_MAX` or less than `LONG_MIN`, set `*overflow` to `1` or `-1`, respectively, and return `-1`; otherwise, set `*overflow` to `0`. If any other exception occurs set `*overflow` to `0` and return `-1` as usual.

Returns `-1` on error. Use `PyErr_Occurred()` to disambiguate.

*Changed in version 3.8:* Use `__index__()` if available.

*Changed in version 3.10:* This function will no longer use `__int__()`.

`long long PyLong_AsLongLong(PyObject *obj)`

*Part of the [Stable ABI](#).*

Return a C long long representation of `obj`. If `obj` is not an instance of `PyLongObject`, first call its `__index__()` method (if present) to convert it to a `PyLongObject`.

Raise `OverflowError` if the value of `obj` is out of range for

a long long.

Returns `-1` on error. Use `PyErr_Occurred()` to disambiguate.

*Changed in version 3.8:* Use `__index__()` if available.

*Changed in version 3.10:* This function will no longer use `__int__()`.

`long long PyLong_AsLongLongAndOverflow(PyObject *obj, int *overflow)`

*Part of the [Stable ABI](#).*

Return a C long long representation of *obj*. If *obj* is not an instance of `PyLongObject`, first call its `__index__()` method (if present) to convert it to a `PyLongObject`.

If the value of *obj* is greater than `LLONG_MAX` or less than `LLONG_MIN`, set *\*overflow* to `1` or `-1`, respectively, and return `-1`; otherwise, set *\*overflow* to `0`. If any other exception occurs set *\*overflow* to `0` and return `-1` as usual.

Returns `-1` on error. Use `PyErr_Occurred()` to disambiguate.

*New in version 3.2.*

*Changed in version 3.8:* Use `__index__()` if available.

*Changed in version 3.10:* This function will no longer use `__int__()`.

`Py_ssize_t PyLong_AsSsize_t(PyObject *pylong)`

*Part of the [Stable ABI](#).*

Return a C `Py_ssize_t` representation of *pylong*. *pylong* must be an instance of `PyLongObject`.

Raise `OverflowError` if the value of *pylong* is out of range for a `Py_ssize_t`.

Returns `-1` on error. Use `PyErr_Occurred()` to disambiguate.

`unsigned long PyLong_AsUnsignedLong(PyObject *pylong)`

*Part of the [Stable ABI](#).*

Return a C unsigned long representation of *pylong*. *pylong* must be an instance of `PyLongObject`.

Raise `OverflowError` if the value of *pylong* is out of range for a unsigned long.

Returns `(unsigned long)-1` on error. Use `PyErr_Occurred()` to disambiguate.

`size_t PyLong_AsSize_t(PyObject *pylong)`

*Part of the [Stable ABI](#).*

Return a C `size_t` representation of *pylong*. *pylong* must be an instance of `PyLongObject`.

Raise `OverflowError` if the value of *pylong* is out of range for a `size_t`.

Returns `(size_t)-1` on error. Use `PyErr_Occurred()` to disambiguate.

`unsigned long long PyLong_AsUnsignedLongLong(PyObject *pylong)`

*Part of the [Stable ABI](#).*

Return a C unsigned long long representation of *pylong*. *pylong* must be an instance of `PyLongObject`.

Raise `OverflowError` if the value of *pylong* is out of range for an unsigned long long.

Returns `(unsigned long long)-1` on error. Use `PyErr_Occurred()` to disambiguate.

*Changed in version 3.1:* A negative *pylong* now raises `OverflowError`, not `TypeError`.

unsigned long PyLong\_AsUnsignedLongMask([PyObject](#) \*obj)

*Part of the [Stable ABI](#).*

Return a C unsigned long representation of *obj*. If *obj* is not an instance of [PyLongObject](#), first call its [\\_\\_index\\_\\_\(\)](#) method (if present) to convert it to a [PyLongObject](#).

If the value of *obj* is out of range for an unsigned long, return the reduction of that value modulo `ULONG_MAX + 1`.

Returns (unsigned long)-1 on error. Use [PyErr\\_Occurred\(\)](#) to disambiguate.

*Changed in version 3.8:* Use [\\_\\_index\\_\\_\(\)](#) if available.

*Changed in version 3.10:* This function will no longer use [\\_\\_int\\_\\_\(\)](#).

unsigned long long PyLong\_AsUnsignedLongLongMask([PyObject](#) \*obj)

*Part of the [Stable ABI](#).*

Return a C unsigned long long representation of *obj*. If *obj* is not an instance of [PyLongObject](#), first call its [\\_\\_index\\_\\_\(\)](#) method (if present) to convert it to a [PyLongObject](#).

If the value of *obj* is out of range for an unsigned long long, return the reduction of that value modulo `ULLONG_MAX + 1`.

Returns (unsigned long long)-1 on error. Use [PyErr\\_Occurred\(\)](#) to disambiguate.

*Changed in version 3.8:* Use [\\_\\_index\\_\\_\(\)](#) if available.

*Changed in version 3.10:* This function will no longer use [\\_\\_int\\_\\_\(\)](#).

double PyLong\_AsDouble([PyObject](#) \*pylong)

*Part of the [Stable ABI](#).*

Return a C double representation of *pylong*. *pylong* must be an

instance of `PyLongObject`.

Raise `OverflowError` if the value of `pylong` is out of range for a double.

Returns `-1.0` on error. Use `PyErr_Occurred()` to disambiguate.

`void *PyLong_AsVoidPtr(PyObject *pylong)`

*Part of the `Stable ABI`.*

Convert a Python integer `pylong` to a C void pointer. If `pylong` cannot be converted, an `OverflowError` will be raised. This is only assured to produce a usable void pointer for values created with `PyLong_FromVoidPtr()`.

Returns `NULL` on error. Use `PyErr_Occurred()` to disambiguate.

`int PyUnstable_Long_IsCompact(const PyLongObject *op)`

*This is `Unstable API`. It may change without warning in minor releases.*

Return 1 if `op` is compact, 0 otherwise.

This function makes it possible for performance-critical code to implement a “fast path” for small integers. For compact values use `PyUnstable_Long_CompactValue()`; for others fall back to a `PyLong_As*` function or `calling int.to_bytes()`.

The speedup is expected to be negligible for most users.

Exactly what values are considered compact is an implementation detail and is subject to change.

`Py_ssize_t PyUnstable_Long_CompactValue(const PyLongObject *op)`

*This is **Unstable API**. It may change without warning in minor releases.*

If *op* is compact, as determined by **PyUnstable\_Long\_IsCompact()**, return its value.

Otherwise, the return value is undefined.

# Boolean Objects

Booleans in Python are implemented as a subclass of integers. There are only two booleans, `Py_False` and `Py_True`. As such, the normal creation and deletion functions don't apply to booleans. The following macros are available, however.

`PyTypeObject` `PyBool_Type`

*Part of the [Stable ABI](#).*

This instance of `PyTypeObject` represents the Python boolean type; it is the same object as `bool` in the Python layer.

`int` `PyBool_Check(PyObject *o)`

Return true if `o` is of type `PyBool_Type`. This function always succeeds.

`PyObject` `*Py_False`

The Python `False` object. This object has no methods and is [immortal](https://peps.python.org/pep-0683/) [https://peps.python.org/pep-0683/].

*Changed in version 3.12:* `Py_False` is immortal.

`PyObject` `*Py_True`

The Python `True` object. This object has no methods and is [immortal](https://peps.python.org/pep-0683/) [https://peps.python.org/pep-0683/].

*Changed in version 3.12:* `Py_True` is immortal.

`Py_RETURN_FALSE`

Return `Py_False` from a function.

`Py_RETURN_TRUE`

Return `Py_True` from a function.

`PyObject *`PyBool\_FromLong(long v)

*Return value: New reference. Part of the [Stable ABI](#).*

Return `Py_True` or `Py_False`, depending on the truth value of v.

# Floating Point Objects

type PyFloatObject

This subtype of **PyObject** represents a Python floating point object.

**PyTypeObject** PyFloat\_Type

*Part of the **Stable ABI**.*

This instance of **PyTypeObject** represents the Python floating point type. This is the same object as **float** in the Python layer.

int PyFloat\_Check(**PyObject** \*p)

Return true if its argument is a **PyFloatObject** or a subtype of **PyFloatObject**. This function always succeeds.

int PyFloat\_CheckExact(**PyObject** \*p)

Return true if its argument is a **PyFloatObject**, but not a subtype of **PyFloatObject**. This function always succeeds.

**PyObject** \*PyFloat\_FromString(**PyObject** \*str)

*Return value: New reference. Part of the **Stable ABI**.*

Create a **PyFloatObject** object based on the string value in *str*, or **NULL** on failure.

**PyObject** \*PyFloat\_FromDouble(double v)

*Return value: New reference. Part of the **Stable ABI**.*

Create a **PyFloatObject** object from *v*, or **NULL** on failure.

double PyFloat\_AsDouble(**PyObject** \*pyfloat)

*Part of the **Stable ABI**.*

Return a C double representation of the contents of *pyfloat*. If

`pyfloat` is not a Python floating point object but has a `__float__()` method, this method will first be called to convert `pyfloat` into a float. If `__float__()` is not defined then it falls back to `__index__()`. This method returns `-1.0` upon failure, so one should call `PyErr_Occurred()` to check for errors.

*Changed in version 3.8:* Use `__index__()` if available.

`double PyFloat_AS_DOUBLE(PyObject *pyfloat)`

Return a C double representation of the contents of `pyfloat`, but without error checking.

`PyObject *PyFloat_GetInfo(void)`

*Return value:* New reference. Part of the [Stable ABI](#).

Return a structseq instance which contains information about the precision, minimum and maximum values of a float. It's a thin wrapper around the header file `float.h`.

`double PyFloat_GetMax()`

*Part of the [Stable ABI](#).*

Return the maximum representable finite float `DBL_MAX` as C double.

`double PyFloat_GetMin()`

*Part of the [Stable ABI](#).*

Return the minimum normalized positive float `DBL_MIN` as C double.

## Pack and Unpack functions

The pack and unpack functions provide an efficient platform-independent way to store floating-point values as byte strings. The Pack routines produce a bytes string from a C double, and the Unpack routines produce a C double from such a bytes string. The suffix (2, 4 or 8) specifies the number of bytes in the bytes string.

On platforms that appear to use IEEE 754 formats these functions work by copying bits. On other platforms, the 2-byte format is identical to the IEEE 754 binary16 half-precision format, the 4-byte format (32-bit) is identical to the IEEE 754 binary32 single precision format, and the 8-byte format to the IEEE 754 binary64 double precision format, although the packing of INFs and NaNs (if such things exist on the platform) isn't handled correctly, and attempting to unpack a bytes string containing an IEEE INF or NaN will raise an exception.

On non-IEEE platforms with more precision, or larger dynamic range, than IEEE 754 supports, not all values can be packed; on non-IEEE platforms with less precision, or smaller dynamic range, not all values can be unpacked. What happens in such cases is partly accidental (alas).

*New in version 3.11.*

## Pack functions

The pack routines write 2, 4 or 8 bytes, starting at *p*. *le* is an int argument, non-zero if you want the bytes string in little-endian format (exponent last, at *p*+1, *p*+3, or *p*+6 *p*+7), zero if you want big-endian format (exponent first, at *p*). The **PY\_BIG\_ENDIAN** constant can be used to use the native endian: it is equal to 1 on big endian processor, or 0 on little endian processor.

Return value: 0 if all is OK, -1 if error (and an exception is set, most likely **OverflowError**).

There are two problems on non-IEEE platforms:

- What this does is undefined if *x* is a NaN or infinity.
- `-0.0` and `+0.0` produce the same bytes string.

`int PyFloat_Pack2(double x, unsigned char *p, int le)`

Pack a C double as the IEEE 754 binary16 half-precision format.

`int PyFloat_Pack4(double x, unsigned char *p, int le)`

Pack a C double as the IEEE 754 binary32 single precision format.

`int PyFloat_Pack8(double x, unsigned char *p, int le)`

Pack a C double as the IEEE 754 binary64 double precision format.

## Unpack functions

The unpack routines read 2, 4 or 8 bytes, starting at *p*. *le* is an int argument, non-zero if the bytes string is in little-endian format (exponent last, at *p*+1, *p*+3 or *p*+6 and *p*+7), zero if big-endian (exponent first, at *p*). The **PY\_BIG\_ENDIAN** constant can be used to use the native endian: it is equal to 1 on big endian processor, or 0 on little endian processor.

Return value: The unpacked double. On error, this is `-1.0` and **PyErr\_Occurred()** is true (and an exception is set, most likely **OverflowError**).

Note that on a non-IEEE platform this will refuse to unpack a bytes string that represents a NaN or infinity.

`double PyFloat_Unpack2(const unsigned char *p, int le)`

Unpack the IEEE 754 binary16 half-precision format as a C double.

`double PyFloat_Unpack4(const unsigned char *p, int le)`

Unpack the IEEE 754 binary32 single precision format as a C double.

`double PyFloat_Unpack8(const unsigned char *p, int le)`

Unpack the IEEE 754 binary64 double precision format as a C double.

# Complex Number Objects

Python's complex number objects are implemented as two distinct types when viewed from the C API: one is the Python object exposed to Python programs, and the other is a C structure which represents the actual complex number value. The API provides functions for working with both.

## Complex Numbers as C Structures

Note that the functions which accept these structures as parameters and return them as results do so *by value* rather than dereferencing them through pointers. This is consistent throughout the API.

type `Py_complex`

The C structure which corresponds to the value portion of a Python complex number object. Most of the functions for dealing with complex number objects use structures of this type as input or output values, as appropriate. It is defined as:

```
typedef struct {  
    double real;  
    double imag;  
} Py_complex;
```

`Py_complex_Py_c_sum(Py_complex left, Py_complex right)`

Return the sum of two complex numbers, using the C `Py_complex` representation.

`Py_complex_Py_c_diff(Py_complex left, Py_complex right)`

Return the difference between two complex numbers, using the C `Py_complex` representation.

`Py_complex_Py_c_neg(Py_complex num)`

Return the negation of the complex number *num*, using the C **Py\_complex** representation.

**Py\_complex** \_Py\_c\_prod(**Py\_complex** left, **Py\_complex** right)  
Return the product of two complex numbers, using the C **Py\_complex** representation.

**Py\_complex** \_Py\_c\_quot(**Py\_complex** dividend, **Py\_complex** divisor)  
Return the quotient of two complex numbers, using the C **Py\_complex** representation.

If *divisor* is null, this method returns zero and sets **errno** to **EDOM**.

**Py\_complex** \_Py\_c\_pow(**Py\_complex** num, **Py\_complex** exp)  
Return the exponentiation of *num* by *exp*, using the C **Py\_complex** representation.

If *num* is null and *exp* is not a positive real number, this method returns zero and sets **errno** to **EDOM**.

## Complex Numbers as Python Objects

type PyComplexObject

This subtype of **PyObject** represents a Python complex number object.

**PyTypeObject** PyComplex\_Type

*Part of the [Stable ABI](#).*

This instance of **PyTypeObject** represents the Python complex number type. It is the same object as **complex** in the Python layer.

int PyComplex\_Check(**PyObject** \*p)

Return true if its argument is a **PyComplexObject** or a subtype of **PyComplexObject**. This function always succeeds.

`int PyComplex_CheckExact(PyObject *p)`

Return true if its argument is a `PyComplexObject`, but not a subtype of `PyComplexObject`. This function always succeeds.

`PyObject *PyComplex_FromCComplex(Py_complex v)`

*Return value:* New reference.

Create a new Python complex number object from a C `Py_complex` value.

`PyObject *PyComplex_FromDoubles(double real, double imag)`

*Return value:* New reference. Part of the *Stable ABI*.

Return a new `PyComplexObject` object from *real* and *imag*.

`double PyComplex_RealAsDouble(PyObject *op)`

*Part of the Stable ABI.*

Return the real part of *op* as a C double.

`double PyComplex_ImagAsDouble(PyObject *op)`

*Part of the Stable ABI.*

Return the imaginary part of *op* as a C double.

`Py_complex PyComplex_AsCComplex(PyObject *op)`

Return the `Py_complex` value of the complex number *op*.

If *op* is not a Python complex number object but has a `__complex__()` method, this method will first be called to convert *op* to a Python complex number object. If `__complex__()` is not defined then it falls back to `__float__()`. If `__float__()` is not defined then it falls back to `__index__()`. Upon failure, this method returns `-1.0` as a real value.

*Changed in version 3.8:* Use `__index__()` if available.

# Bytes Objects

These functions raise **TypeError** when expecting a bytes parameter and called with a non-bytes parameter.

type PyBytesObject

This subtype of **PyObject** represents a Python bytes object.

**PyTypeObject** PyBytes\_Type

*Part of the **Stable ABI**.*

This instance of **PyTypeObject** represents the Python bytes type; it is the same object as **bytes** in the Python layer.

int PyBytes\_Check(**PyObject** \*o)

Return true if the object *o* is a bytes object or an instance of a subtype of the bytes type. This function always succeeds.

int PyBytes\_CheckExact(**PyObject** \*o)

Return true if the object *o* is a bytes object, but not an instance of a subtype of the bytes type. This function always succeeds.

**PyObject** \*PyBytes\_FromString(const char \*v)

*Return value: New reference. Part of the **Stable ABI**.*

Return a new bytes object with a copy of the string *v* as value on success, and **NULL** on failure. The parameter *v* must not be **NULL**; it will not be checked.

**PyObject** \*PyBytes\_FromStringAndSize(const char \*v, **Py\_ssize\_t** len)

*Return value: New reference. Part of the **Stable ABI**.*

Return a new bytes object with a copy of the string *v* as value and length *len* on success, and **NULL** on failure. If *v* is **NULL**, the contents of the bytes object are uninitialized.

**PyObject** \*PyBytes\_FromFormat(const char \*format, ...)

*Return value:* New reference. Part of the [Stable ABI](#).

Take a C **printf()**-style *format* string and a variable number of arguments, calculate the size of the resulting Python bytes object and return a bytes object with the values formatted into it. The variable arguments must be C types and must correspond exactly to the format characters in the *format* string. The following format characters are allowed:

### **Format Characters**

---

~~The~~ literal % character.

---

~~A~~ single byte, represented as a C int.

---

~~E~~quivalent to `printf("%d").` [1](#)

---

~~E~~quivalent to `printf("%u").` [1](#)

---

~~E~~quivalent to `printf("%ld").` [1](#)

---

~~E~~quivalent to `printf("%lu").` [1](#)

---

~~E~~quivalent to `printf("%zd").` [1](#)

---

~~E~~quivalent to `printf("%zu").` [1](#)

---

~~E~~quivalent to `printf("%i").` [1](#)

---

~~E~~quivalent to `printf("%x").` [1](#)

---

~~A~~ null-terminated C character array.

---

~~The~~ void representation of a C pointer. Mostly equivalent to `printf("%p")` except that it is guaranteed to start with the literal `0x` regardless of what the platform's `printf` yields.

---

An unrecognized format character causes all the rest of the format string to be copied as-is to the result object, and any extra arguments discarded.

1([1](#),[2](#),[3](#),[4](#),[5](#),[6](#),[7](#),[8](#))

For integer specifiers (d, u, ld, lu, zd, zu, i, x): the 0-conversion flag has effect even when a precision is given.

**PyObject** \*PyBytes\_FromFormatV(const char \*format, va\_list vargs)

*Return value:* New reference. Part of the [Stable ABI](#).

Identical to **PyBytes\_FromFormat()** except that it takes exactly two arguments.

`PyObject *PyBytes_FromObject(PyObject *o)`

*Return value:* New reference. Part of the [Stable ABI](#).

Return the bytes representation of object *o* that implements the buffer protocol.

`Py_ssize_t PyBytes_Size(PyObject *o)`

*Part of the [Stable ABI](#).*

Return the length of the bytes in bytes object *o*.

`Py_ssize_t PyBytes_GET_SIZE(PyObject *o)`

Similar to [PyBytes\\_Size\(\)](#), but without error checking.

`char *PyBytes_AsString(PyObject *o)`

*Part of the [Stable ABI](#).*

Return a pointer to the contents of *o*. The pointer refers to the internal buffer of *o*, which consists of `len(o) + 1` bytes.

The last byte in the buffer is always null, regardless of whether there are any other null bytes. The data must not be modified in any way, unless the object was just created using `PyBytes_FromStringAndSize(NULL, size)`. It must not be deallocated. If *o* is not a bytes object at all,

[PyBytes\\_AsString\(\)](#) returns `NULL` and raises [TypeError](#).

`char *PyBytes_AS_STRING(PyObject *string)`

Similar to [PyBytes\\_AsString\(\)](#), but without error checking.

`int PyBytes_AsStringAndSize(PyObject *obj, char **buffer, Py_ssize_t *length)`

*Part of the [Stable ABI](#).*

Return the null-terminated contents of the object *obj* through the output variables *buffer* and *length*.

If *length* is `NULL`, the bytes object may not contain embedded null bytes; if it does, the function returns `-1` and a [ValueError](#) is raised.

The buffer refers to an internal buffer of *obj*, which includes an additional null byte at the end (not counted in *length*). The data must not be modified in any way, unless the object was just created using `PyBytes_FromStringAndSize(NULL, size)`. It must not be deallocated. If *obj* is not a bytes object at all, `PyBytes_AsStringAndSize()` returns `-1` and raises `TypeError`.

*Changed in version 3.5:* Previously, `TypeError` was raised when embedded null bytes were encountered in the bytes object.

`void PyBytes_Concat(PyObject **bytes, PyObject *newpart)`

*Part of the [Stable ABI](#).*

Create a new bytes object in *\*bytes* containing the contents of *newpart* appended to *bytes*; the caller will own the new reference. The reference to the old value of *bytes* will be stolen. If the new object cannot be created, the old reference to *bytes* will still be discarded and the value of *\*bytes* will be set to `NULL`; the appropriate exception will be set.

`void PyBytes_ConcatAndDel(PyObject **bytes, PyObject *newpart)`

*Part of the [Stable ABI](#).*

Create a new bytes object in *\*bytes* containing the contents of *newpart* appended to *bytes*. This version releases the [strong reference](#) to *newpart* (i.e. decrements its reference count).

`int _PyBytes_Resize(PyObject **bytes, Py_ssize_t newsize)`

A way to resize a bytes object even though it is “immutable”. Only use this to build up a brand new bytes object; don’t use this if the bytes may already be known in other parts of the code. It is an error to call this function if the refcount on the input bytes object is not one. Pass the address of an existing bytes object as an lvalue (it may be written into), and the new size desired. On success, *\*bytes* holds the resized bytes object and `0` is returned; the address in *\*bytes* may differ from its input value. If the reallocation fails, the original bytes object at *\*bytes* is deallocated, *\*bytes* is set to `NULL`,

**MemoryError** is set, and `-1` is returned.

# Byte Array Objects

type PyByteArrayObject

This subtype of [PyObject](#) represents a Python bytearray object.

[PyTypeObject](#) PyByteArray\_Type

*Part of the [Stable ABI](#).*

This instance of [PyTypeObject](#) represents the Python bytearray type; it is the same object as [bytearray](#) in the Python layer.

## Type check macros

int PyByteArray\_Check([PyObject](#) \*o)

Return true if the object *o* is a bytearray object or an instance of a subtype of the bytearray type. This function always succeeds.

int PyByteArray\_CheckExact([PyObject](#) \*o)

Return true if the object *o* is a bytearray object, but not an instance of a subtype of the bytearray type. This function always succeeds.

## Direct API functions

[PyObject](#) \*PyByteArray\_FromObject([PyObject](#) \*o)

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new bytearray object from any object, *o*, that implements the [buffer protocol](#).

[PyObject](#) \*PyByteArray\_FromStringAndSize(const char \*string,

`Py_ssize_t len)`

*Return value: New reference. Part of the [Stable ABI](#).*

Create a new bytearray object from *string* and its length, *len*.  
On failure, `NULL` is returned.

`PyObject *PyByteArray_Concat(PyObject *a, PyObject *b)`

*Return value: New reference. Part of the [Stable ABI](#).*

Concat bytearrays *a* and *b* and return a new bytearray with the result.

`Py_ssize_t PyByteArray_Size(PyObject *bytearray)`

*Part of the [Stable ABI](#).*

Return the size of *bytearray* after checking for a `NULL` pointer.

`char *PyByteArray_AsString(PyObject *bytearray)`

*Part of the [Stable ABI](#).*

Return the contents of *bytearray* as a char array after checking for a `NULL` pointer. The returned array always has an extra null byte appended.

`int PyByteArray_Resize(PyObject *bytearray, Py_ssize_t len)`

*Part of the [Stable ABI](#).*

Resize the internal buffer of *bytearray* to *len*.

## Macros

These macros trade safety for speed and they don't check pointers.

`char *PyByteArray_AS_STRING(PyObject *bytearray)`

Similar to `PyByteArray_AsString()`, but without error checking.

`Py_ssize_t PyByteArray_GET_SIZE(PyObject *bytearray)`

Similar to `PyByteArray_Size()`, but without error checking.

# Unicode Objects and Codecs

## Unicode Objects

Since the implementation of [PEP 393](https://peps.python.org/pep-0393/) [https://peps.python.org/pep-0393/] in Python 3.3, Unicode objects internally use a variety of representations, in order to allow handling the complete range of Unicode characters while staying memory efficient. There are special cases for strings where all code points are below 128, 256, or 65536; otherwise, code points must be below 1114112 (which is the full Unicode range).

UTF-8 representation is created on demand and cached in the Unicode object.

### Note

The [Py\\_UNICODE](https://peps.python.org/pep-0623/) representation has been removed since Python 3.12 with deprecated APIs. See [PEP 623](https://peps.python.org/pep-0623/) [https://peps.python.org/pep-0623/] for more information.

## Unicode Type

These are the basic Unicode object types used for the Unicode implementation in Python:

type `Py_UCS4`

type `Py_UCS2`

type `Py_UCS1`

*Part of the [Stable ABI](#).*

These types are typedefs for unsigned integer types wide enough to contain characters of 32 bits, 16 bits and 8 bits, respectively. When dealing with single Unicode characters, use [Py\\_UCS4](#).

*New in version 3.3.*

type Py\_UNICODE

This is a typedef of `wchar_t`, which is a 16-bit type or 32-bit type depending on the platform.

*Changed in version 3.3:* In previous versions, this was a 16-bit type or a 32-bit type depending on whether you selected a “narrow” or “wide” Unicode version of Python at build time.

type PyASCIIObject

type PyCompactUnicodeObject

type PyUnicodeObject

These subtypes of `PyObject` represent a Python Unicode object. In almost all cases, they shouldn’t be used directly, since all API functions that deal with Unicode objects take and return `PyObject` pointers.

*New in version 3.3.*

`PyTypeObject` `PyUnicode_Type`

*Part of the [Stable ABI](#).*

This instance of `PyTypeObject` represents the Python Unicode type. It is exposed to Python code as `str`.

The following APIs are C macros and static inlined functions for fast checks and access to internal read-only data of Unicode objects:

`int PyUnicode_Check(PyObject *o)`

Return true if the object `o` is a Unicode object or an instance of a Unicode subtype. This function always succeeds.

`int PyUnicode_CheckExact(PyObject *o)`

Return true if the object `o` is a Unicode object, but not an instance of a subtype. This function always succeeds.

`int PyUnicode_READY(PyObject *o)`

Returns 0. This API is kept only for backward compatibility.

*New in version 3.3.*

*Deprecated since version 3.10:* This API does nothing since Python 3.12.

`Py_ssize_t PyUnicode_GET_LENGTH(PyObject *o)`

Return the length of the Unicode string, in code points. *o* has to be a Unicode object in the “canonical” representation (not checked).

*New in version 3.3.*

`Py_UCS1 *PyUnicode_1BYTE_DATA(PyObject *o)`

`Py_UCS2 *PyUnicode_2BYTE_DATA(PyObject *o)`

`Py_UCS4 *PyUnicode_4BYTE_DATA(PyObject *o)`

Return a pointer to the canonical representation cast to UCS1, UCS2 or UCS4 integer types for direct character access. No checks are performed if the canonical representation has the correct character size; use `PyUnicode_KIND()` to select the right function.

*New in version 3.3.*

`PyUnicode_1BYTE_KIND`

`PyUnicode_2BYTE_KIND`

`PyUnicode_4BYTE_KIND`

Return values of the `PyUnicode_KIND()` macro.

*New in version 3.3.*

*Changed in version 3.12:* `PyUnicode_WCHAR_KIND` has been removed.

`int PyUnicode_KIND(PyObject *o)`

Return one of the `PyUnicode` kind constants (see above) that indicate how many bytes per character this Unicode object uses to store its data. *o* has to be a Unicode object in the “canonical” representation (not checked).

*New in version 3.3.*

`void *PyUnicode_DATA(PyObject *o)`

Return a void pointer to the raw Unicode buffer. *o* has to be a Unicode object in the “canonical” representation (not checked).

*New in version 3.3.*

`void PyUnicode_WRITE(int kind, void *data, Py_ssize_t index, Py_UCS4 value)`

Write into a canonical representation *data* (as obtained with `PyUnicode_DATA()`). This function performs no sanity checks, and is intended for usage in loops. The caller should cache the *kind* value and *data* pointer as obtained from other calls. *index* is the index in the string (starts at 0) and *value* is the new code point value which should be written to that location.

*New in version 3.3.*

`Py_UCS4 PyUnicode_READ(int kind, void *data, Py_ssize_t index)`

Read a code point from a canonical representation *data* (as obtained with `PyUnicode_DATA()`). No checks or ready calls are performed.

*New in version 3.3.*

`Py_UCS4 PyUnicode_READ_CHAR(PyObject *o, Py_ssize_t index)`

Read a character from a Unicode object *o*, which must be in the “canonical” representation. This is less efficient than `PyUnicode_READ()` if you do multiple consecutive reads.

*New in version 3.3.*

`Py_UCS4 PyUnicode_MAX_CHAR_VALUE(PyObject *o)`

Return the maximum code point that is suitable for creating another string based on *o*, which must be in the “canonical”

representation. This is always an approximation but more efficient than iterating over the string.

*New in version 3.3.*

`int PyUnicode_IsIdentifier(PyObject *o)`

*Part of the [Stable ABI](#).*

Return 1 if the string is a valid identifier according to the language definition, section [Identifiers and keywords](#). Return 0 otherwise.

*Changed in version 3.9:* The function does not call `Py_FatalError()` anymore if the string is not ready.

## Unicode Character Properties

Unicode provides many different character properties. The most often needed ones are available through these macros which are mapped to C functions depending on the Python configuration.

`int Py_UNICODE_ISSPACE(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is a whitespace character.

`int Py_UNICODE_ISLOWER(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is a lowercase character.

`int Py_UNICODE_ISUPPER(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is an uppercase character.

`int Py_UNICODE_ISTITLE(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is a titlecase character.

`int Py_UNICODE_ISLINEBREAK(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is a linebreak character.

`int Py_UNICODE_ISDECIMAL(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is a decimal character.

`int Py_UNICODE_ISDIGIT(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is a digit character.

`int Py_UNICODE_ISNUMERIC(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is a numeric character.

`int Py_UNICODE_ISALPHA(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is an alphabetic character.

`int Py_UNICODE_ISALNUM(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is an alphanumeric character.

`int Py_UNICODE_ISPRINTABLE(Py_UCS4 ch)`

Return 1 or 0 depending on whether *ch* is a printable character. Nonprintable characters are those characters defined in the Unicode character database as “Other” or “Separator”, excepting the ASCII space (0x20) which is considered printable. (Note that printable characters in this context are those which should not be escaped when `repr()` is invoked on a string. It has no bearing on the handling of strings written to `sys.stdout` or `sys.stderr`.)

These APIs can be used for fast direct character conversions:

`Py_UCS4 Py_UNICODE_TOLOWER(Py_UCS4 ch)`

Return the character *ch* converted to lower case.

*Deprecated since version 3.3:* This function uses simple case mappings.

`Py_UCS4 Py_UNICODE_TOUPPER(Py_UCS4 ch)`

Return the character *ch* converted to upper case.

*Deprecated since version 3.3:* This function uses simple case mappings.

`Py_UCS4 Py_UNICODE_TOTITLE(Py_UCS4 ch)`

Return the character *ch* converted to title case.

*Deprecated since version 3.3:* This function uses simple case mappings.

`int Py_UNICODE_TODECIMAL(Py_UCS4 ch)`

Return the character *ch* converted to a decimal positive integer. Return `-1` if this is not possible. This function does not raise exceptions.

`int Py_UNICODE_TODIGIT(Py_UCS4 ch)`

Return the character *ch* converted to a single digit integer. Return `-1` if this is not possible. This function does not raise exceptions.

`double Py_UNICODE_TONUMERIC(Py_UCS4 ch)`

Return the character *ch* converted to a double. Return `-1.0` if this is not possible. This function does not raise exceptions.

These APIs can be used to work with surrogates:

`int Py_UNICODE_IS_SURROGATE(Py_UCS4 ch)`

Check if *ch* is a surrogate (`0xD800 <= ch <= 0xDFFF`).

`int Py_UNICODE_IS_HIGH_SURROGATE(Py_UCS4 ch)`

Check if *ch* is a high surrogate (`0xD800 <= ch <= 0xDBFF`).

int Py\_UNICODE\_IS\_LOW\_SURROGATE(Py\_UCS4 ch)

Check if *ch* is a low surrogate ( $0xDC00 \leq ch \leq 0xDFFF$ ).

Py\_UCS4 Py\_UNICODE\_JOIN\_SURROGATES(Py\_UCS4 high, Py\_UCS4 low)

Join two surrogate characters and return a single **Py\_UCS4** value. *high* and *low* are respectively the leading and trailing surrogates in a surrogate pair. *high* must be in the range [0xD800; 0xDBFF] and *low* must be in the range [0xDC00; 0xDFFF].

## Creating and accessing Unicode strings

To create Unicode objects and access their basic sequence properties, use these APIs:

PyObject \*PyUnicode\_New(Py\_ssize\_t size, Py\_UCS4 maxchar)

*Return value:* New reference.

Create a new Unicode object. *maxchar* should be the true maximum code point to be placed in the string. As an approximation, it can be rounded up to the nearest value in the sequence 127, 255, 65535, 1114111.

This is the recommended way to allocate a new Unicode object. Objects created using this function are not resizable.

*New in version 3.3.*

PyObject \*PyUnicode\_FromKindAndData(int kind, const void \*buffer, Py\_ssize\_t size)

*Return value:* New reference.

Create a new Unicode object with the given *kind* (possible values are **PyUnicode\_1BYTE\_KIND** etc., as returned by **PyUnicode\_KIND()**). The *buffer* must point to an array of *size* units of 1, 2 or 4 bytes per character, as given by the *kind*.

If necessary, the input *buffer* is copied and transformed into

the canonical representation. For example, if the *buffer* is a UCS4 string (`PyUnicode_4BYTE_KIND`) and it consists only of codepoints in the UCS1 range, it will be transformed into UCS1 (`PyUnicode_1BYTE_KIND`).

*New in version 3.3.*

`PyObject *``PyUnicode_FromStringAndSize`(const char \**u*, `Py_ssize_t` *size*)

*Return value:* New reference. Part of the [Stable ABI](#).

Create a Unicode object from the char buffer *u*. The bytes will be interpreted as being UTF-8 encoded. The buffer is copied into the new object. The return value might be a shared object, i.e. modification of the data is not allowed.

This function raises `SystemError` when:

- *size* < 0,
- *u* is `NULL` and *size* > 0

*Changed in version 3.12:* *u* == `NULL` with *size* > 0 is not allowed anymore.

`PyObject *``PyUnicode_FromString`(const char \**u*)

*Return value:* New reference. Part of the [Stable ABI](#).

Create a Unicode object from a UTF-8 encoded null-terminated char buffer *u*.

`PyObject *``PyUnicode_FromFormat`(const char \**format*, ...)

*Return value:* New reference. Part of the [Stable ABI](#).

Take a C `printf()`-style *format* string and a variable number of arguments, calculate the size of the resulting Python Unicode string and return a string with the values formatted into it. The variable arguments must be C types and must correspond exactly to the format characters in the *format* ASCII-encoded string.

A conversion specifier contains two or more characters and has the following components, which must occur in this

order:

1. The `'%'` character, which marks the start of the specifier.
2. Conversion flags (optional), which affect the result of some conversion types.
3. Minimum field width (optional). If specified as an `'*'` (asterisk), the actual width is given in the next argument, which must be of type `int`, and the object to convert comes after the minimum field width and optional precision.
4. Precision (optional), given as a `'.'` (dot) followed by the precision. If specified as `'*'` (an asterisk), the actual precision is given in the next argument, which must be of type `int`, and the value to convert comes after the precision.
5. Length modifier (optional).
6. Conversion type.

The conversion flag characters are:

### **Meaning**

---

The conversion will be zero padded for numeric values.

---

The converted value is left adjusted (overrides the `0` flag if both are given).

---

The length modifiers for following integer conversions (`d`, `i`, `o`, `u`, `x`, or `X`) specify the type of the argument (`int` by default):

### **Modifier**

---

`long` or unsigned long

---

`long long` or unsigned long long

---

`intmax_t` or `uintmax_t`

---

`size_t` or `ssize_t`

---

`ptrdiff_t`

---

The length modifier `l` for following conversions `s` or `v` specify that the type of the argument is `const wchar_t*`.

The conversion specifiers are:

---

## Conversion Specifier

The literal `%` character.

Specified by the `l` length modifier signed C integer.

Specified by the `u` length modifier unsigned C integer.

Specified by the `l` length modifier signed C integer.

Specified by the `l` length modifier of an unsigned C integer (lowercase).

Specified by the `l` length modifier of an unsigned C integer (uppercase).

A single character.

A null-terminated C character array.

The void representation of a C pointer. Mostly equivalent to `printf("%p")` except that it is guaranteed to start with the literal `0x` regardless of what the platform's `printf` yields.

The result of calling `ascii()`.

A Unicode object.

A Unicode object (which may be `char*`) and a null-terminated C character array as a second parameter (which will be used, if the first parameter is `NULL`).

The result of calling `PyObject_Str()`.

The result of calling `PyObject_Repr()`.

## Note

The width formatter unit is number of characters rather than bytes. The precision formatter unit is number of bytes or `wchar_t` items (if the length modifier `l` is used) for `"%s"` and `"%V"` (if the `PyObject*` argument is `NULL`), and a number of characters for `"%A"`, `"%U"`, `"%S"`, `"%R"` and `"%V"` (if the `PyObject*` argument is not `NULL`).

## Note

Unlike to C `printf()` the `0` flag has effect even when a precision is given for integer conversions (`d`, `i`, `u`, `o`, `x`, or `X`).

*Changed in version 3.2:* Support for `"%lld"` and `"%llu"`

added.

*Changed in version 3.3:* Support for "%li", "%lli" and "%zi" added.

*Changed in version 3.4:* Support width and precision formatter for "%s", "%A", "%U", "%V", "%S", "%R" added.

*Changed in version 3.12:* Support for conversion specifiers `o` and `x`. Support for length modifiers `j` and `t`. Length modifiers are now applied to all integer conversions. Length modifier `l` is now applied to conversion specifiers `s` and `v`. Support for variable width and precision `*`. Support for flag `-`.

An unrecognized format character now sets a [SystemError](#). In previous versions it caused all the rest of the format string to be copied as-is to the result string, and any extra arguments discarded.

[PyObject](#) \*PyUnicode\_FromFormatV(const char \*format, va\_list  
vargs)

*Return value:* New reference. Part of the [Stable ABI](#).

Identical to [PyUnicode\\_FromFormat\(\)](#) except that it takes exactly two arguments.

[PyObject](#) \*PyUnicode\_FromObject([PyObject](#) \*obj)

*Return value:* New reference. Part of the [Stable ABI](#).

Copy an instance of a Unicode subtype to a new true Unicode object if necessary. If *obj* is already a true Unicode object (not a subtype), return a new [strong reference](#) to the object.

Objects other than Unicode or its subtypes will cause a [TypeError](#).

[PyObject](#) \*PyUnicode\_FromEncodedObject([PyObject](#) \*obj, const  
char \*encoding, const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#).

Decode an encoded object *obj* to a Unicode object.

`bytes`, `bytearray` and other `bytes-like objects` are decoded according to the given *encoding* and using the error handling defined by *errors*. Both can be `NULL` to have the interface use the default values (see `Built-in Codecs` for details).

All other objects, including Unicode objects, cause a `TypeError` to be set.

The API returns `NULL` if there was an error. The caller is responsible for decrementing the returned objects.

`Py_ssize_t` PyUnicode\_GetLength(`PyObject *`unicode)

Part of the *Stable ABI* since version 3.7.

Return the length of the Unicode object, in code points.

*New in version 3.3.*

`Py_ssize_t` PyUnicode\_CopyCharacters(`PyObject *`to, `Py_ssize_t` to\_start, `PyObject *`from, `Py_ssize_t` from\_start, `Py_ssize_t` how\_many)

Copy characters from one Unicode object into another. This function performs character conversion when necessary and falls back to `memcpy()` if possible. Returns `-1` and sets an exception on error, otherwise returns the number of copied characters.

*New in version 3.3.*

`Py_ssize_t` PyUnicode\_Fill(`PyObject *`unicode, `Py_ssize_t` start, `Py_ssize_t` length, `Py_UCS4` fill\_char)

Fill a string with a character: write *fill\_char* into `unicode[start:start+length]`.

Fail if *fill\_char* is bigger than the string maximum character, or if the string has more than 1 reference.

Return the number of written character, or return `-1` and raise an exception on error.

*New in version 3.3.*

int PyUnicode\_WriteChar(PyObject \*unicode, Py\_ssize\_t index, Py\_UCS4 character)

*Part of the [Stable ABI](#) since version 3.7.*

Write a character to a string. The string must have been created through [PyUnicode\\_New\(\)](#). Since Unicode strings are supposed to be immutable, the string must not be shared, or have been hashed yet.

This function checks that *unicode* is a Unicode object, that the index is not out of bounds, and that the object can be modified safely (i.e. that its reference count is one).

*New in version 3.3.*

Py\_UCS4 PyUnicode\_ReadChar(PyObject \*unicode, Py\_ssize\_t index)

*Part of the [Stable ABI](#) since version 3.7.*

Read a character from a string. This function checks that *unicode* is a Unicode object and the index is not out of bounds, in contrast to [PyUnicode\\_READ\\_CHAR\(\)](#), which performs no error checking.

*New in version 3.3.*

PyObject \*PyUnicode\_Substring(PyObject \*str, Py\_ssize\_t start, Py\_ssize\_t end)

*Return value: New reference. Part of the [Stable ABI](#) since version 3.7.*

Return a substring of *str*, from character index *start* (included) to character index *end* (excluded). Negative indices are not supported.

*New in version 3.3.*

Py\_UCS4 \*PyUnicode\_AsUCS4(PyObject \*u, Py\_UCS4 \*buffer, Py\_ssize\_t buflen, int copy\_null)

*Part of the [Stable ABI](#) since version 3.7.*

Copy the string *u* into a UCS4 buffer, including a null character, if *copy\_null* is set. Returns `NULL` and sets an

exception on error (in particular, a `SystemError` if `buflen` is smaller than the length of `u`). `buffer` is returned on success.

*New in version 3.3.*

`Py_UCS4 *PyUnicode_AsUCS4Copy(PyObject *u)`

Part of the *Stable ABI* since version 3.7.

Copy the string `u` into a new UCS4 buffer that is allocated using `PyMem_Malloc()`. If this fails, `NULL` is returned with a `MemoryError` set. The returned buffer always has an extra null code point appended.

*New in version 3.3.*

## Locale Encoding

The current locale encoding can be used to decode text from the operating system.

`PyObject *PyUnicode_DecodeLocaleAndSize(const char *str, Py_ssize_t len, const char *errors)`

*Return value:* New reference. Part of the *Stable ABI* since version 3.7.

Decode a string from UTF-8 on Android and VxWorks, or from the current locale encoding on other platforms. The supported error handlers are "strict" and "surrogateescape" ([PEP 383](https://peps.python.org/pep-0383/) [https://peps.python.org/pep-0383/]). The decoder uses "strict" error handler if `errors` is `NULL`. `str` must end with a null character but cannot contain embedded null characters.

Use `PyUnicode_DecodeFSDefaultAndSize()` to decode a string from the [filesystem encoding and error handler](#).

This function ignores the [Python UTF-8 Mode](#).

**See also**

The `Py_DecodeLocale()` function.

*New in version 3.3.*

*Changed in version 3.7:* The function now also uses the current locale encoding for the `surrogateescape` error handler, except on Android. Previously, `Py_DecodeLocale()` was used for the `surrogateescape`, and the current locale encoding was used for `strict`.

**PyObject** \*PyUnicode\_DecodeLocale(const char \*str, const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#) since version 3.7.

Similar to `PyUnicode_DecodeLocaleAndSize()`, but compute the string length using `strlen()`.

*New in version 3.3.*

**PyObject** \*PyUnicode\_EncodeLocale(PyObject \*unicode, const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#) since version 3.7.

Encode a Unicode object to UTF-8 on Android and VxWorks, or to the current locale encoding on other platforms. The supported error handlers are "strict" and "surrogateescape" ([PEP 383](#) [<https://peps.python.org/pep-0383/>]). The encoder uses "strict" error handler if `errors` is NULL. Return a **bytes** object. `unicode` cannot contain embedded null characters.

Use `PyUnicode_EncodeFSDefault()` to encode a string to the [filesystem encoding and error handler](#).

This function ignores the [Python UTF-8 Mode](#).

**See also**

The `Py_EncodeLocale()` function.

*New in version 3.3.*

*Changed in version 3.7:* The function now also uses the current locale encoding for the `surrogateescape` error handler, except on Android. Previously, `Py_EncodeLocale()` was used for the `surrogateescape`, and the current locale encoding was used for `strict`.

## File System Encoding

Functions encoding to and decoding from the [filesystem encoding and error handler](#) (PEP 383 [https://peps.python.org/pep-0383/] and PEP 529 [https://peps.python.org/pep-0529/]).

To encode file names to `bytes` during argument parsing, the `"O&"` converter should be used, passing `PyUnicode_FSConverter()` as the conversion function:

```
int PyUnicode_FSConverter(PyObject *obj, void *result)
```

*Part of the [Stable ABI](#).*

ParseTuple converter: encode `str` objects – obtained directly or through the `os.PathLike` interface – to `bytes` using `PyUnicode_EncodeFSDefault()`; `bytes` objects are output as-is. *result* must be a `PyBytesObject*` which must be released when it is no longer used.

*New in version 3.1.*

*Changed in version 3.6:* Accepts a [path-like object](#).

To decode file names to `str` during argument parsing, the `"O&"` converter should be used, passing `PyUnicode_FSDecoder()` as the conversion function:

```
int PyUnicode_FSDecoder(PyObject *obj, void *result)
```

*Part of the [Stable ABI](#).*

ParseTuple converter: decode `bytes` objects – obtained either directly or indirectly through the `os.PathLike` interface – to `str` using `PyUnicode_DecodeFSDefaultAndSize()`; `str` objects are output as-is. *result* must be a `PyUnicodeObject*` which must be released when it is no longer used.

*New in version 3.2.*

*Changed in version 3.6:* Accepts a [path-like object](#).

**PyObject** \*PyUnicode\_DecodeFSDefaultAndSize(const char \*s,  
**Py\_ssize\_t** size)

*Return value:* New reference. Part of the [Stable ABI](#).

Decode a string from the [filesystem encoding and error handler](#).

If you need to decode a string from the current locale encoding, use [PyUnicode\\_DecodeLocaleAndSize\(\)](#).

### See also

The [Py\\_DecodeLocale\(\)](#) function.

*Changed in version 3.6:* The [filesystem error handler](#) is now used.

**PyObject** \*PyUnicode\_DecodeFSDefault(const char \*s)

*Return value:* New reference. Part of the [Stable ABI](#).

Decode a null-terminated string from the [filesystem encoding and error handler](#).

If the string length is known, use  
[PyUnicode\\_DecodeFSDefaultAndSize\(\)](#).

*Changed in version 3.6:* The [filesystem error handler](#) is now used.

**PyObject** \*PyUnicode\_EncodeFSDefault(**PyObject** \*unicode)

*Return value:* New reference. Part of the [Stable ABI](#).

Encode a Unicode object to the [filesystem encoding and error handler](#), and return **bytes**. Note that the resulting **bytes** object can contain null bytes.

If you need to encode a string to the current locale encoding, use [PyUnicode\\_EncodeLocale\(\)](#).

See also

The `Py_EncodeLocale()` function.

*New in version 3.2.*

*Changed in version 3.6:* The [filesystem error handler](#) is now used.

## wchar\_t Support

**wchar\_t** support for platforms which support it:

**PyObject** \*PyUnicode\_FromWideChar(const wchar\_t \*w, Py\_ssize\_t size)

*Return value:* New reference. Part of the [Stable ABI](#).

Create a Unicode object from the **wchar\_t** buffer *w* of the given *size*. Passing `-1` as the *size* indicates that the function must itself compute the length, using `wcslen`. Return `NULL` on failure.

**Py\_ssize\_t** PyUnicode\_AsWideChar(**PyObject** \*unicode, wchar\_t \*w, **Py\_ssize\_t** size)

*Part of the [Stable ABI](#).*

Copy the Unicode object contents into the **wchar\_t** buffer *w*. At most *size* **wchar\_t** characters are copied (excluding a possibly trailing null termination character). Return the number of **wchar\_t** characters copied or `-1` in case of an error. Note that the resulting **wchar\_t**\* string may or may not be null-terminated. It is the responsibility of the caller to make sure that the **wchar\_t**\* string is null-terminated in case this is required by the application. Also, note that the **wchar\_t**\* string might contain null characters, which would cause the string to be truncated when used with most C functions.

**wchar\_t** \*PyUnicode\_AsWideCharString(**PyObject** \*unicode, **Py\_ssize\_t** \*size)

Part of the *Stable ABI* since version 3.7.

Convert the Unicode object to a wide character string. The output string always ends with a null character. If *size* is not `NULL`, write the number of wide characters (excluding the trailing null termination character) into *\*size*. Note that the resulting `wchar_t` string might contain null characters, which would cause the string to be truncated when used with most C functions. If *size* is `NULL` and the `wchar_t*` string contains null characters a `ValueError` is raised.

Returns a buffer allocated by `PyMem_New` (use `PyMem_Free()` to free it) on success. On error, returns `NULL` and *\*size* is undefined. Raises a `MemoryError` if memory allocation is failed.

*New in version 3.2.*

*Changed in version 3.7:* Raises a `ValueError` if *size* is `NULL` and the `wchar_t*` string contains null characters.

## Built-in Codecs

Python provides a set of built-in codecs which are written in C for speed. All of these codecs are directly usable via the following functions.

Many of the following APIs take two arguments encoding and errors, and they have the same semantics as the ones of the built-in `str()` string object constructor.

Setting encoding to `NULL` causes the default encoding to be used which is UTF-8. The file system calls should use `PyUnicode_FSConverter()` for encoding file names. This uses the `filesystem encoding and error handler` internally.

Error handling is set by errors which may also be set to `NULL` meaning to use the default handling defined for the codec. Default error handling for all built-in codecs is “strict” (`ValueError` is raised).

The codecs all use a similar interface. Only deviations from the following generic ones are documented for simplicity.

## Generic Codecs

These are the generic codec APIs:

**PyObject \***PyUnicode\_Decode(const char \*s, **Py\_ssize\_t** size, const char \*encoding, const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#).

Create a Unicode object by decoding *size* bytes of the encoded string *s*. *encoding* and *errors* have the same meaning as the parameters of the same name in the [str\(\)](#) built-in function. The codec to be used is looked up using the Python codec registry. Return `NULL` if an exception was raised by the codec.

**PyObject \***PyUnicode\_AsEncodedString(**PyObject \***unicode, const char \*encoding, const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#).

Encode a Unicode object and return the result as Python bytes object. *encoding* and *errors* have the same meaning as the parameters of the same name in the Unicode [encode\(\)](#) method. The codec to be used is looked up using the Python codec registry. Return `NULL` if an exception was raised by the codec.

## UTF-8 Codecs

These are the UTF-8 codec APIs:

**PyObject \***PyUnicode\_DecodeUTF8(const char \*s, **Py\_ssize\_t** size, const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#).

Create a Unicode object by decoding *size* bytes of the UTF-8 encoded string *s*. Return `NULL` if an exception was raised by the codec.

`PyObject *PyUnicode_DecodeUTF8Stateful(const char *s, Py_ssize_t size, const char *errors, Py_ssize_t *consumed)`

*Return value:* New reference. Part of the [Stable ABI](#).

If *consumed* is `NULL`, behave like

`PyUnicode_DecodeUTF8()`. If *consumed* is not `NULL`, trailing incomplete UTF-8 byte sequences will not be treated as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in *consumed*.

`PyObject *PyUnicode_AsUTF8String(PyObject *unicode)`

*Return value:* New reference. Part of the [Stable ABI](#).

Encode a Unicode object using UTF-8 and return the result as Python bytes object. Error handling is “strict”. Return `NULL` if an exception was raised by the codec.

`const char *PyUnicode_AsUTF8AndSize(PyObject *unicode, Py_ssize_t *size)`

Part of the [Stable ABI](#) since version 3.10.

Return a pointer to the UTF-8 encoding of the Unicode object, and store the size of the encoded representation (in bytes) in *size*. The *size* argument can be `NULL`; in this case no size will be stored. The returned buffer always has an extra null byte appended (not included in *size*), regardless of whether there are any other null code points.

In the case of an error, `NULL` is returned with an exception set and no *size* is stored.

This caches the UTF-8 representation of the string in the Unicode object, and subsequent calls will return a pointer to the same buffer. The caller is not responsible for deallocating the buffer. The buffer is deallocated and pointers to it become invalid when the Unicode object is garbage collected.

*New in version 3.3.*

*Changed in version 3.7:* The return type is now `const char *` rather of `char *`.

*Changed in version 3.10:* This function is a part of the [limited API](#).

`const char *PyUnicode_AsUTF8(PyObject *unicode)`

As `PyUnicode_AsUTF8AndSize()`, but does not store the size.

*New in version 3.3.*

*Changed in version 3.7:* The return type is now `const char *` rather of `char *`.

## UTF-32 Codecs

These are the UTF-32 codec APIs:

`PyObject *PyUnicode_DecodeUTF32(const char *s, Py_ssize_t size, const char *errors, int *byteorder)`

*Return value:* New reference. Part of the [Stable ABI](#).

Decode *size* bytes from a UTF-32 encoded buffer string and return the corresponding Unicode object. *errors* (if non-NULL) defines the error handling. It defaults to “strict”.

If *byteorder* is non-NULL, the decoder starts decoding using the given byte order:

`*byteorder == -1: little endian`

`*byteorder == 0: native order`

`*byteorder == 1: big endian`

If *\*byteorder* is zero, and the first four bytes of the input data are a byte order mark (BOM), the decoder switches to this byte order and the BOM is not copied into the resulting Unicode string. If *\*byteorder* is `-1` or `1`, any byte order mark is copied to the output.

After completion, *\*byteorder* is set to the current byte order at the end of input data.

If *byteorder* is NULL, the codec starts in native order mode.

Return `NULL` if an exception was raised by the codec.

`PyObject *``PyUnicode_DecodeUTF32Stateful`(`const char *s`,  
`Py_ssize_t size`, `const char *errors`, `int *byteorder`, `Py_ssize_t`  
`*consumed`)

*Return value: New reference. Part of the [Stable ABI](#).*

If `consumed` is `NULL`, behave like

`PyUnicode_DecodeUTF32()`. If `consumed` is not `NULL`,  
`PyUnicode_DecodeUTF32Stateful()` will not treat  
trailing incomplete UTF-32 byte sequences (such as a number  
of bytes not divisible by four) as an error. Those bytes will  
not be decoded and the number of bytes that have been  
decoded will be stored in *consumed*.

`PyObject *``PyUnicode_AsUTF32String`(`PyObject *``unicode`)

*Return value: New reference. Part of the [Stable ABI](#).*

Return a Python byte string using the UTF-32 encoding in  
native byte order. The string always starts with a BOM mark.  
Error handling is “strict”. Return `NULL` if an exception was  
raised by the codec.

## UTF-16 Codecs

These are the UTF-16 codec APIs:

`PyObject *``PyUnicode_DecodeUTF16`(`const char *s`, `Py_ssize_t size`,  
`const char *errors`, `int *byteorder`)

*Return value: New reference. Part of the [Stable ABI](#).*

Decode *size* bytes from a UTF-16 encoded buffer string and  
return the corresponding Unicode object. *errors* (if non-`NULL`)  
defines the error handling. It defaults to “strict”.

If *byteorder* is non-`NULL`, the decoder starts decoding using  
the given byte order:

```
*byteorder == -1: little endian  
*byteorder == 0:  native order  
*byteorder == 1:  big endian
```

If `*byteorder` is zero, and the first two bytes of the input data are a byte order mark (BOM), the decoder switches to this byte order and the BOM is not copied into the resulting Unicode string. If `*byteorder` is `-1` or `1`, any byte order mark is copied to the output (where it will result in either a `\uffeff` or a `\ufffe` character).

After completion, `*byteorder` is set to the current byte order at the end of input data.

If `byteorder` is `NULL`, the codec starts in native order mode.

Return `NULL` if an exception was raised by the codec.

**PyObject** \*PyUnicode\_DecodeUTF16Stateful(const char \*s, Py\_ssize\_t size, const char \*errors, int \*byteorder, Py\_ssize\_t \*consumed)

*Return value:* New reference. Part of the [Stable ABI](#).

If *consumed* is `NULL`, behave like

**PyUnicode\_DecodeUTF16()**. If *consumed* is not `NULL`, **PyUnicode\_DecodeUTF16Stateful()** will not treat trailing incomplete UTF-16 byte sequences (such as an odd number of bytes or a split surrogate pair) as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in *consumed*.

**PyObject** \*PyUnicode\_AsUTF16String(PyObject \*unicode)

*Return value:* New reference. Part of the [Stable ABI](#).

Return a Python byte string using the UTF-16 encoding in native byte order. The string always starts with a BOM mark. Error handling is “strict”. Return `NULL` if an exception was raised by the codec.

## UTF-7 Codecs

These are the UTF-7 codec APIs:

**PyObject** \*PyUnicode\_DecodeUTF7(const char \*s, Py\_ssize\_t size, const char \*errors)

*Return value: New reference. Part of the [Stable ABI](#).*

Create a Unicode object by decoding *size* bytes of the UTF-7 encoded string *s*. Return `NULL` if an exception was raised by the codec.

**PyObject \***PyUnicode\_DecodeUTF7Stateful(const char \*s, **Py\_ssize\_t** size, const char \*errors, **Py\_ssize\_t** \*consumed)

*Return value: New reference. Part of the [Stable ABI](#).*

If *consumed* is `NULL`, behave like

**PyUnicode\_DecodeUTF7()**. If *consumed* is not `NULL`, trailing incomplete UTF-7 base-64 sections will not be treated as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in *consumed*.

## Unicode-Escape Codecs

These are the “Unicode Escape” codec APIs:

**PyObject \***PyUnicode\_DecodeUnicodeEscape(const char \*s, **Py\_ssize\_t** size, const char \*errors)

*Return value: New reference. Part of the [Stable ABI](#).*

Create a Unicode object by decoding *size* bytes of the Unicode-Escape encoded string *s*. Return `NULL` if an exception was raised by the codec.

**PyObject \***PyUnicode\_AsUnicodeEscapeString(**PyObject \***unicode)

*Return value: New reference. Part of the [Stable ABI](#).*

Encode a Unicode object using Unicode-Escape and return the result as a bytes object. Error handling is “strict”. Return `NULL` if an exception was raised by the codec.

## Raw-Unicode-Escape Codecs

These are the “Raw Unicode Escape” codec APIs:

**PyObject \***PyUnicode\_DecodeRawUnicodeEscape(const char \*s, **Py\_ssize\_t** size, const char \*errors)

*Return value: New reference. Part of the [Stable ABI](#).*

Create a Unicode object by decoding *size* bytes of the Raw-Unicode-Escape encoded string *s*. Return `NULL` if an exception was raised by the codec.

**PyObject** \*PyUnicode\_AsRawUnicodeEscapeString(**PyObject** \*unicode)

*Return value: New reference. Part of the [Stable ABI](#).*

Encode a Unicode object using Raw-Unicode-Escape and return the result as a bytes object. Error handling is “strict”. Return `NULL` if an exception was raised by the codec.

## Latin-1 Codecs

These are the Latin-1 codec APIs: Latin-1 corresponds to the first 256 Unicode ordinals and only these are accepted by the codecs during encoding.

**PyObject** \*PyUnicode\_DecodeLatin1(const char \*s, **Py\_ssize\_t** size, const char \*errors)

*Return value: New reference. Part of the [Stable ABI](#).*

Create a Unicode object by decoding *size* bytes of the Latin-1 encoded string *s*. Return `NULL` if an exception was raised by the codec.

**PyObject** \*PyUnicode\_AsLatin1String(**PyObject** \*unicode)

*Return value: New reference. Part of the [Stable ABI](#).*

Encode a Unicode object using Latin-1 and return the result as Python bytes object. Error handling is “strict”. Return `NULL` if an exception was raised by the codec.

## ASCII Codecs

These are the ASCII codec APIs. Only 7-bit ASCII data is accepted. All other codes generate errors.

**PyObject** \*PyUnicode\_DecodeASCII(const char \*s, **Py\_ssize\_t** size,

const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#).

Create a Unicode object by decoding *size* bytes of the ASCII encoded string *s*. Return `NULL` if an exception was raised by the codec.

[PyObject](#) \*PyUnicode\_AsASCIIString([PyObject](#) \*unicode)

*Return value:* New reference. Part of the [Stable ABI](#).

Encode a Unicode object using ASCII and return the result as Python bytes object. Error handling is “strict”. Return `NULL` if an exception was raised by the codec.

## Character Map Codecs

This codec is special in that it can be used to implement many different codecs (and this is in fact what was done to obtain most of the standard codecs included in the **encodings** package). The codec uses mappings to encode and decode characters. The mapping objects provided must support the [\\_\\_getitem\\_\\_\(\)](#) mapping interface; dictionaries and sequences work well.

These are the mapping codec APIs:

[PyObject](#) \*PyUnicode\_DecodeCharmap(const char \*data, [Py\\_ssize\\_t](#) size, [PyObject](#) \*mapping, const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#).

Create a Unicode object by decoding *size* bytes of the encoded string *s* using the given *mapping* object. Return `NULL` if an exception was raised by the codec.

If *mapping* is `NULL`, Latin-1 decoding will be applied. Else *mapping* must map bytes ordinals (integers in the range from 0 to 255) to Unicode strings, integers (which are then interpreted as Unicode ordinals) or `None`. Unmapped data bytes – ones which cause a [LookupError](#), as well as ones which get mapped to `None`, `0xFFFE` or `'\ufffe'`, are treated as undefined mappings and cause an error.

`PyObject *PyUnicode_AsCharmapString(PyObject *unicode,  
PyObject *mapping)`

*Return value: New reference. Part of the [Stable ABI](#).*

Encode a Unicode object using the given *mapping* object and return the result as a bytes object. Error handling is “strict”.

Return `NULL` if an exception was raised by the codec.

The *mapping* object must map Unicode ordinal integers to bytes objects, integers in the range from 0 to 255 or `None`. Unmapped character ordinals (ones which cause a [LookupError](#)) as well as mapped to `None` are treated as “undefined mapping” and cause an error.

The following codec API is special in that maps Unicode to Unicode.

`PyObject *PyUnicode_Translate(PyObject *str, PyObject *table,  
const char *errors)`

*Return value: New reference. Part of the [Stable ABI](#).*

Translate a string by applying a character mapping table to it and return the resulting Unicode object. Return `NULL` if an exception was raised by the codec.

The mapping table must map Unicode ordinal integers to Unicode ordinal integers or `None` (causing deletion of the character).

Mapping tables need only provide the `__getitem__()` interface; dictionaries and sequences work well. Unmapped character ordinals (ones which cause a [LookupError](#)) are left untouched and are copied as-is.

*errors* has the usual meaning for codecs. It may be `NULL` which indicates to use the default error handling.

## MBCS codecs for Windows

These are the MBCS codec APIs. They are currently only available on Windows and use the Win32 MBCS converters to implement the conversions. Note that MBCS (or DBCS) is a class of encodings, not

just one. The target encoding is defined by the user settings on the machine running the codec.

**PyObject \***PyUnicode\_DecodeMBCS(const char \*s, **Py\_ssize\_t** size, const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#) on Windows since version 3.7.

Create a Unicode object by decoding *size* bytes of the MBCS encoded string *s*. Return `NULL` if an exception was raised by the codec.

**PyObject \***PyUnicode\_DecodeMBCSStateful(const char \*s, **Py\_ssize\_t** size, const char \*errors, **Py\_ssize\_t** \*consumed)

*Return value:* New reference. Part of the [Stable ABI](#) on Windows since version 3.7.

If *consumed* is `NULL`, behave like

**PyUnicode\_DecodeMBCS()**. If *consumed* is not `NULL`, **PyUnicode\_DecodeMBCSStateful()** will not decode trailing lead byte and the number of bytes that have been decoded will be stored in *consumed*.

**PyObject \***PyUnicode\_AsMBCSString(**PyObject \***unicode)

*Return value:* New reference. Part of the [Stable ABI](#) on Windows since version 3.7.

Encode a Unicode object using MBCS and return the result as Python bytes object. Error handling is “strict”. Return `NULL` if an exception was raised by the codec.

**PyObject \***PyUnicode\_EncodeCodePage(int code\_page, **PyObject \***unicode, const char \*errors)

*Return value:* New reference. Part of the [Stable ABI](#) on Windows since version 3.7.

Encode the Unicode object using the specified code page and return a Python bytes object. Return `NULL` if an exception was raised by the codec. Use **CP\_ACP** code page to get the MBCS encoder.

*New in version 3.3.*

## Methods & Slots

# Methods and Slot Functions

The following APIs are capable of handling Unicode objects and strings on input (we refer to them as strings in the descriptions) and return Unicode objects or integers as appropriate.

They all return `NULL` or `-1` if an exception occurs.

`PyObject *PyUnicode_Concat(PyObject *left, PyObject *right)`

*Return value: New reference. Part of the [Stable ABI](#).*

Concat two strings giving a new Unicode string.

`PyObject *PyUnicode_Split(PyObject *s, PyObject *sep, Py_ssize_t maxsplit)`

*Return value: New reference. Part of the [Stable ABI](#).*

Split a string giving a list of Unicode strings. If *sep* is `NULL`, splitting will be done at all whitespace substrings. Otherwise, splits occur at the given separator. At most *maxsplit* splits will be done. If negative, no limit is set. Separators are not included in the resulting list.

`PyObject *PyUnicode_Splitlines(PyObject *s, int keepend)`

*Return value: New reference. Part of the [Stable ABI](#).*

Split a Unicode string at line breaks, returning a list of Unicode strings. CRLF is considered to be one line break. If *keepend* is `0`, the line break characters are not included in the resulting strings.

`PyObject *PyUnicode_Join(PyObject *separator, PyObject *seq)`

*Return value: New reference. Part of the [Stable ABI](#).*

Join a sequence of strings using the given *separator* and return the resulting Unicode string.

`Py_ssize_t PyUnicode_Tailmatch(PyObject *str, PyObject *substr, Py_ssize_t start, Py_ssize_t end, int direction)`

Part of the *Stable ABI*.

Return 1 if *substr* matches `str[start:end]` at the given tail end (*direction* == -1 means to do a prefix match, *direction* == 1 a suffix match), 0 otherwise. Return -1 if an error occurred.

`Py_ssize_t PyUnicode_Find(PyObject *str, PyObject *substr,  
Py_ssize_t start, Py_ssize_t end, int direction)`

Part of the *Stable ABI*.

Return the first position of *substr* in `str[start:end]` using the given *direction* (*direction* == 1 means to do a forward search, *direction* == -1 a backward search). The return value is the index of the first match; a value of -1 indicates that no match was found, and -2 indicates that an error occurred and an exception has been set.

`Py_ssize_t PyUnicode_FindChar(PyObject *str, Py_UCS4 ch,  
Py_ssize_t start, Py_ssize_t end, int direction)`

Part of the *Stable ABI* since version 3.7.

Return the first position of the character *ch* in `str[start:end]` using the given *direction* (*direction* == 1 means to do a forward search, *direction* == -1 a backward search). The return value is the index of the first match; a value of -1 indicates that no match was found, and -2 indicates that an error occurred and an exception has been set.

*New in version 3.3.*

*Changed in version 3.7:* *start* and *end* are now adjusted to behave like `str[start:end]`.

`Py_ssize_t PyUnicode_Count(PyObject *str, PyObject *substr,  
Py_ssize_t start, Py_ssize_t end)`

Part of the *Stable ABI*.

Return the number of non-overlapping occurrences of *substr* in `str[start:end]`. Return -1 if an error occurred.

`PyObject *PyUnicode_Replace(PyObject *str, PyObject *substr, PyObject *replstr, Py_ssize_t maxcount)`

*Return value:* New reference. Part of the [Stable ABI](#).

Replace at most *maxcount* occurrences of *substr* in *str* with *replstr* and return the resulting Unicode object. *maxcount* = -1 means replace all occurrences.

`int PyUnicode_Compare(PyObject *left, PyObject *right)`

*Part of the [Stable ABI](#).*

Compare two strings and return -1, 0, 1 for less than, equal, and greater than, respectively.

This function returns -1 upon failure, so one should call `PyErr_Occurred()` to check for errors.

`int PyUnicode_CompareWithASCIIString(PyObject *uni, const char *string)`

*Part of the [Stable ABI](#).*

Compare a Unicode object, *uni*, with *string* and return -1, 0, 1 for less than, equal, and greater than, respectively. It is best to pass only ASCII-encoded strings, but the function interprets the input string as ISO-8859-1 if it contains non-ASCII characters.

This function does not raise exceptions.

`PyObject *PyUnicode_RichCompare(PyObject *left, PyObject *right, int op)`

*Return value:* New reference. Part of the [Stable ABI](#).

Rich compare two Unicode strings and return one of the following:

- NULL in case an exception was raised
- `Py_True` or `Py_False` for successful comparisons
- `Py_NotImplemented` in case the type combination is unknown

Possible values for *op* are `Py_GT`, `Py_GE`, `Py_EQ`, `Py_NE`,

**Py\_LT**, and **Py\_LE**.

**PyObject** \*PyUnicode\_Format(**PyObject** \*format, **PyObject** \*args)

*Return value:* New reference. Part of the [Stable ABI](#).

Return a new string object from *format* and *args*; this is analogous to `format % args`.

int PyUnicode\_Contains(**PyObject** \*container, **PyObject** \*element)

*Part of the [Stable ABI](#).*

Check whether *element* is contained in *container* and return true or false accordingly.

*element* has to coerce to a one element Unicode string. -1 is returned if there was an error.

void PyUnicode\_InternInPlace(**PyObject** \*\*string)

*Part of the [Stable ABI](#).*

Intern the argument *\*string* in place. The argument must be the address of a pointer variable pointing to a Python Unicode string object. If there is an existing interned string that is the same as *\*string*, it sets *\*string* to it (releasing the reference to the old string object and creating a new [strong reference](#) to the interned string object), otherwise it leaves *\*string* alone and interns it (creating a new [strong reference](#)). (Clarification: even though there is a lot of talk about references, think of this function as reference-neutral; you own the object after the call if and only if you owned it before the call.)

**PyObject** \*PyUnicode\_InternFromString(const char \*v)

*Return value:* New reference. Part of the [Stable ABI](#).

A combination of [PyUnicode\\_FromString\(\)](#) and [PyUnicode\\_InternInPlace\(\)](#), returning either a new Unicode string object that has been interned, or a new (“owned”) reference to an earlier interned string object with the same value.

# Tuple Objects

type PyTupleObject

This subtype of `PyObject` represents a Python tuple object.

`PyTypeObject` PyTuple\_Type

*Part of the [Stable ABI](#).*

This instance of `PyTypeObject` represents the Python tuple type; it is the same object as `tuple` in the Python layer.

int PyTuple\_Check(`PyObject` \*p)

Return true if *p* is a tuple object or an instance of a subtype of the tuple type. This function always succeeds.

int PyTuple\_CheckExact(`PyObject` \*p)

Return true if *p* is a tuple object, but not an instance of a subtype of the tuple type. This function always succeeds.

`PyObject` \*PyTuple\_New(`Py_ssize_t` len)

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new tuple object of size *len*, or `NULL` on failure.

`PyObject` \*PyTuple\_Pack(`Py_ssize_t` n, ...)

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new tuple object of size *n*, or `NULL` on failure. The tuple values are initialized to the subsequent *n* C arguments pointing to Python objects. `PyTuple_Pack(2, a, b)` is equivalent to `Py_BuildValue("(OO)", a, b)`.

`Py_ssize_t` PyTuple\_Size(`PyObject` \*p)

*Part of the [Stable ABI](#).*

Take a pointer to a tuple object, and return the size of that

tuple.

`Py_ssize_t PyTuple_GET_SIZE(PyObject *p)`

Return the size of the tuple *p*, which must be non-NULL and point to a tuple; no error checking is performed.

`PyObject *PyTuple_GetItem(PyObject *p, Py_ssize_t pos)`

*Return value:* Borrowed reference. Part of the *Stable ABI*.

Return the object at position *pos* in the tuple pointed to by *p*. If *pos* is negative or out of bounds, return NULL and set an **IndexError** exception.

`PyObject *PyTuple_GET_ITEM(PyObject *p, Py_ssize_t pos)`

*Return value:* Borrowed reference.

Like `PyTuple_GetItem()`, but does no checking of its arguments.

`PyObject *PyTuple_GetSlice(PyObject *p, Py_ssize_t low, Py_ssize_t high)`

*Return value:* New reference. Part of the *Stable ABI*.

Return the slice of the tuple pointed to by *p* between *low* and *high*, or NULL on failure. This is the equivalent of the Python expression `p[low:high]`. Indexing from the end of the tuple is not supported.

`int PyTuple_SetItem(PyObject *p, Py_ssize_t pos, PyObject *o)`

*Part of the Stable ABI.*

Insert a reference to object *o* at position *pos* of the tuple pointed to by *p*. Return 0 on success. If *pos* is out of bounds, return -1 and set an **IndexError** exception.

## Note

This function “steals” a reference to *o* and discards a reference to an item already in the tuple at the affected position.

`void PyTuple_SET_ITEM(PyObject *p, Py_ssize_t pos, PyObject *o)`

Like `PyTuple_SetItem()`, but does no error checking, and should *only* be used to fill in brand new tuples.

### Note

This function “steals” a reference to *o*, and, unlike `PyTuple_SetItem()`, does *not* discard a reference to any item that is being replaced; any reference in the tuple at position *pos* will be leaked.

`int _PyTuple_Resize(PyObject **p, Py_ssize_t newsize)`

Can be used to resize a tuple. *newsize* will be the new length of the tuple. Because tuples are *supposed* to be immutable, this should only be used if there is only one reference to the object. Do *not* use this if the tuple may already be known to some other part of the code. The tuple will always grow or shrink at the end. Think of this as destroying the old tuple and creating a new one, only more efficiently. Returns 0 on success. Client code should never assume that the resulting value of *\*p* will be the same as before calling this function. If the object referenced by *\*p* is replaced, the original *\*p* is destroyed. On failure, returns -1 and sets *\*p* to NULL, and raises `MemoryError` or `SystemError`.

## Struct Sequence Objects

Struct sequence objects are the C equivalent of `namedtuple()` objects, i.e. a sequence whose items can also be accessed through attributes. To create a struct sequence, you first have to create a specific struct sequence type.

`PyTypeObject *PyStructSequence_NewType(PyStructSequence_Desc *desc)`

*Return value: New reference. Part of the [Stable ABI](#).*

Create a new struct sequence type from the data in *desc*, described below. Instances of the resulting type can be created with `PyStructSequence_New()`.

```
void PyStructSequence_InitType(PyTypeObject *type,  
PyStructSequence_Desc *desc)
```

Initializes a struct sequence type *type* from *desc* in place.

```
int PyStructSequence_InitType2(PyTypeObject *type,  
PyStructSequence_Desc *desc)
```

The same as `PyStructSequence_InitType`, but returns 0 on success and -1 on failure.

*New in version 3.4.*

```
type PyStructSequence_Desc
```

*Part of the [Stable ABI](#) (including all members).*

Contains the meta information of a struct sequence type to create.

```
const char *name
```

Name of the struct sequence type.

```
const char *doc
```

Pointer to docstring for the type or `NULL` to omit.

```
PyStructSequence_Field *fields
```

Pointer to `NULL`-terminated array with field names of the new type.

```
int n_in_sequence
```

Number of fields visible to the Python side (if used as tuple).

```
type PyStructSequence_Field
```

*Part of the [Stable ABI](#) (including all members).*

Describes a field of a struct sequence. As a struct sequence is modeled as a tuple, all fields are typed as `PyObject*`. The index in the `fields` array of the `PyStructSequence_Desc` determines which field of the struct sequence is described.

`const char *name`

Name for the field or `NULL` to end the list of named fields, set to `PyStructSequence_UnnamedField` to leave unnamed.

`const char *doc`

Field docstring or `NULL` to omit.

`const char *const PyStructSequence_UnnamedField`

*Part of the [Stable ABI](#) since version 3.11.*

Special value for a field name to leave it unnamed.

*Changed in version 3.9:* The type was changed from `char *`.

`PyObject *PyStructSequence_New(PyObject *type)`

*Return value: New reference. Part of the [Stable ABI](#).*

Creates an instance of `type`, which must have been created with `PyStructSequence_NewType()`.

`PyObject *PyStructSequence_GetItem(PyObject *p, Py_ssize_t pos)`

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Return the object at position `pos` in the struct sequence pointed to by `p`. No bounds checking is performed.

`PyObject *PyStructSequence_GET_ITEM(PyObject *p, Py_ssize_t pos)`

*Return value: Borrowed reference.*

Macro equivalent of `PyStructSequence_GetItem()`.

`void PyStructSequence_SetItem(PyObject *p, Py_ssize_t pos, PyObject *o)`

*Part of the [Stable ABI](#).*

Sets the field at index *pos* of the struct sequence *p* to value *o*. Like `PyTuple_SET_ITEM()`, this should only be used to fill in brand new instances.

### **Note**

This function “steals” a reference to *o*.

```
void PyStructSequence_SET_ITEM(PyObject *p, Py_ssize_t *pos,  
PyObject *o)
```

Similar to `PyStructSequence_SetItem()`, but implemented as a static inlined function.

### **Note**

This function “steals” a reference to *o*.

# List Objects

type PyObject

This subtype of `PyObject` represents a Python list object.

`PyTypeObject` `PyList_Type`

*Part of the [Stable ABI](#).*

This instance of `PyTypeObject` represents the Python list type. This is the same object as `list` in the Python layer.

int `PyList_Check(PyObject *p)`

Return true if `p` is a list object or an instance of a subtype of the list type. This function always succeeds.

int `PyList_CheckExact(PyObject *p)`

Return true if `p` is a list object, but not an instance of a subtype of the list type. This function always succeeds.

`PyObject *``PyList_New(Py_ssize_t len)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new list of length `len` on success, or `NULL` on failure.

## Note

If `len` is greater than zero, the returned list object's items are set to `NULL`. Thus you cannot use abstract API functions such as `PySequence_SetItem()` or expose the object to Python code before setting all items to a real object with `PyList_SetItem()`.

`Py_ssize_t` `PyList_Size(PyObject *list)`

*Part of the [Stable ABI](#).*

Return the length of the list object in *list*; this is equivalent to `len(list)` on a list object.

`Py_ssize_t PyList_GET_SIZE(PyObject *list)`

Similar to `PyList_Size()`, but without error checking.

`PyObject *PyList_GetItem(PyObject *list, Py_ssize_t index)`

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Return the object at position *index* in the list pointed to by *list*. The position must be non-negative; indexing from the end of the list is not supported. If *index* is out of bounds ( $< 0$  or  $\geq \text{len}(\text{list})$ ), return `NULL` and set an `IndexError` exception.

`PyObject *PyList_GET_ITEM(PyObject *list, Py_ssize_t i)`

*Return value: Borrowed reference.*

Similar to `PyList_GetItem()`, but without error checking.

`int PyList_SetItem(PyObject *list, Py_ssize_t index, PyObject *item)`

*Part of the [Stable ABI](#).*

Set the item at index *index* in list to *item*. Return `0` on success. If *index* is out of bounds, return `-1` and set an `IndexError` exception.

### Note

This function “steals” a reference to *item* and discards a reference to an item already in the list at the affected position.

`void PyList_SET_ITEM(PyObject *list, Py_ssize_t i, PyObject *o)`

Macro form of `PyList_SetItem()` without error checking. This is normally only used to fill in new lists where there is no previous content.

### Note

This macro “steals” a reference to *item*, and, unlike `PyList_SetItem()`, does *not* discard a reference to any item that is being replaced; any reference in *list* at position *i* will be leaked.

`int PyList_Insert(PyObject *list, Py_ssize_t index, PyObject *item)`

*Part of the [Stable ABI](#).*

Insert the item *item* into list *list* in front of index *index*. Return 0 if successful; return -1 and set an exception if unsuccessful. Analogous to `list.insert(index, item)`.

`int PyList_Append(PyObject *list, PyObject *item)`

*Part of the [Stable ABI](#).*

Append the object *item* at the end of list *list*. Return 0 if successful; return -1 and set an exception if unsuccessful. Analogous to `list.append(item)`.

`PyObject *PyList_GetSlice(PyObject *list, Py_ssize_t low, Py_ssize_t high)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a list of the objects in *list* containing the objects *between low and high*. Return NULL and set an exception if unsuccessful. Analogous to `list[low:high]`. Indexing from the end of the list is not supported.

`int PyList_SetSlice(PyObject *list, Py_ssize_t low, Py_ssize_t high, PyObject *itemlist)`

*Part of the [Stable ABI](#).*

Set the slice of *list* between *low* and *high* to the contents of *itemlist*. Analogous to `list[low:high] = itemlist`. The *itemlist* may be NULL, indicating the assignment of an empty list (slice deletion). Return 0 on success, -1 on failure. Indexing from the end of the list is not supported.

`int PyList_Sort(PyObject *list)`

*Part of the [Stable ABI](#).*

Sort the items of *list* in place. Return 0 on success, -1 on failure. This is equivalent to `list.sort()`.

`int PyList_Reverse(PyObject *list)`

*Part of the [Stable ABI](#).*

Reverse the items of *list* in place. Return 0 on success, -1 on failure. This is the equivalent of `list.reverse()`.

`PyObject *PyList_AsTuple(PyObject *list)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new tuple object containing the contents of *list*; equivalent to `tuple(list)`.

# Dictionary Objects

type PyDictObject

This subtype of **PyObject** represents a Python dictionary object.

**PyTypeObject** PyDict\_Type

*Part of the [Stable ABI](#).*

This instance of **PyTypeObject** represents the Python dictionary type. This is the same object as **dict** in the Python layer.

int PyDict\_Check(**PyObject** \*p)

Return true if *p* is a dict object or an instance of a subtype of the dict type. This function always succeeds.

int PyDict\_CheckExact(**PyObject** \*p)

Return true if *p* is a dict object, but not an instance of a subtype of the dict type. This function always succeeds.

**PyObject** \*PyDict\_New()

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new empty dictionary, or `NULL` on failure.

**PyObject** \*PyDictProxy\_New(**PyObject** \*mapping)

*Return value: New reference. Part of the [Stable ABI](#).*

Return a **types.MappingProxyType** object for a mapping which enforces read-only behavior. This is normally used to create a view to prevent modification of the dictionary for non-dynamic class types.

void PyDict\_Clear(**PyObject** \*p)

Part of the *Stable ABI*.

Empty an existing dictionary of all key-value pairs.

`int PyDict_Contains(PyObject *p, PyObject *key)`

Part of the *Stable ABI*.

Determine if dictionary *p* contains *key*. If an item in *p* matches *key*, return 1, otherwise return 0. On error, return -1. This is equivalent to the Python expression `key in p`.

`PyObject *PyDict_Copy(PyObject *p)`

Return value: New reference. Part of the *Stable ABI*.

Return a new dictionary that contains the same key-value pairs as *p*.

`int PyDict_SetItem(PyObject *p, PyObject *key, PyObject *val)`

Part of the *Stable ABI*.

Insert *val* into the dictionary *p* with a key of *key*. *key* must be *hashable*; if it isn't, **TypeError** will be raised. Return 0 on success or -1 on failure. This function *does not* steal a reference to *val*.

`int PyDict_SetItemString(PyObject *p, const char *key, PyObject *val)`

Part of the *Stable ABI*.

This is the same as `PyDict_SetItem()`, but *key* is specified as a `const char*` UTF-8 encoded bytes string, rather than a `PyObject*`.

`int PyDict_DelItem(PyObject *p, PyObject *key)`

Part of the *Stable ABI*.

Remove the entry in dictionary *p* with key *key*. *key* must be *hashable*; if it isn't, **TypeError** is raised. If *key* is not in the dictionary, **KeyError** is raised. Return 0 on success or -1 on failure.

`int PyDict_DelItemString(PyObject *p, const char *key)`

Part of the *Stable ABI*.

This is the same as `PyDict_DelItem()`, but `key` is specified as a `const char*` UTF-8 encoded bytes string, rather than a `PyObject*`.

`PyObject *PyDict_GetItem(PyObject *p, PyObject *key)`

*Return value:* Borrowed reference. Part of the *Stable ABI*.

Return the object from dictionary `p` which has a key `key`.

Return `NULL` if the key `key` is not present, but *without* setting an exception.

### Note

Exceptions that occur while this calls `__hash__()` and `__eq__()` methods are silently ignored. Prefer the `PyDict_GetItemWithError()` function instead.

*Changed in version 3.10:* Calling this API without *GIL* held had been allowed for historical reason. It is no longer allowed.

`PyObject *PyDict_GetItemWithError(PyObject *p, PyObject *key)`

*Return value:* Borrowed reference. Part of the *Stable ABI*.

Variant of `PyDict_GetItem()` that does not suppress exceptions. Return `NULL` **with** an exception set if an exception occurred. Return `NULL` **without** an exception set if the key wasn't present.

`PyObject *PyDict_GetItemString(PyObject *p, const char *key)`

*Return value:* Borrowed reference. Part of the *Stable ABI*.

This is the same as `PyDict_GetItem()`, but `key` is specified as a `const char*` UTF-8 encoded bytes string, rather than a `PyObject*`.

### Note

Exceptions that occur while this calls `__hash__()` and `__eq__()` methods or while creating the temporary `str` object are silently ignored. Prefer using the

`PyDict_GetItemWithError()` function with your own `PyUnicode_FromString()` key instead.

`PyObject *PyDict_SetDefault(PyObject *p, PyObject *key, PyObject *defaultobj)`

*Return value: Borrowed reference.*

This is the same as the Python-level `dict.setdefault()`.

If present, it returns the value corresponding to *key* from the dictionary *p*. If the key is not in the dict, it is inserted with value *defaultobj* and *defaultobj* is returned. This function evaluates the hash function of *key* only once, instead of evaluating it independently for the lookup and the insertion.

*New in version 3.4.*

`PyObject *PyDict_Items(PyObject *p)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a `PyListObject` containing all the items from the dictionary.

`PyObject *PyDict_Keys(PyObject *p)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a `PyListObject` containing all the keys from the dictionary.

`PyObject *PyDict_Values(PyObject *p)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a `PyListObject` containing all the values from the dictionary *p*.

`Py_ssize_t PyDict_Size(PyObject *p)`

*Part of the [Stable ABI](#).*

Return the number of items in the dictionary. This is equivalent to `len(p)` on a dictionary.

```
int PyDict_Next(PyObject *p, Py_ssize_t *ppos, PyObject **pkey,
PyObject **pvalue)
```

*Part of the [Stable ABI](#).*

Iterate over all key-value pairs in the dictionary *p*. The `Py_ssize_t` referred to by *ppos* must be initialized to 0 prior to the first call to this function to start the iteration; the function returns true for each pair in the dictionary, and false once all pairs have been reported. The parameters *pkey* and *pvalue* should either point to `PyObject*` variables that will be filled in with each key and value, respectively, or may be NULL. Any references returned through them are borrowed. *ppos* should not be altered during iteration. Its value represents offsets within the internal dictionary structure, and since the structure is sparse, the offsets are not consecutive.

For example:

```
PyObject *key, *value;
Py_ssize_t pos = 0;

while (PyDict_Next(self->dict, &pos, &key, &value))
    /* do something interesting with the values...
    ...
}
```

The dictionary *p* should not be mutated during iteration. It is safe to modify the values of the keys as you iterate over the dictionary, but only so long as the set of keys does not change. For example:

```
PyObject *key, *value;
Py_ssize_t pos = 0;

while (PyDict_Next(self->dict, &pos, &key, &value))
    long i = PyLong_AsLong(value);
    if (i == -1 && PyErr_Occurred()) {
        return -1;
    }
    PyObject *o = PyLong_FromLong(i + 1);
```

```

        if (o == NULL)
            return -1;
        if (PyDict_SetItem(self->dict, key, o) < 0) {
            Py_DECREF(o);
            return -1;
        }
        Py_DECREF(o);
    }
}

```

`int PyDict_Merge(PyObject *a, PyObject *b, int override)`

*Part of the [Stable ABI](#).*

Iterate over mapping object *b* adding key-value pairs to dictionary *a*. *b* may be a dictionary, or any object supporting [PyMapping\\_Keys\(\)](#) and [PyObject\\_GetItem\(\)](#). If *override* is true, existing pairs in *a* will be replaced if a matching key is found in *b*, otherwise pairs will only be added if there is not a matching key in *a*. Return 0 on success or -1 if an exception was raised.

`int PyDict_Update(PyObject *a, PyObject *b)`

*Part of the [Stable ABI](#).*

This is the same as `PyDict_Merge(a, b, 1)` in C, and is similar to `a.update(b)` in Python except that [PyDict\\_Update\(\)](#) doesn't fall back to the iterating over a sequence of key value pairs if the second argument has no "keys" attribute. Return 0 on success or -1 if an exception was raised.

`int PyDict_MergeFromSeq2(PyObject *a, PyObject *seq2, int override)`

*Part of the [Stable ABI](#).*

Update or merge into dictionary *a*, from the key-value pairs in *seq2*. *seq2* must be an iterable object producing iterable objects of length 2, viewed as key-value pairs. In case of duplicate keys, the last wins if *override* is true, else the first wins. Return 0 on success or -1 if an exception was raised. Equivalent Python (except for the return value):

```
def PyDict_MergeFromSeq2(a, seq2, override):
    for key, value in seq2:
        if override or key not in a:
            a[key] = value
```

`int PyDict_AddWatcher(PyDict_WatchCallback callback)`

Register *callback* as a dictionary watcher. Return a non-negative integer id which must be passed to future calls to `PyDict_Watch()`. In case of error (e.g. no more watcher IDs available), return `-1` and set an exception.

*New in version 3.12.*

`int PyDict_ClearWatcher(int watcher_id)`

Clear watcher identified by *watcher\_id* previously returned from `PyDict_AddWatcher()`. Return `0` on success, `-1` on error (e.g. if the given *watcher\_id* was never registered.)

*New in version 3.12.*

`int PyDict_Watch(int watcher_id, PyObject *dict)`

Mark dictionary *dict* as watched. The callback granted *watcher\_id* by `PyDict_AddWatcher()` will be called when *dict* is modified or deallocated. Return `0` on success or `-1` on error.

*New in version 3.12.*

`int PyDict_Unwatch(int watcher_id, PyObject *dict)`

Mark dictionary *dict* as no longer watched. The callback granted *watcher\_id* by `PyDict_AddWatcher()` will no longer be called when *dict* is modified or deallocated. The dict must previously have been watched by this watcher. Return `0` on success or `-1` on error.

*New in version 3.12.*

`type PyDict_WatchEvent`

Enumeration of possible dictionary watcher events:

`PyDict_EVENT_ADDED`, `PyDict_EVENT_MODIFIED`,  
`PyDict_EVENT_DELETED`, `PyDict_EVENT_CLONED`,  
`PyDict_EVENT_CLEARED`, or  
`PyDict_EVENT_DEALLOCATED`.

*New in version 3.12.*

```
typedef int (*PyDict_WatchCallback)(PyDict_WatchEvent event,  
PyObject *dict, PyObject *key, PyObject *new_value)
```

Type of a dict watcher callback function.

If *event* is `PyDict_EVENT_CLEARED` or `PyDict_EVENT_DEALLOCATED`, both *key* and *new\_value* will be `NULL`. If *event* is `PyDict_EVENT_ADDED` or `PyDict_EVENT_MODIFIED`, *new\_value* will be the new value for *key*. If *event* is `PyDict_EVENT_DELETED`, *key* is being deleted from the dictionary and *new\_value* will be `NULL`.

`PyDict_EVENT_CLONED` occurs when *dict* was previously empty and another dict is merged into it. To maintain efficiency of this operation, per-key `PyDict_EVENT_ADDED` events are not issued in this case; instead a single `PyDict_EVENT_CLONED` is issued, and *key* will be the source dictionary.

The callback may inspect but must not modify *dict*; doing so could have unpredictable effects, including infinite recursion. Do not trigger Python code execution in the callback, as it could modify the dict as a side effect.

If *event* is `PyDict_EVENT_DEALLOCATED`, taking a new reference in the callback to the about-to-be-destroyed dictionary will resurrect it and prevent it from being freed at this time. When the resurrected object is destroyed later, any watcher callbacks active at that time will be called again.

Callbacks occur before the notified modification to *dict* takes place, so the prior state of *dict* can be inspected.

If the callback sets an exception, it must return `-1`; this

exception will be printed as an unraisable exception using `PyErr_WriteUnraisable()`. Otherwise it should return 0.

There may already be a pending exception set on entry to the callback. In this case, the callback should return 0 with the same exception still set. This means the callback may not call any other API that can set an exception unless it saves and clears the exception state first, and restores it before returning.

*New in version 3.12.*

# Set Objects

This section details the public API for `set` and `frozenset` objects. Any functionality not listed below is best accessed using either the abstract object protocol (including `PyObject_CallMethod()`, `PyObject_RichCompareBool()`, `PyObject_Hash()`, `PyObject_Repr()`, `PyObject_IsTrue()`, `PyObject_Print()`, and `PyObject_GetIter()`) or the abstract number protocol (including `PyNumber_And()`, `PyNumber_Subtract()`, `PyNumber_Or()`, `PyNumber_Xor()`, `PyNumber_InPlaceAnd()`, `PyNumber_InPlaceSubtract()`, `PyNumber_InPlaceOr()`, and `PyNumber_InPlaceXor()`).

type `PySetObject`

This subtype of `PyObject` is used to hold the internal data for both `set` and `frozenset` objects. It is like a `PyDictObject` in that it is a fixed size for small sets (much like tuple storage) and will point to a separate, variable sized block of memory for medium and large sized sets (much like list storage). None of the fields of this structure should be considered public and all are subject to change. All access should be done through the documented API rather than by manipulating the values in the structure.

`PyTypeObject` `PySet_Type`

*Part of the [Stable ABI](#).*

This is an instance of `PyTypeObject` representing the Python `set` type.

`PyTypeObject` `PyFrozenSet_Type`

*Part of the [Stable ABI](#).*

This is an instance of `PyTypeObject` representing the Python `frozenset` type.

The following type check macros work on pointers to any Python

object. Likewise, the constructor functions work with any iterable Python object.

`int PySet_Check(PyObject *p)`

Return true if *p* is a **set** object or an instance of a subtype. This function always succeeds.

`int PyFrozenSet_Check(PyObject *p)`

Return true if *p* is a **frozenset** object or an instance of a subtype. This function always succeeds.

`int PyAnySet_Check(PyObject *p)`

Return true if *p* is a **set** object, a **frozenset** object, or an instance of a subtype. This function always succeeds.

`int PySet_CheckExact(PyObject *p)`

Return true if *p* is a **set** object but not an instance of a subtype. This function always succeeds.

*New in version 3.10.*

`int PyAnySet_CheckExact(PyObject *p)`

Return true if *p* is a **set** object or a **frozenset** object but not an instance of a subtype. This function always succeeds.

`int PyFrozenSet_CheckExact(PyObject *p)`

Return true if *p* is a **frozenset** object but not an instance of a subtype. This function always succeeds.

`PyObject *PySet_New(PyObject *iterable)`

*Return value:* New reference. Part of the [Stable ABI](#).

Return a new **set** containing objects returned by the *iterable*. The *iterable* may be `NULL` to create a new empty set. Return the new set on success or `NULL` on failure. Raise **TypeError** if *iterable* is not actually iterable. The constructor is also useful for copying a set (`c=set(s)`).

**PyObject** \*PyFrozenSet\_New(**PyObject** \*iterable)

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new **frozenset** containing objects returned by the *iterable*. The *iterable* may be `NULL` to create a new empty frozenset. Return the new set on success or `NULL` on failure. Raise **TypeError** if *iterable* is not actually iterable.

The following functions and macros are available for instances of **set** or **frozenset** or instances of their subtypes.

**Py\_ssize\_t** PySet\_Size(**PyObject** \*anyset)

*Part of the [Stable ABI](#).*

Return the length of a **set** or **frozenset** object.

Equivalent to `len(anyset)`. Raises a **SystemError** if *anyset* is not a **set**, **frozenset**, or an instance of a subtype.

**Py\_ssize\_t** PySet\_GET\_SIZE(**PyObject** \*anyset)

Macro form of **PySet\_Size()** without error checking.

**int** PySet\_Contains(**PyObject** \*anyset, **PyObject** \*key)

*Part of the [Stable ABI](#).*

Return `1` if found, `0` if not found, and `-1` if an error is encountered. Unlike the Python `__contains__()` method, this function does not automatically convert unhashable sets into temporary frozensets. Raise a **TypeError** if the *key* is unhashable. Raise **SystemError** if *anyset* is not a **set**, **frozenset**, or an instance of a subtype.

**int** PySet\_Add(**PyObject** \*set, **PyObject** \*key)

*Part of the [Stable ABI](#).*

Add *key* to a **set** instance. Also works with **frozenset** instances (like **PyTuple\_SetItem()** it can be used to fill in the values of brand new frozensets before they are exposed to other code). Return `0` on success or `-1` on failure. Raise a **TypeError** if the *key* is unhashable. Raise a **MemoryError** if there is no room to grow. Raise a **SystemError** if *set* is

not an instance of **set** or its subtype.

The following functions are available for instances of **set** or its subtypes but not for instances of **frozenset** or its subtypes.

`int PySet_Discard(PyObject *set, PyObject *key)`

*Part of the **Stable ABI**.*

Return 1 if found and removed, 0 if not found (no action taken), and -1 if an error is encountered. Does not raise **KeyError** for missing keys. Raise a **TypeError** if the *key* is unhashable. Unlike the Python **discard()** method, this function does not automatically convert unhashable sets into temporary frozensets. Raise **SystemError** if *set* is not an instance of **set** or its subtype.

`PyObject *PySet_Pop(PyObject *set)`

*Return value: New reference. Part of the **Stable ABI**.*

Return a new reference to an arbitrary object in the *set*, and removes the object from the *set*. Return NULL on failure.

Raise **KeyError** if the set is empty. Raise a **SystemError** if *set* is not an instance of **set** or its subtype.

`int PySet_Clear(PyObject *set)`

*Part of the **Stable ABI**.*

Empty an existing set of all elements.

# Function Objects

There are a few functions specific to Python functions.

type PyObjectFunctionObject

The C structure used for functions.

**PyObject** PyFunction\_Type

This is an instance of **PyObject** and represents the Python function type. It is exposed to Python programmers as `types.FunctionType`.

int PyFunction\_Check(**PyObject** \*o)

Return true if *o* is a function object (has type **PyFunction\_Type**). The parameter must not be `NULL`. This function always succeeds.

**PyObject** \*PyFunction\_New(**PyObject** \*code, **PyObject** \*globals)

*Return value:* New reference.

Return a new function object associated with the code object *code*. *globals* must be a dictionary with the global variables accessible to the function.

The function's docstring and name are retrieved from the code object. `__module__` is retrieved from *globals*. The argument defaults, annotations and closure are set to `NULL`. `__qualname__` is set to the same value as the code object's `co_qualname` field.

**PyObject** \*PyFunction\_NewWithQualName(**PyObject** \*code,  
**PyObject** \*globals, **PyObject** \*qualname)

*Return value:* New reference.

As **PyFunction\_New()**, but also allows setting the function object's `__qualname__` attribute. *qualname* should be a

unicode object or `NULL`; if `NULL`, the `__qualname__` attribute is set to the same value as the code object's `co_qualname` field.

*New in version 3.3.*

**PyObject \***`PyFunction_GetCode(PyObject *op)`

*Return value: Borrowed reference.*

Return the code object associated with the function object *op*.

**PyObject \***`PyFunction_GetGlobals(PyObject *op)`

*Return value: Borrowed reference.*

Return the globals dictionary associated with the function object *op*.

**PyObject \***`PyFunction_GetModule(PyObject *op)`

*Return value: Borrowed reference.*

Return a [borrowed reference](#) to the `_module_` attribute of the function object *op*. It can be `NULL`.

This is normally a string containing the module name, but can be set to any other object by Python code.

**PyObject \***`PyFunction_GetDefaults(PyObject *op)`

*Return value: Borrowed reference.*

Return the argument default values of the function object *op*. This can be a tuple of arguments or `NULL`.

**int** `PyFunction_SetDefaults(PyObject *op, PyObject *defaults)`

Set the argument default values for the function object *op*. *defaults* must be `Py_None` or a tuple.

Raises [SystemError](#) and returns `-1` on failure.

**void** `PyFunction_SetVectorcall(PyFunctionObject *func, vectorcallfunc vectorcall)`

Set the vectorcall field of a given function object *func*.

Warning: extensions using this API must preserve the behavior of the unaltered (default) vectorcall function!

*New in version 3.12.*

**PyObject \***PyFunction\_GetClosure(**PyObject \***op)

*Return value: Borrowed reference.*

Return the closure associated with the function object *op*.

This can be `NULL` or a tuple of cell objects.

**int** PyFunction\_SetClosure(**PyObject \***op, **PyObject \***closure)

Set the closure associated with the function object *op*. *closure* must be `Py_None` or a tuple of cell objects.

Raises **SystemError** and returns `-1` on failure.

**PyObject \***PyFunction\_GetAnnotations(**PyObject \***op)

*Return value: Borrowed reference.*

Return the annotations of the function object *op*. This can be a mutable dictionary or `NULL`.

**int** PyFunction\_SetAnnotations(**PyObject \***op, **PyObject \***annotations)

Set the annotations for the function object *op*. *annotations* must be a dictionary or `Py_None`.

Raises **SystemError** and returns `-1` on failure.

**int** PyFunction\_AddWatcher(**PyFunction\_WatchCallback** callback)

Register *callback* as a function watcher for the current interpreter. Return an ID which may be passed to **PyFunction\_ClearWatcher()**. In case of error (e.g. no more watcher IDs available), return `-1` and set an exception.

*New in version 3.12.*

**int** PyFunction\_ClearWatcher(**int** watcher\_id)

Clear watcher identified by *watcher\_id* previously returned from `PyFunction_AddWatcher()` for the current interpreter. Return 0 on success, or -1 and set an exception on error (e.g. if the given *watcher\_id* was never registered.)

*New in version 3.12.*

type `PyFunction_WatchEvent`

Enumeration of possible function watcher events: -

`PyFunction_EVENT_CREATE` -

`PyFunction_EVENT_DESTROY` -

`PyFunction_EVENT_MODIFY_CODE` -

`PyFunction_EVENT_MODIFY_DEFAULTS` -

`PyFunction_EVENT_MODIFY_KWDEFAULTS`

*New in version 3.12.*

typedef int (\*PyFunction\_WatchCallback)(`PyFunction_WatchEvent` event, `PyFunctionObject` \*func, `PyObject` \*new\_value)

Type of a function watcher callback function.

If *event* is `PyFunction_EVENT_CREATE` or `PyFunction_EVENT_DESTROY` then *new\_value* will be NULL. Otherwise, *new\_value* will hold a [borrowed reference](#) to the new value that is about to be stored in *func* for the attribute that is being modified.

The callback may inspect but must not modify *func*; doing so could have unpredictable effects, including infinite recursion.

If *event* is `PyFunction_EVENT_CREATE`, then the callback is invoked after *func* has been fully initialized. Otherwise, the callback is invoked before the modification to *func* takes place, so the prior state of *func* can be inspected. The runtime is permitted to optimize away the creation of function objects when possible. In such cases no event will be emitted. Although this creates the possibility of an observable difference of runtime behavior depending on optimization decisions, it does not change the semantics of the Python code being executed.

If *event* is `PyFunction_EVENT_DESTROY`, Taking a reference in the callback to the about-to-be-destroyed function will resurrect it, preventing it from being freed at this time. When the resurrected object is destroyed later, any watcher callbacks active at that time will be called again.

If the callback sets an exception, it must return `-1`; this exception will be printed as an unraisable exception using `PyErr_WriteUnraisable()`. Otherwise it should return `0`.

There may already be a pending exception set on entry to the callback. In this case, the callback should return `0` with the same exception still set. This means the callback may not call any other API that can set an exception unless it saves and clears the exception state first, and restores it before returning.

*New in version 3.12.*

# Instance Method Objects

An instance method is a wrapper for a `PyCFunction` and the new way to bind a `PyCFunction` to a class object. It replaces the former call `PyMethod_New(func, NULL, class)`.

`PyTypeObject` `PyInstanceMethod_Type`

This instance of `PyTypeObject` represents the Python instance method type. It is not exposed to Python programs.

`int` `PyInstanceMethod_Check(PyObject *o)`

Return true if `o` is an instance method object (has type `PyInstanceMethod_Type`). The parameter must not be `NULL`. This function always succeeds.

`PyObject *``PyInstanceMethod_New(PyObject *func)`

*Return value:* New reference.

Return a new instance method object, with `func` being any callable object. `func` is the function that will be called when the instance method is called.

`PyObject *``PyInstanceMethod_Function(PyObject *im)`

*Return value:* Borrowed reference.

Return the function object associated with the instance method `im`.

`PyObject *``PyInstanceMethod_GET_FUNCTION(PyObject *im)`

*Return value:* Borrowed reference.

Macro version of `PyInstanceMethod_Function()` which avoids error checking.

# Method Objects

Methods are bound function objects. Methods are always bound to an instance of a user-defined class. Unbound methods (methods bound to a class object) are no longer available.

**PyObject** PyMethod\_Type

This instance of **PyObject** represents the Python method type. This is exposed to Python programs as `types.MethodType`.

`int PyMethod_Check(PyObject *o)`

Return true if *o* is a method object (has type **PyMethod\_Type**). The parameter must not be `NULL`. This function always succeeds.

**PyObject** \*PyMethod\_New(PyObject \*func, PyObject \*self)

*Return value:* New reference.

Return a new method object, with *func* being any callable object and *self* the instance the method should be bound. *func* is the function that will be called when the method is called. *self* must not be `NULL`.

**PyObject** \*PyMethod\_Function(PyObject \*meth)

*Return value:* Borrowed reference.

Return the function object associated with the method *meth*.

**PyObject** \*PyMethod\_GET\_FUNCTION(PyObject \*meth)

*Return value:* Borrowed reference.

Macro version of **PyMethod\_Function()** which avoids error checking.

**PyObject** \*PyMethod\_Self(PyObject \*meth)

*Return value:* Borrowed reference.

Return the instance associated with the method *meth*.

`PyObject *PyMethod_GET_SELF(PyObject *meth)`

*Return value: Borrowed reference.*

Macro version of `PyMethod_Self()` which avoids error checking.

# Cell Objects

“Cell” objects are used to implement variables referenced by multiple scopes. For each such variable, a cell object is created to store the value; the local variables of each stack frame that references the value contains a reference to the cells from outer scopes which also use that variable. When the value is accessed, the value contained in the cell is used instead of the cell object itself. This de-referencing of the cell object requires support from the generated byte-code; these are not automatically de-referenced when accessed. Cell objects are not likely to be useful elsewhere.

type PyCellObject

The C structure used for cell objects.

PyTypeObject PyCell\_Type

The type object corresponding to cell objects.

int PyCell\_Check(PyObject \*ob)

Return true if *ob* is a cell object; *ob* must not be NULL. This function always succeeds.

PyObject \*PyCell\_New(PyObject \*ob)

*Return value:* New reference.

Create and return a new cell object containing the value *ob*. The parameter may be NULL.

PyObject \*PyCell\_Get(PyObject \*cell)

*Return value:* New reference.

Return the contents of the cell *cell*.

PyObject \*PyCell\_GET(PyObject \*cell)

*Return value:* Borrowed reference.

Return the contents of the cell *cell*, but without checking that *cell* is non-NULL and a cell object.

int PyCell\_Set(PyObject \*cell, PyObject \*value)

Set the contents of the cell object *cell* to *value*. This releases the reference to any current content of the cell. *value* may be NULL. *cell* must be non-NULL; if it is not a cell object, -1 will be returned. On success, 0 will be returned.

void PyCell\_SET(PyObject \*cell, PyObject \*value)

Sets the value of the cell object *cell* to *value*. No reference counts are adjusted, and no checks are made for safety; *cell* must be non-NULL and must be a cell object.

# Code Objects

Code objects are a low-level detail of the CPython implementation. Each one represents a chunk of executable code that hasn't yet been bound into a function.

type `PyCodeObject`

The C structure of the objects used to describe code objects. The fields of this type are subject to change at any time.

`PyTypeObject` `PyCode_Type`

This is an instance of `PyTypeObject` representing the Python `code` type.

int `PyCode_Check(PyObject *co)`

Return true if `co` is a `code` object. This function always succeeds.

int `PyCode_GetNumFree(PyCodeObject *co)`

Return the number of free variables in `co`.

`PyCodeObject *PyUnstable_Code_New(int argcount, int kwnonly, argcount, int nlocals, int stacksize, int flags, PyObject *code, PyObject *consts, PyObject *names, PyObject *varnames, PyObject *freevars, PyObject *cellvars, PyObject *filename, PyObject *name, PyObject *qualname, int firstlineno, PyObject *linetable, PyObject *exceptiontable)`

*This is **Unstable API**. It may change without warning in minor releases.*

Return a new code object. If you need a dummy code object to create a frame, use `PyCode_NewEmpty()` instead.

Since the definition of the bytecode changes often, calling `PyUnstable_Code_New()` directly can bind you to a precise Python version.

The many arguments of this function are inter-dependent in complex ways, meaning that subtle changes to values are likely to result in incorrect execution or VM crashes. Use this function only with extreme care.

*Changed in version 3.11:* Added `qualname` and `exceptiontable` parameters.

*Changed in version 3.12:* Renamed from `PyCode_New` as part of [Unstable C API](#). The old name is deprecated, but will remain available until the signature changes again.

```
PyObject *PyUnstable_Code_NewWithPosOnlyArgs(int
argcount, int posonlyargcount, int kwnonlyargcount, int nlocals, int
stacksize, int flags, PyObject *code, PyObject *consts, PyObject
*names, PyObject *varnames, PyObject *freevars, PyObject
*cellvars, PyObject *filename, PyObject *name, PyObject
*qualname, int firstlineno, PyObject *linetable, PyObject
*exceptiontable)
```

*This is [Unstable API](#). It may change without warning in minor releases.*

Similar to `PyUnstable_Code_New()`, but with an extra “posonlyargcount” for positional-only arguments. The same caveats that apply to `PyUnstable_Code_New` also apply to this function.

*New in version 3.8:* as `PyCode_NewWithPosOnlyArgs`

*Changed in version 3.11:* Added `qualname` and `exceptiontable` parameters.

*Changed in version 3.12:* Renamed to `PyUnstable_Code_NewWithPosOnlyArgs`. The old name is deprecated, but will remain available until the signature

changes again.

**PyObject** \*PyCode\_NewEmpty(const char \*filename, const char \*funcname, int firstlineno)

*Return value:* New reference.

Return a new empty code object with the specified filename, function name, and first line number. The resulting code object will raise an `Exception` if executed.

int PyCode\_Addr2Line(**PyObject** \*co, int byte\_offset)

Return the line number of the instruction that occurs on or before `byte_offset` and ends after it. If you just need the line number of a frame, use `PyFrame_GetLineNumber()` instead.

For efficiently iterating over the line numbers in a code object, use [the API described in PEP 626](https://peps.python.org/pep-0626/#out-of-process-debuggers-and-profilers) [https://peps.python.org/pep-0626/#out-of-process-debuggers-and-profilers].

int PyCode\_Addr2Location(**PyObject** \*co, int byte\_offset, int \*start\_line, int \*start\_column, int \*end\_line, int \*end\_column)

Sets the passed `int` pointers to the source code line and column numbers for the instruction at `byte_offset`. Sets the value to 0 when information is not available for any particular element.

Returns 1 if the function succeeds and 0 otherwise.

*New in version 3.11.*

**PyObject** \*PyCode\_GetCode(**PyObject** \*co)

Equivalent to the Python code `getattr(co, 'co_code')`. Returns a strong reference to a **PyBytesObject** representing the bytecode in a code object. On error, `NULL` is returned and an exception is raised.

This **PyBytesObject** may be created on-demand by the interpreter and does not necessarily represent the bytecode

actually executed by CPython. The primary use case for this function is debuggers and profilers.

*New in version 3.11.*

**PyObject \***PyCode\_GetVarnames(**PyCodeObject \***co)

Equivalent to the Python code `getattr(co, 'co_varnames')`. Returns a new reference to a **PyTupleObject** containing the names of the local variables. On error, `NULL` is returned and an exception is raised.

*New in version 3.11.*

**PyObject \***PyCode\_GetCellvars(**PyCodeObject \***co)

Equivalent to the Python code `getattr(co, 'co_cellvars')`. Returns a new reference to a **PyTupleObject** containing the names of the local variables that are referenced by nested functions. On error, `NULL` is returned and an exception is raised.

*New in version 3.11.*

**PyObject \***PyCode\_GetFreevars(**PyCodeObject \***co)

Equivalent to the Python code `getattr(co, 'co_freevars')`. Returns a new reference to a **PyTupleObject** containing the names of the free variables. On error, `NULL` is returned and an exception is raised.

*New in version 3.11.*

**int** PyCode\_AddWatcher(**PyCode\_WatchCallback** callback)

Register *callback* as a code object watcher for the current interpreter. Return an ID which may be passed to **PyCode\_ClearWatcher()**. In case of error (e.g. no more watcher IDs available), return `-1` and set an exception.

*New in version 3.12.*

`int PyCode_ClearWatcher(int watcher_id)`

Clear watcher identified by *watcher\_id* previously returned from `PyCode_AddWatcher()` for the current interpreter. Return 0 on success, or -1 and set an exception on error (e.g. if the given *watcher\_id* was never registered.)

*New in version 3.12.*

`type PyCodeEvent`

Enumeration of possible code object watcher events: -

`PY_CODE_EVENT_CREATE` - `PY_CODE_EVENT_DESTROY`

*New in version 3.12.*

`typedef int (*PyCode_WatchCallback)(PyCodeEvent event, PyCodeObject *co)`

Type of a code object watcher callback function.

If *event* is `PY_CODE_EVENT_CREATE`, then the callback is invoked after *co* has been fully initialized. Otherwise, the callback is invoked before the destruction of *co* takes place, so the prior state of *co* can be inspected.

If *event* is `PY_CODE_EVENT_DESTROY`, taking a reference in the callback to the about-to-be-destroyed code object will resurrect it and prevent it from being freed at this time. When the resurrected object is destroyed later, any watcher callbacks active at that time will be called again.

Users of this API should not rely on internal runtime implementation details. Such details may include, but are not limited to, the exact order and timing of creation and destruction of code objects. While changes in these details may result in differences observable by watchers (including whether a callback is invoked or not), it does not change the semantics of the Python code being executed.

If the callback sets an exception, it must return -1; this exception will be printed as an unraisable exception using `PyErr_WriteUnraisable()`. Otherwise it should return 0.

There may already be a pending exception set on entry to the callback. In this case, the callback should return 0 with the same exception still set. This means the callback may not call any other API that can set an exception unless it saves and clears the exception state first, and restores it before returning.

*New in version 3.12.*

## Extra information

To support low-level extensions to frame evaluation, such as external just-in-time compilers, it is possible to attach arbitrary extra data to code objects.

These functions are part of the unstable C API tier: this functionality is a CPython implementation detail, and the API may change without deprecation warnings.

`Py_ssize_t` `PyUnstable_Eval_RequestCodeExtraIndex(freefunc free)`

*This is [Unstable API](#). It may change without warning in minor releases.*

Return a new an opaque index value used to adding data to code objects.

You generally call this function once (per interpreter) and use the result with `PyCode_GetExtra` and `PyCode_SetExtra` to manipulate data on individual code objects.

If *free* is not `NULL`: when a code object is deallocated, *free* will be called on non-`NULL` data stored under the new index. Use [Py\\_DecRef\(\)](#) when storing [PyObject](#).

*New in version 3.6:* as `_PyEval_RequestCodeExtraIndex`

*Changed in version 3.12:* Renamed to `PyUnstable_Eval_RequestCodeExtraIndex`. The old private name is deprecated, but will be available until the API changes.

```
int PyUnstable_Code_GetExtra(PyObject *code, Py_ssize_t index,  
void **extra)
```

*This is [Unstable API](#). It may change without warning in minor releases.*

Set *extra* to the extra data stored under the given index.  
Return 0 on success. Set an exception and return -1 on failure.

If no data was set under the index, set *extra* to `NULL` and return 0 without setting an exception.

*New in version 3.6:* as `_PyCode_GetExtra`

*Changed in version 3.12:* Renamed to `PyUnstable_Code_GetExtra`. The old private name is deprecated, but will be available until the API changes.

```
int PyUnstable_Code_SetExtra(PyObject *code, Py_ssize_t index, void  
*extra)
```

*This is [Unstable API](#). It may change without warning in minor releases.*

Set the extra data stored under the given index to *extra*.  
Return 0 on success. Set an exception and return -1 on failure.

*New in version 3.6:* as `_PyCode_SetExtra`

*Changed in version 3.12:* Renamed to `PyUnstable_Code_SetExtra`. The old private name is deprecated, but will be available until the API changes.

# File Objects

These APIs are a minimal emulation of the Python 2 C API for built-in file objects, which used to rely on the buffered I/O (FILE\*) support from the C standard library. In Python 3, files and streams use the new `io` module, which defines several layers over the low-level unbuffered I/O of the operating system. The functions described below are convenience C wrappers over these new APIs, and meant mostly for internal error reporting in the interpreter; third-party code is advised to access the `io` APIs instead.

**PyObject** \*PyFile\_FromFd(int fd, const char \*name, const char \*mode, int buffering, const char \*encoding, const char \*errors, const char \*newline, int closefd)

*Return value:* New reference. Part of the [Stable ABI](#).

Create a Python file object from the file descriptor of an already opened file *fd*. The arguments *name*, *encoding*, *errors* and *newline* can be `NULL` to use the defaults; *buffering* can be `-1` to use the default. *name* is ignored and kept for backward compatibility. Return `NULL` on failure. For a more comprehensive description of the arguments, please refer to the [io.open\(\)](#) function documentation.

## Warning

Since Python streams have their own buffering layer, mixing them with OS-level file descriptors can produce various issues (such as unexpected ordering of data).

*Changed in version 3.2:* Ignore *name* attribute.

int PyObject\_AsFileDescriptor(PyObject \*p)

*Part of the [Stable ABI](#).*

Return the file descriptor associated with *p* as an int. If the object is an integer, its value is returned. If not, the object's

`fileno()` method is called if it exists; the method must return an integer, which is returned as the file descriptor value. Sets an exception and returns `-1` on failure.

`PyObject *PyFile_GetLine(PyObject *p, int n)`

*Return value:* New reference. Part of the [Stable ABI](#).

Equivalent to `p.readline([n])`, this function reads one line from the object `p`. `p` may be a file object or any object with a `readline()` method. If `n` is `0`, exactly one line is read, regardless of the length of the line. If `n` is greater than `0`, no more than `n` bytes will be read from the file; a partial line can be returned. In both cases, an empty string is returned if the end of the file is reached immediately. If `n` is less than `0`, however, one line is read regardless of length, but `EOFError` is raised if the end of the file is reached immediately.

`int PyFile_SetOpenCodeHook(Py_OpenCodeHookFunction handler)`

Overrides the normal behavior of `io.open_code()` to pass its parameter through the provided handler.

The handler is a function of type `PyObject (*)(PyObject *path, void *userData)`, where `path` is guaranteed to be `PyUnicodeObject`.

The `userData` pointer is passed into the hook function. Since hook functions may be called from different runtimes, this pointer should not refer directly to Python state.

As this hook is intentionally used during import, avoid importing new modules during its execution unless they are known to be frozen or available in `sys.modules`.

Once a hook has been set, it cannot be removed or replaced, and later calls to `PyFile_SetOpenCodeHook()` will fail. On failure, the function returns `-1` and sets an exception if the interpreter has been initialized.

This function is safe to call before `Py_Initialize()`.

Raises an [auditing event](#) `setopencodehook` with no arguments.

*New in version 3.8.*

`int PyFile_WriteObject(PyObject *obj, PyObject *p, int flags)`

*Part of the [Stable ABI](#).*

Write object *obj* to file object *p*. The only supported flag for *flags* is `Py_PRINT_RAW`; if given, the `str()` of the object is written instead of the `repr()`. Return 0 on success or -1 on failure; the appropriate exception will be set.

`int PyFile_WriteString(const char *s, PyObject *p)`

*Part of the [Stable ABI](#).*

Write string *s* to file object *p*. Return 0 on success or -1 on failure; the appropriate exception will be set.

# Module Objects

**PyTypeObject** PyModule\_Type

*Part of the [Stable ABI](#).*

This instance of **PyTypeObject** represents the Python module type. This is exposed to Python programs as `types.ModuleType`.

`int PyModule_Check(PyObject *p)`

Return true if *p* is a module object, or a subtype of a module object. This function always succeeds.

`int PyModule_CheckExact(PyObject *p)`

Return true if *p* is a module object, but not a subtype of **PyModule\_Type**. This function always succeeds.

**PyObject** \*PyModule\_NewObject(PyObject \*name)

*Return value: New reference. Part of the [Stable ABI](#) since version 3.7.*

Return a new module object with the `__name__` attribute set to *name*. The module's `__name__`, `__doc__`, `__package__`, and `__loader__` attributes are filled in (all but `__name__` are set to `None`); the caller is responsible for providing a `__file__` attribute.

*New in version 3.3.*

*Changed in version 3.4:* `__package__` and `__loader__` are set to `None`.

**PyObject** \*PyModule\_New(const char \*name)

*Return value: New reference. Part of the [Stable ABI](#).*

Similar to **PyModule\_NewObject()**, but the name is a UTF-8 encoded string instead of a Unicode object.

**PyObject** \*PyModule\_GetDict(**PyObject** \*module)

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Return the dictionary object that implements *module*'s namespace; this object is the same as the `__dict__` attribute of the module object. If *module* is not a module object (or a subtype of a module object), **SystemError** is raised and `NULL` is returned.

It is recommended extensions use other `PyModule_*` and `PyObject_*` functions rather than directly manipulate a module's `__dict__`.

**PyObject** \*PyModule\_GetNameObject(**PyObject** \*module)

*Return value: New reference. Part of the [Stable ABI](#) since version 3.7.*

Return *module*'s `__name__` value. If the module does not provide one, or if it is not a string, **SystemError** is raised and `NULL` is returned.

*New in version 3.3.*

`const char` \*PyModule\_GetName(**PyObject** \*module)

*Part of the [Stable ABI](#).*

Similar to `PyModule_GetNameObject()` but return the name encoded to `'utf-8'`.

`void` \*PyModule\_GetState(**PyObject** \*module)

*Part of the [Stable ABI](#).*

Return the “state” of the module, that is, a pointer to the block of memory allocated at module creation time, or `NULL`. See `PyModuleDef.m_size`.

**PyModuleDef** \*PyModule\_GetDef(**PyObject** \*module)

*Part of the [Stable ABI](#).*

Return a pointer to the **PyModuleDef** struct from which the module was created, or `NULL` if the module wasn't created from a definition.

`PyObject *PyModule_GetFilenameObject(PyObject *module)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return the name of the file from which *module* was loaded using *module*'s `__file__` attribute. If this is not defined, or if it is not a unicode string, raise `SystemError` and return `NULL`; otherwise return a reference to a Unicode object.

*New in version 3.2.*

`const char *PyModule_GetFilename(PyObject *module)`

*Part of the [Stable ABI](#).*

Similar to `PyModule_GetFilenameObject()` but return the filename encoded to 'utf-8'.

*Deprecated since version 3.2: `PyModule_GetFilename()` raises `UnicodeEncodeError` on unencodable filenames, use `PyModule_GetFilenameObject()` instead.*

## Initializing C modules

Modules objects are usually created from extension modules (shared libraries which export an initialization function), or compiled-in modules (where the initialization function is added using `PyImport_AppendInittab()`). See [Building C and C++ Extensions](#) or [Extending Embedded Python](#) for details.

The initialization function can either pass a module definition instance to `PyModule_Create()`, and return the resulting module object, or request “multi-phase initialization” by returning the definition struct itself.

`type PyModuleDef`

*Part of the [Stable ABI](#) (including all members).*

The module definition struct, which holds all information needed to create a module object. There is usually only one statically initialized variable of this type for each module.

`PyModuleDef_Base m_base`

Always initialize this member to

**PyModuleDef\_HEAD\_INIT.**

const char \*m\_name

Name for the new module.

const char \*m\_doc

Docstring for the module; usually a docstring variable created with **PyDoc\_STRVAR** is used.

**Py\_ssize\_t** m\_size

Module state may be kept in a per-module memory area that can be retrieved with **PyModule\_GetState()**, rather than in static globals. This makes modules safe for use in multiple sub-interpreters.

This memory area is allocated based on *m\_size* on module creation, and freed when the module object is deallocated, after the **m\_free** function has been called, if present.

Setting *m\_size* to -1 means that the module does not support sub-interpreters, because it has global state.

Setting it to a non-negative value means that the module can be re-initialized and specifies the additional amount of memory it requires for its state. Non-negative *m\_size* is required for multi-phase initialization.

See **PEP 3121** [<https://peps.python.org/pep-3121/>] for more details.

**PyMethodDef** \*m\_methods

A pointer to a table of module-level functions, described by **PyMethodDef** values. Can be **NULL** if no functions are present.

**PyModuleDef\_Slot** \*m\_slots

An array of slot definitions for multi-phase initialization, terminated by a `{0, NULL}` entry. When using single-phase initialization, `m_slots` must be `NULL`.

*Changed in version 3.5:* Prior to version 3.5, this member was always set to `NULL`, and was defined as:

`inquiry m_reload`

`traverseproc m_traverse`

A traversal function to call during GC traversal of the module object, or `NULL` if not needed.

This function is not called if the module state was requested but is not allocated yet. This is the case immediately after the module is created and before the module is executed (`Py_mod_exec` function). More precisely, this function is not called if `m_size` is greater than 0 and the module state (as returned by `PyModule_GetState()`) is `NULL`.

*Changed in version 3.9:* No longer called before the module state is allocated.

`inquiry m_clear`

A clear function to call during GC clearing of the module object, or `NULL` if not needed.

This function is not called if the module state was requested but is not allocated yet. This is the case immediately after the module is created and before the module is executed (`Py_mod_exec` function). More precisely, this function is not called if `m_size` is greater than 0 and the module state (as returned by `PyModule_GetState()`) is `NULL`.

Like `PyTypeObject.tp_clear`, this function is not *always* called before a module is deallocated. For example, when reference counting is enough to

determine that an object is no longer used, the cyclic garbage collector is not involved and `m_free` is called directly.

*Changed in version 3.9:* No longer called before the module state is allocated.

`freefunc m_free`

A function to call during deallocation of the module object, or `NULL` if not needed.

This function is not called if the module state was requested but is not allocated yet. This is the case immediately after the module is created and before the module is executed (`Py_mod_exec` function). More precisely, this function is not called if `m_size` is greater than 0 and the module state (as returned by `PyModule_GetState()`) is `NULL`.

*Changed in version 3.9:* No longer called before the module state is allocated.

## Single-phase initialization

The module initialization function may create and return the module object directly. This is referred to as “single-phase initialization”, and uses one of the following two module creation functions:

`PyObject *PyModule_Create(PyModuleDef *def)`

*Return value:* New reference.

Create a new module object, given the definition in *def*. This behaves like `PyModule_Create2()` with *module\_api\_version* set to `PYTHON_API_VERSION`.

`PyObject *PyModule_Create2(PyModuleDef *def, int module_api_version)`

*Return value:* New reference. Part of the [Stable ABI](#).

Create a new module object, given the definition in *def*,

assuming the API version *module\_api\_version*. If that version does not match the version of the running interpreter, a **RuntimeWarning** is emitted.

## Note

Most uses of this function should be using **PyModule\_Create()** instead; only use this if you are sure you need it.

Before it is returned from in the initialization function, the resulting module object is typically populated using functions like **PyModule\_AddObjectRef()**.

## Multi-phase initialization

An alternate way to specify extensions is to request “multi-phase initialization”. Extension modules created this way behave more like Python modules: the initialization is split between the *creation phase*, when the module object is created, and the *execution phase*, when it is populated. The distinction is similar to the **\_\_new\_\_()** and **\_\_init\_\_()** methods of classes.

Unlike modules created using single-phase initialization, these modules are not singletons: if the *sys.modules* entry is removed and the module is re-imported, a new module object is created, and the old module is subject to normal garbage collection – as with Python modules. By default, multiple modules created from the same definition should be independent: changes to one should not affect the others. This means that all state should be specific to the module object (using e.g. using **PyModule\_GetState()**), or its contents (such as the module’s **\_\_dict\_\_** or individual classes created with **PyType\_FromSpec()**).

All modules created using multi-phase initialization are expected to support **sub-interpreters**. Making sure multiple modules are independent is typically enough to achieve this.

To request multi-phase initialization, the initialization function

(PyInit\_modulename) returns a `PyModuleDef` instance with non-empty `m_slots`. Before it is returned, the `PyModuleDef` instance must be initialized with the following function:

`PyObject *PyModuleDef_Init(PyModuleDef *def)`

*Return value: Borrowed reference. Part of the [Stable ABI](#) since version 3.5.*

Ensures a module definition is a properly initialized Python object that correctly reports its type and reference count.

Returns `def` cast to `PyObject*`, or `NULL` if an error occurred.

*New in version 3.5.*

The `m_slots` member of the module definition must point to an array of `PyModuleDef_Slot` structures:

`type PyModuleDef_Slot`

`int slot`

A slot ID, chosen from the available values explained below.

`void *value`

Value of the slot, whose meaning depends on the slot ID.

*New in version 3.5.*

The `m_slots` array must be terminated by a slot with id 0.

The available slot types are:

`Py_mod_create`

Specifies a function that is called to create the module object itself. The *value* pointer of this slot must point to a function of the signature:

`PyObject *create_module(PyObject *spec, PyModuleDef *def)`

The function receives a `ModuleSpec` instance, as defined in [PEP 451](https://peps.python.org/pep-0451/) [https://peps.python.org/pep-0451/], and the module definition. It should return a new module object, or set an error and return `NULL`.

This function should be kept minimal. In particular, it should not call arbitrary Python code, as trying to import the same module again may result in an infinite loop.

Multiple `Py_mod_create` slots may not be specified in one module definition.

If `Py_mod_create` is not specified, the import machinery will create a normal module object using `PyModule_New()`. The name is taken from `spec`, not the definition, to allow extension modules to dynamically adjust to their place in the module hierarchy and be imported under different names through symlinks, all while sharing a single module definition.

There is no requirement for the returned object to be an instance of `PyModule_Type`. Any type can be used, as long as it supports setting and getting import-related attributes. However, only `PyModule_Type` instances may be returned if the `PyModuleDef` has non-NULL `m_traverse`, `m_clear`, `m_free`; non-zero `m_size`; or slots other than `Py_mod_create`.

## `Py_mod_exec`

Specifies a function that is called to *execute* the module. This is equivalent to executing the code of a Python module: typically, this function adds classes and constants to the module. The signature of the function is:

`int exec_module(PyObject *module)`

If multiple `Py_mod_exec` slots are specified, they are processed in the order they appear in the `m_slots` array.

## `Py_mod_multiple_interpreters`

Specifies one of the following values:

### `Py_MOD_MULTIPLE_INTERPRETERS_NOT_SUPPORTED`

The module does not support being imported in subinterpreters.

### `Py_MOD_MULTIPLE_INTERPRETERS_SUPPORTED`

The module supports being imported in subinterpreters, but only when they share the main interpreter's GIL. (See [Isolating Extension Modules](#).)

### `Py_MOD_PER_INTERPRETER_GIL_SUPPORTED`

The module supports being imported in subinterpreters, even when they have their own GIL. (See [Isolating Extension Modules](#).)

This slot determines whether or not importing this module in a subinterpreter will fail.

Multiple `Py_mod_multiple_interpreters` slots may not be specified in one module definition.

If `Py_mod_multiple_interpreters` is not specified, the import machinery defaults to `Py_MOD_MULTIPLE_INTERPRETERS_NOT_SUPPORTED`.

*New in version 3.12.*

See [PEP 489](#) [<https://peps.python.org/pep-0489/>] for more details on multi-phase initialization.

## Low-level module creation functions

The following functions are called under the hood when using multi-phase initialization. They can be used directly, for example when creating module objects dynamically. Note that both `PyModule_FromDefAndSpec` and `PyModule_ExecDef` must be called to fully initialize a module.

`PyObject *``PyModule_FromDefAndSpec(PyModuleDef *def,`  
`PyObject *spec)`

*Return value: New reference.*

Create a new module object, given the definition in *def* and the `ModuleSpec` *spec*. This behaves like

`PyModule_FromDefAndSpec2()` with *module\_api\_version* set to `PYTHON_API_VERSION`.

*New in version 3.5.*

`PyObject *``PyModule_FromDefAndSpec2(PyModuleDef *def,`  
`PyObject *spec, int module_api_version)`

*Return value: New reference. Part of the [Stable ABI](#) since version 3.7.*

Create a new module object, given the definition in *def* and the `ModuleSpec` *spec*, assuming the API version *module\_api\_version*. If that version does not match the version of the running interpreter, a `RuntimeWarning` is emitted.

### Note

Most uses of this function should be using `PyModule_FromDefAndSpec()` instead; only use this if you are sure you need it.

*New in version 3.5.*

`int` `PyModule_ExecDef(PyObject *module, PyModuleDef *def)`

*Part of the [Stable ABI](#) since version 3.7.*

Process any execution slots (`Py_mod_exec`) given in *def*.

*New in version 3.5.*

`int` `PyModule_SetDocString(PyObject *module, const char`  
`*docstring)`

*Part of the [Stable ABI](#) since version 3.7.*

Set the docstring for *module* to *docstring*. This function is

called automatically when creating a module from `PyModuleDef`, using either `PyModule_Create` or `PyModule_FromDefAndSpec`.

*New in version 3.5.*

```
int PyModule_AddFunctions(PyObject *module, PyMethodDef
*functions)
```

*Part of the [Stable ABI](#) since version 3.7.*

Add the functions from the `NULL` terminated *functions* array to *module*. Refer to the [PyMethodDef](#) documentation for details on individual entries (due to the lack of a shared module namespace, module level “functions” implemented in C typically receive the module as their first parameter, making them similar to instance methods on Python classes). This function is called automatically when creating a module from `PyModuleDef`, using either `PyModule_Create` or `PyModule_FromDefAndSpec`.

*New in version 3.5.*

## Support functions

The module initialization function (if using single phase initialization) or a function called from a module execution slot (if using multi-phase initialization), can use the following functions to help initialize the module state:

```
int PyModule_AddObjectRef(PyObject *module, const char *name,
PyObject *value)
```

*Part of the [Stable ABI](#) since version 3.10.*

Add an object to *module* as *name*. This is a convenience function which can be used from the module’s initialization function.

On success, return `0`. On error, raise an exception and return `-1`.

Return `NULL` if *value* is `NULL`. It must be called with an

exception raised in this case.

Example usage:

```
static int
add_spam(PyObject *module, int value)
{
    PyObject *obj = PyLong_FromLong(value);
    if (obj == NULL) {
        return -1;
    }
    int res = PyModule_AddObjectRef(module, "spam",
    Py_DECREF(obj);
    return res;
}
```

The example can also be written without checking explicitly if *obj* is `NULL`:

```
static int
add_spam(PyObject *module, int value)
{
    PyObject *obj = PyLong_FromLong(value);
    int res = PyModule_AddObjectRef(module, "spam",
    Py_XDECREF(obj);
    return res;
}
```

Note that `Py_XDECREF()` should be used instead of `Py_DECREF()` in this case, since *obj* can be `NULL`.

*New in version 3.10.*

`int PyModule_AddObject(PyObject *module, const char *name, PyObject *value)`

Part of the [Stable ABI](#).

Similar to `PyModule_AddObjectRef()`, but steals a reference to *value* on success (if it returns 0).

The new `PyModule_AddObjectRef()` function is

recommended, since it is easy to introduce reference leaks by misusing the `PyModule_AddObject()` function.

### Note

Unlike other functions that steal references, `PyModule_AddObject()` only releases the reference to *value* on success.

This means that its return value must be checked, and calling code must `Py_DECREF()` *value* manually on error.

Example usage:

```
static int
add_spam(PyObject *module, int value)
{
    PyObject *obj = PyLong_FromLong(value);
    if (obj == NULL) {
        return -1;
    }
    if (PyModule_AddObject(module, "spam", obj) < 0)
        Py_DECREF(obj);
    return -1;
}
// PyModule_AddObject() stole a reference to obj
// Py_DECREF(obj) is not needed here
return 0;
}
```

The example can also be written without checking explicitly if *obj* is `NULL`:

```
static int
add_spam(PyObject *module, int value)
{
    PyObject *obj = PyLong_FromLong(value);
    if (PyModule_AddObject(module, "spam", obj) < 0)
        Py_XDECREF(obj);
    return -1;
}
```

```

    }
    // PyModule_AddObject() stole a reference to ob
    // Py_DECREF(obj) is not needed here
    return 0;
}

```

Note that `Py_XDECREF()` should be used instead of `Py_DECREF()` in this case, since *obj* can be `NULL`.

`int PyModule_AddIntConstant(PyObject *module, const char *name, long value)`

*Part of the [Stable ABI](#).*

Add an integer constant to *module* as *name*. This convenience function can be used from the module's initialization function. Return `-1` on error, `0` on success.

`int PyModule_AddStringConstant(PyObject *module, const char *name, const char *value)`

*Part of the [Stable ABI](#).*

Add a string constant to *module* as *name*. This convenience function can be used from the module's initialization function. The string *value* must be `NULL`-terminated. Return `-1` on error, `0` on success.

`PyModule_AddIntMacro(module, macro)`

Add an int constant to *module*. The name and the value are taken from *macro*. For example

`PyModule_AddIntMacro(module, AF_INET)` adds the int constant `AF_INET` with the value of `AF_INET` to *module*. Return `-1` on error, `0` on success.

`PyModule_AddStringMacro(module, macro)`

Add a string constant to *module*.

`int PyModule_AddType(PyObject *module, PyTypeObject *type)`

*Part of the [Stable ABI](#) since version 3.10.*

Add a type object to *module*. The type object is finalized by

calling internally `PyType_Ready()`. The name of the type object is taken from the last component of `tp_name` after dot. Return `-1` on error, `0` on success.

*New in version 3.9.*

## Module lookup

Single-phase initialization creates singleton modules that can be looked up in the context of the current interpreter. This allows the module object to be retrieved later with only a reference to the module definition.

These functions will not work on modules created using multi-phase initialization, since multiple such modules can be created from a single definition.

`PyObject *``PyState_FindModule(PyModuleDef *def)`

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Returns the module object that was created from `def` for the current interpreter. This method requires that the module object has been attached to the interpreter state with `PyState_AddModule()` beforehand. In case the corresponding module object is not found or has not been attached to the interpreter state yet, it returns `NULL`.

`int` `PyState_AddModule(PyObject *module, PyModuleDef *def)`

*Part of the [Stable ABI](#) since version 3.3.*

Attaches the module object passed to the function to the interpreter state. This allows the module object to be accessible via `PyState_FindModule()`.

Only effective on modules created using single-phase initialization.

Python calls `PyState_AddModule` automatically after importing a module, so it is unnecessary (but harmless) to call it from module initialization code. An explicit call is needed only if the module's own init code subsequently calls

`PyState_FindModule`. The function is mainly intended for implementing alternative import mechanisms (either by calling it directly, or by referring to its implementation for details of the required state updates).

The caller must hold the GIL.

Return 0 on success or -1 on failure.

*New in version 3.3.*

`int PyState_RemoveModule(PyModuleDef *def)`

*Part of the [Stable ABI](#) since version 3.3.*

Removes the module object created from *def* from the interpreter state. Return 0 on success or -1 on failure.

The caller must hold the GIL.

*New in version 3.3.*

# Iterator Objects

Python provides two general-purpose iterator objects. The first, a sequence iterator, works with an arbitrary sequence supporting the `__getitem__()` method. The second works with a callable object and a sentinel value, calling the callable for each item in the sequence, and ending the iteration when the sentinel value is returned.

`PyObject PySeqIter_Type`

*Part of the [Stable ABI](#).*

Type object for iterator objects returned by `PySeqIter_New()` and the one-argument form of the `iter()` built-in function for built-in sequence types.

`int PySeqIter_Check(PyObject *op)`

Return true if the type of `op` is `PySeqIter_Type`. This function always succeeds.

`PyObject *PySeqIter_New(PyObject *seq)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return an iterator that works with a general sequence object, `seq`. The iteration ends when the sequence raises `IndexError` for the subscripting operation.

`PyObject PyCallIter_Type`

*Part of the [Stable ABI](#).*

Type object for iterator objects returned by `PyCallIter_New()` and the two-argument form of the `iter()` built-in function.

`int PyCallIter_Check(PyObject *op)`

Return true if the type of `op` is `PyCallIter_Type`. This function always succeeds.

`PyObject *PyCallIter_New(PyObject *callable, PyObject *sentinel)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new iterator. The first parameter, *callable*, can be any Python callable object that can be called with no parameters; each call to it should return the next item in the iteration. When *callable* returns a value equal to *sentinel*, the iteration will be terminated.

# Descriptor Objects

“Descriptors” are objects that describe some attribute of an object. They are found in the dictionary of type objects.

`PyTypeObject` `PyProperty_Type`

*Part of the [Stable ABI](#).*

The type object for the built-in descriptor types.

`PyObject` \*`PyDescr_NewGetSet(PyTypeObject` \*type, struct `PyGetSetDef` \*getset)

*Return value: New reference. Part of the [Stable ABI](#).*

`PyObject` \*`PyDescr_NewMember(PyTypeObject` \*type, struct `PyMemberDef` \*meth)

*Return value: New reference. Part of the [Stable ABI](#).*

`PyObject` \*`PyDescr_NewMethod(PyTypeObject` \*type, struct `PyMethodDef` \*meth)

*Return value: New reference. Part of the [Stable ABI](#).*

`PyObject` \*`PyDescr_NewWrapper(PyTypeObject` \*type, struct `wrapperbase` \*wrapper, void \*wrapped)

*Return value: New reference.*

`PyObject` \*`PyDescr_NewClassMethod(PyTypeObject` \*type, `PyMethodDef` \*method)

*Return value: New reference. Part of the [Stable ABI](#).*

int `PyDescr_IsData(PyObject` \*descr)

Return non-zero if the descriptor objects *descr* describes a

data attribute, or 0 if it describes a method. *descr* must be a descriptor object; there is no error checking.

`PyObject*` `PyWrapper_New(PyObject*, PyObject*)`

*Return value:* New reference. Part of the [Stable ABI](#).

# Slice Objects

`PyTypeObject` `PySlice_Type`

*Part of the [Stable ABI](#).*

The type object for slice objects. This is the same as `slice` in the Python layer.

`int` `PySlice_Check(PyObject *ob)`

Return true if `ob` is a slice object; `ob` must not be `NULL`. This function always succeeds.

`PyObject *``PySlice_New(PyObject *start, PyObject *stop, PyObject *step)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a new slice object with the given values. The `start`, `stop`, and `step` parameters are used as the values of the slice object attributes of the same names. Any of the values may be `NULL`, in which case the `None` will be used for the corresponding attribute. Return `NULL` if the new object could not be allocated.

`int` `PySlice_GetIndices(PyObject *slice, Py_ssize_t length, Py_ssize_t *start, Py_ssize_t *stop, Py_ssize_t *step)`

*Part of the [Stable ABI](#).*

Retrieve the start, stop and step indices from the slice object `slice`, assuming a sequence of length `length`. Treats indices greater than `length` as errors.

Returns `0` on success and `-1` on error with no exception set (unless one of the indices was not `None` and failed to be converted to an integer, in which case `-1` is returned with an exception set).

You probably do not want to use this function.

*Changed in version 3.2:* The parameter type for the *slice* parameter was `PySliceObject*` before.

```
int PySlice_GetIndicesEx(PyObject *slice, Py_ssize_t length,  
Py_ssize_t *start, Py_ssize_t *stop, Py_ssize_t *step, Py_ssize_t  
*slicelength)
```

Part of the *Stable ABI*.

Usable replacement for `PySlice_GetIndices()`. Retrieve the start, stop, and step indices from the slice object *slice* assuming a sequence of length *length*, and store the length of the slice in *slicelength*. Out of bounds indices are clipped in a manner consistent with the handling of normal slices.

Returns 0 on success and -1 on error with exception set.

### Note

This function is considered not safe for resizable sequences. Its invocation should be replaced by a combination of `PySlice_Unpack()` and `PySlice_AdjustIndices()` where

```
if (PySlice_GetIndicesEx(slice, length, &start, &stop, &step, &slicelength) != 0)  
    // return error  
}
```

is replaced by

```
if (PySlice_Unpack(slice, &start, &stop, &step) < 0)  
    // return error  
}  
slicelength = PySlice_AdjustIndices(length, &start, &stop, &step);
```

*Changed in version 3.2:* The parameter type for the *slice* parameter was `PySliceObject*` before.

*Changed in version 3.6.1:* If `Py_LIMITED_API` is not set or set to the value between `0x03050400` and `0x03060000` (not including) or `0x03060100` or higher `PySlice_GetIndicesEx()` is implemented as a macro

using **PySlice\_Unpack()** and **PySlice\_AdjustIndices()**. Arguments *start*, *stop* and *step* are evaluated more than once.

*Deprecated since version 3.6.1:* If `Py_LIMITED_API` is set to the value less than `0x03050400` or between `0x03060000` and `0x03060100` (not including)

**PySlice\_GetIndicesEx()** is a deprecated function.

```
int PySlice_Unpack(PyObject *slice, Py_ssize_t *start, Py_ssize_t *stop, Py_ssize_t *step)
```

*Part of the [Stable ABI](#) since version 3.7.*

Extract the start, stop and step data members from a slice object as C integers. Silently reduce values larger than `Py_SSIZE_T_MAX` to `Py_SSIZE_T_MAX`, silently boost the start and stop values less than `Py_SSIZE_T_MIN` to `Py_SSIZE_T_MIN`, and silently boost the step values less than `-Py_SSIZE_T_MAX` to `-Py_SSIZE_T_MAX`.

Return `-1` on error, `0` on success.

*New in version 3.6.1.*

```
Py_ssize_t PySlice_AdjustIndices(Py_ssize_t length, Py_ssize_t *start, Py_ssize_t *stop, Py_ssize_t step)
```

*Part of the [Stable ABI](#) since version 3.7.*

Adjust start/end slice indices assuming a sequence of the specified length. Out of bounds indices are clipped in a manner consistent with the handling of normal slices.

Return the length of the slice. Always successful. Doesn't call Python code.

*New in version 3.6.1.*

## Ellipsis Object

```
PyObject *Py_Ellipsis
```

The Python `Ellipsis` object. This object has no methods. Like `Py_None`, it is an `immortal` [<https://peps.python.org/pep-0683/>]. singleton object.

*Changed in version 3.12:* `Py_Ellipsis` is immortal.

# MemoryView objects

A **memoryview** object exposes the C level **buffer interface** as a Python object which can then be passed around like any other object.

**PyObject** \*PyMemoryView\_FromObject(PyObject \*obj)

*Return value:* New reference. Part of the **Stable ABI**.

Create a memoryview object from an object that provides the buffer interface. If *obj* supports writable buffer exports, the memoryview object will be read/write, otherwise it may be either read-only or read/write at the discretion of the exporter.

**PyObject** \*PyMemoryView\_FromMemory(char \*mem, Py\_ssize\_t size, int flags)

*Return value:* New reference. Part of the **Stable ABI** since version 3.7.

Create a memoryview object using *mem* as the underlying buffer. *flags* can be one of **PyBUF\_READ** or **PyBUF\_WRITE**.

*New in version 3.3.*

**PyObject** \*PyMemoryView\_FromBuffer(const **Py\_buffer** \*view)

*Return value:* New reference. Part of the **Stable ABI** since version 3.11.

Create a memoryview object wrapping the given buffer structure *view*. For simple byte buffers,

**PyMemoryView\_FromMemory()** is the preferred function.

**PyObject** \*PyMemoryView\_GetContiguous(PyObject \*obj, int buffertype, char order)

*Return value:* New reference. Part of the **Stable ABI**.

Create a memoryview object to a **contiguous** chunk of

memory (in either 'C' or 'F' or *tran order*) from an object that defines the buffer interface. If memory is contiguous, the `memoryview` object points to the original memory. Otherwise, a copy is made and the `memoryview` points to a new bytes object.

`int PyMemoryView_Check(PyObject *obj)`

Return true if the object *obj* is a `memoryview` object. It is not currently allowed to create subclasses of `memoryview`. This function always succeeds.

`Py_buffer *PyMemoryView_GET_BUFFER(PyObject *mview)`

Return a pointer to the `memoryview`'s private copy of the exporter's buffer. *mview* **must** be a `memoryview` instance; this macro doesn't check its type, you must do it yourself or you will risk crashes.

`PyObject *PyMemoryView_GET_BASE(PyObject *mview)`

Return either a pointer to the exporting object that the `memoryview` is based on or `NULL` if the `memoryview` has been created by one of the functions

`PyMemoryView_FromMemory()` or

`PyMemoryView_FromBuffer()`. *mview* **must** be a `memoryview` instance.

# Weak Reference Objects

Python supports *weak references* as first-class objects. There are two specific object types which directly implement weak references. The first is a simple reference object, and the second acts as a proxy for the original object as much as it can.

`int PyWeakref_Check(PyObject *ob)`

Return true if *ob* is either a reference or proxy object. This function always succeeds.

`int PyWeakref_CheckRef(PyObject *ob)`

Return true if *ob* is a reference object. This function always succeeds.

`int PyWeakref_CheckProxy(PyObject *ob)`

Return true if *ob* is a proxy object. This function always succeeds.

`PyObject *PyWeakref_NewRef(PyObject *ob, PyObject *callback)`

*Return value:* New reference. Part of the [Stable ABI](#).

Return a weak reference object for the object *ob*. This will always return a new reference, but is not guaranteed to create a new object; an existing reference object may be returned. The second parameter, *callback*, can be a callable object that receives notification when *ob* is garbage collected; it should accept a single parameter, which will be the weak reference object itself. *callback* may also be `None` or `NULL`. If *ob* is not a weakly referencable object, or if *callback* is not callable, `None`, or `NULL`, this will return `NULL` and raise [TypeError](#).

`PyObject *PyWeakref_NewProxy(PyObject *ob, PyObject *callback)`

*Return value: New reference. Part of the [Stable ABI](#).*

Return a weak reference proxy object for the object *ob*. This will always return a new reference, but is not guaranteed to create a new object; an existing proxy object may be returned. The second parameter, *callback*, can be a callable object that receives notification when *ob* is garbage collected; it should accept a single parameter, which will be the weak reference object itself. *callback* may also be `None` or `NULL`. If *ob* is not a weakly referencable object, or if *callback* is not callable, `None`, or `NULL`, this will return `NULL` and raise [TypeError](#).

[PyObject](#) \*PyWeakref\_GetObject([PyObject](#) \*ref)

*Return value: Borrowed reference. Part of the [Stable ABI](#).*

Return the referenced object from a weak reference, *ref*. If the referent is no longer live, returns `Py_None`.

### Note

This function returns a [borrowed reference](#) to the referenced object. This means that you should always call [Py\\_INCREF\(\)](#) on the object except when it cannot be destroyed before the last usage of the borrowed reference.

[PyObject](#) \*PyWeakref\_GET\_OBJECT([PyObject](#) \*ref)

*Return value: Borrowed reference.*

Similar to [PyWeakref\\_GetObject\(\)](#), but does no error checking.

void PyObject\_ClearWeakRefs([PyObject](#) \*object)

*Part of the [Stable ABI](#).*

This function is called by the [tp\\_dealloc](#) handler to clear weak references.

This iterates through the weak references for *object* and calls callbacks for those references which have one. It returns when all callbacks have been attempted.

# Capsules

Refer to [Providing a C API for an Extension Module](#) for more information on using these objects.

*New in version 3.1.*

type `PyCapsule`

This subtype of `PyObject` represents an opaque value, useful for C extension modules who need to pass an opaque value (as a `void*` pointer) through Python code to other C code. It is often used to make a C function pointer defined in one module available to other modules, so the regular import mechanism can be used to access C APIs defined in dynamically loaded modules.

type `PyCapsule_Destructor`

*Part of the [Stable ABI](#).*

The type of a destructor callback for a capsule. Defined as:

```
typedef void (*PyCapsule_Destructor) (PyObject *);
```

See `PyCapsule_New()` for the semantics of `PyCapsule_Destructor` callbacks.

int `PyCapsule_CheckExact(PyObject *p)`

Return true if its argument is a `PyCapsule`. This function always succeeds.

`PyObject *``PyCapsule_New(void *pointer, const char *name, PyCapsule_Destructor destructor)`

*Return value: New reference. Part of the [Stable ABI](#).*

Create a `PyCapsule` encapsulating the *pointer*. The *pointer* argument may not be `NULL`.

On failure, set an exception and return `NULL`.

The *name* string may either be `NULL` or a pointer to a valid C string. If non-`NULL`, this string must outlive the capsule. (Though it is permitted to free it inside the *destructor*.)

If the *destructor* argument is not `NULL`, it will be called with the capsule as its argument when it is destroyed.

If this capsule will be stored as an attribute of a module, the *name* should be specified as `modulename.attributename`. This will enable other modules to import the capsule using `PyCapsule_Import()`.

`void *PyCapsule_GetPointer(PyObject *capsule, const char *name)`

*Part of the [Stable ABI](#).*

Retrieve the *pointer* stored in the capsule. On failure, set an exception and return `NULL`.

The *name* parameter must compare exactly to the name stored in the capsule. If the name stored in the capsule is `NULL`, the *name* passed in must also be `NULL`. Python uses the C function `strcmp()` to compare capsule names.

`PyCapsule_Destructor PyCapsule_GetDestructor(PyObject *capsule)`

*Part of the [Stable ABI](#).*

Return the current destructor stored in the capsule. On failure, set an exception and return `NULL`.

It is legal for a capsule to have a `NULL` destructor. This makes a `NULL` return code somewhat ambiguous; use `PyCapsule_IsValid()` or `PyErr_Occurred()` to disambiguate.

`void *PyCapsule_GetContext(PyObject *capsule)`

*Part of the [Stable ABI](#).*

Return the current context stored in the capsule. On failure, set an exception and return `NULL`.

It is legal for a capsule to have a `NULL` context. This makes a `NULL` return code somewhat ambiguous; use `PyCapsule_IsValid()` or `PyErr_Occurred()` to disambiguate.

`const char *PyCapsule_GetName(PyObject *capsule)`

*Part of the [Stable ABI](#).*

Return the current name stored in the capsule. On failure, set an exception and return `NULL`.

It is legal for a capsule to have a `NULL` name. This makes a `NULL` return code somewhat ambiguous; use `PyCapsule_IsValid()` or `PyErr_Occurred()` to disambiguate.

`void *PyCapsule_Import(const char *name, int no_block)`

*Part of the [Stable ABI](#).*

Import a pointer to a C object from a capsule attribute in a module. The *name* parameter should specify the full name to the attribute, as in `module.attribute`. The *name* stored in the capsule must match this string exactly.

Return the capsule's internal *pointer* on success. On failure, set an exception and return `NULL`.

*Changed in version 3.3: `no_block` has no effect anymore.*

`int PyCapsule_IsValid(PyObject *capsule, const char *name)`

*Part of the [Stable ABI](#).*

Determines whether or not *capsule* is a valid capsule. A valid capsule is non-`NULL`, passes `PyCapsule_CheckExact()`, has a non-`NULL` pointer stored in it, and its internal name matches the *name* parameter. (See `PyCapsule_GetPointer()` for information on how capsule names are compared.)

In other words, if `PyCapsule_IsValid()` returns a true value, calls to any of the accessors (any function starting with `PyCapsule_Get`) are guaranteed to succeed.

Return a nonzero value if the object is valid and matches the name passed in. Return 0 otherwise. This function will not fail.

int PyCapsule\_SetContext(PyObject \*capsule, void \*context)

*Part of the [Stable ABI](#).*

Set the context pointer inside *capsule* to *context*.

Return 0 on success. Return nonzero and set an exception on failure.

int PyCapsule\_SetDestructor(PyObject \*capsule,  
[PyCapsule\\_Destructor](#) destructor)

*Part of the [Stable ABI](#).*

Set the destructor inside *capsule* to *destructor*.

Return 0 on success. Return nonzero and set an exception on failure.

int PyCapsule\_SetName(PyObject \*capsule, const char \*name)

*Part of the [Stable ABI](#).*

Set the name inside *capsule* to *name*. If non-NULL, the name must outlive the capsule. If the previous *name* stored in the capsule was not NULL, no attempt is made to free it.

Return 0 on success. Return nonzero and set an exception on failure.

int PyCapsule\_SetPointer(PyObject \*capsule, void \*pointer)

*Part of the [Stable ABI](#).*

Set the void pointer inside *capsule* to *pointer*. The pointer may not be NULL.

Return 0 on success. Return nonzero and set an exception on failure.

# Frame Objects

type PyFrameObject

*Part of the [Limited API](#) (as an opaque struct).*

The C structure of the objects used to describe frame objects.

There are no public members in this structure.

*Changed in version 3.11:* The members of this structure were removed from the public C API. Refer to the [What's New entry](#) for details.

The [PyEval\\_GetFrame\(\)](#) and [PyThreadState\\_GetFrame\(\)](#) functions can be used to get a frame object.

See also [Reflection](#).

[PyTypeObject](#) PyFrame\_Type

The type of frame objects. It is the same object as [types.FrameType](#) in the Python layer.

*Changed in version 3.11:* Previously, this type was only available after including `<frameobject.h>`.

int PyFrame\_Check([PyObject](#) \*obj)

Return non-zero if *obj* is a frame object.

*Changed in version 3.11:* Previously, this function was only available after including `<frameobject.h>`.

[PyFrameObject](#) \*PyFrame\_GetBack([PyFrameObject](#) \*frame)

Get the *frame* next outer frame.

Return a [strong reference](#), or `NULL` if *frame* has no outer frame.

*New in version 3.9.*

**PyObject \***PyFrame\_GetBuiltins(**PyFrameObject \***frame)

Get the *frame*'s `f_builtins` attribute.

Return a [strong reference](#). The result cannot be `NULL`.

*New in version 3.11.*

**PyCodeObject \***PyFrame\_GetCode(**PyFrameObject \***frame)

Part of the [Stable ABI](#) since version 3.10.

Get the *frame* code.

Return a [strong reference](#).

The result (frame code) cannot be `NULL`.

*New in version 3.9.*

**PyObject \***PyFrame\_GetGenerator(**PyFrameObject \***frame)

Get the generator, coroutine, or async generator that owns this frame, or `NULL` if this frame is not owned by a generator. Does not raise an exception, even if the return value is `NULL`.

Return a [strong reference](#), or `NULL`.

*New in version 3.11.*

**PyObject \***PyFrame\_GetGlobals(**PyFrameObject \***frame)

Get the *frame*'s `f_globals` attribute.

Return a [strong reference](#). The result cannot be `NULL`.

*New in version 3.11.*

**int** PyFrame\_GetLasti(**PyFrameObject \***frame)

Get the *frame*'s `f_lasti` attribute.

Returns -1 if `frame.f_lasti` is `None`.

*New in version 3.11.*

`PyObject *PyFrame_GetVar(PyFrameObject *frame, PyObject *name)`

Get the variable *name* of *frame*.

- Return a [strong reference](#) to the variable value on success.
- Raise `NameError` and return `NULL` if the variable does not exist.
- Raise an exception and return `NULL` on error.

*name* type must be a `str`.

*New in version 3.12.*

`PyObject *PyFrame_GetVarString(PyFrameObject *frame, const char *name)`

Similar to `PyFrame_GetVar()`, but the variable name is a C string encoded in UTF-8.

*New in version 3.12.*

`PyObject *PyFrame_GetLocals(PyFrameObject *frame)`

Get the *frame*'s `f_locals` attribute (`dict`).

Return a [strong reference](#).

*New in version 3.11.*

`int PyFrame_GetLineNumber(PyFrameObject *frame)`

Part of the [Stable ABI](#) since version 3.10.

Return the line number that *frame* is currently executing.

## Internal Frames

Unless using **PEP 523** [<https://peps.python.org/pep-0523/>], you will not need this.

struct `_PyInterpreterFrame`

The interpreter's internal frame representation.

*New in version 3.11.*

`PyObject *``PyUnstable_InterpreterFrame_GetCode(struct`  
`_PyInterpreterFrame *frame);`

*This is **Unstable API**. It may change without warning in minor releases.*

Return a **strong reference** to the code object for the frame.

*New in version 3.12.*

`int` `PyUnstable_InterpreterFrame_GetLasti(struct`  
`_PyInterpreterFrame *frame);`

*This is **Unstable API**. It may change without warning in minor releases.*

Return the byte offset into the last executed instruction.

*New in version 3.12.*

`int` `PyUnstable_InterpreterFrame_GetLine(struct`  
`_PyInterpreterFrame *frame);`

*This is **Unstable API**. It may change without warning in minor releases.*

Return the currently executing line number, or -1 if there is

no line number.

*New in version 3.12.*

# Generator Objects

Generator objects are what Python uses to implement generator iterators. They are normally created by iterating over a function that yields values, rather than explicitly calling `PyGen_New()` or `PyGen_NewWithQualName()`.

type PyGenObject

The C structure used for generator objects.

PyTypeObject PyGen\_Type

The type object corresponding to generator objects.

int PyGen\_Check(PyObject \*ob)

Return true if *ob* is a generator object; *ob* must not be NULL. This function always succeeds.

int PyGen\_CheckExact(PyObject \*ob)

Return true if *ob*'s type is `PyGen_Type`; *ob* must not be NULL. This function always succeeds.

PyObject \*PyGen\_New(PyFrameObject \*frame)

*Return value:* New reference.

Create and return a new generator object based on the *frame* object. A reference to *frame* is stolen by this function. The argument must not be NULL.

PyObject \*PyGen\_NewWithQualName(PyFrameObject \*frame,  
PyObject \*name, PyObject \*qualname)

*Return value:* New reference.

Create and return a new generator object based on the *frame* object, with `__name__` and `__qualname__` set to *name* and *qualname*. A reference to *frame* is stolen by this function. The

*frame* argument must not be NULL.

# Coroutine Objects

*New in version 3.5.*

Coroutine objects are what functions declared with an `async` keyword return.

`type PyCoroObject`

The C structure used for coroutine objects.

`PyTypeObject PyCoro_Type`

The type object corresponding to coroutine objects.

`int PyCoro_CheckExact(PyObject *ob)`

Return true if *ob*'s type is `PyCoro_Type`; *ob* must not be NULL. This function always succeeds.

`PyObject *PyCoro_New(PyFrameObject *frame, PyObject *name, PyObject *qualname)`

*Return value:* New reference.

Create and return a new coroutine object based on the *frame* object, with `__name__` and `__qualname__` set to *name* and *qualname*. A reference to *frame* is stolen by this function. The *frame* argument must not be NULL.

# Context Variables Objects

*Changed in version 3.7.1:*

## Note

In Python 3.7.1 the signatures of all context variables C APIs were **changed** to use `PyObject` pointers instead of `PyContext`, `PyContextVar`, and `PyContextToken`, e.g.:

```
// in 3.7.0:
PyContext *PyContext_New(void);
```

```
// in 3.7.1+:
PyObject *PyContext_New(void);
```

See [bpo-34762](https://bugs.python.org/issue?@action=redirect&bpo=34762) [<https://bugs.python.org/issue?@action=redirect&bpo=34762>] for more details.

*New in version 3.7.*

This section details the public C API for the `contextvars` module.

type `PyContext`

The C structure used to represent a `contextvars.Context` object.

type `PyContextVar`

The C structure used to represent a `contextvars.ContextVar` object.

type `PyContextToken`

The C structure used to represent a `contextvars.Token` object.

**PyObject** PyContext\_Type

The type object representing the *context* type.

**PyObject** PyContextVar\_Type

The type object representing the *context variable* type.

**PyObject** PyContextToken\_Type

The type object representing the *context variable token* type.

Type-check macros:

int PyContext\_CheckExact(PyObject \*o)

Return true if *o* is of type **PyContext\_Type**. *o* must not be NULL. This function always succeeds.

int PyContextVar\_CheckExact(PyObject \*o)

Return true if *o* is of type **PyContextVar\_Type**. *o* must not be NULL. This function always succeeds.

int PyContextToken\_CheckExact(PyObject \*o)

Return true if *o* is of type **PyContextToken\_Type**. *o* must not be NULL. This function always succeeds.

Context object management functions:

**PyObject** \*PyContext\_New(void)

*Return value:* New reference.

Create a new empty context object. Returns NULL if an error has occurred.

**PyObject** \*PyContext\_Copy(PyObject \*ctx)

*Return value:* New reference.

Create a shallow copy of the passed *ctx* context object. Returns NULL if an error has occurred.

**PyObject** \*PyContext\_CopyCurrent(void)

*Return value: New reference.*

Create a shallow copy of the current thread context. Returns `NULL` if an error has occurred.

`int PyContext_Enter(PyObject *ctx)`

Set `ctx` as the current context for the current thread. Returns `0` on success, and `-1` on error.

`int PyContext_Exit(PyObject *ctx)`

Deactivate the `ctx` context and restore the previous context as the current context for the current thread. Returns `0` on success, and `-1` on error.

Context variable functions:

`PyObject *PyContextVar_New(const char *name, PyObject *def)`

*Return value: New reference.*

Create a new `ContextVar` object. The *name* parameter is used for introspection and debug purposes. The *def* parameter specifies a default value for the context variable, or `NULL` for no default. If an error has occurred, this function returns `NULL`.

`int PyContextVar_Get(PyObject *var, PyObject *default_value, PyObject **value)`

Get the value of a context variable. Returns `-1` if an error has occurred during lookup, and `0` if no error occurred, whether or not a value was found.

If the context variable was found, *value* will be a pointer to it. If the context variable was *not* found, *value* will point to:

- *default value*, if not `NULL`;
- the default value of *var*, if not `NULL`;
- `NULL`

Except for `NULL`, the function returns a new reference.

`PyObject *PyContextVar_Set(PyObject *var, PyObject *value)`

*Return value: New reference.*

Set the value of *var* to *value* in the current context. Returns a new token object for this change, or `NULL` if an error has occurred.

`int PyContextVar_Reset(PyObject *var, PyObject *token)`

Reset the state of the *var* context variable to that it was in before `PyContextVar_Set ()` that returned the *token* was called. This function returns `0` on success and `-1` on error.

# DateTime Objects

Various date and time objects are supplied by the `datetime` module. Before using any of these functions, the header file `datetime.h` must be included in your source (note that this is not included by `Python.h`), and the macro `PyDateTime_IMPORT` must be invoked, usually as part of the module initialisation function. The macro puts a pointer to a C structure into a static variable, `PyDateTimeAPI`, that is used by the following macros.

type `PyDateTime_Date`

This subtype of `PyObject` represents a Python date object.

type `PyDateTime_DateTime`

This subtype of `PyObject` represents a Python datetime object.

type `PyDateTime_Time`

This subtype of `PyObject` represents a Python time object.

type `PyDateTime_Delta`

This subtype of `PyObject` represents the difference between two datetime values.

`PyTypeObject` `PyDateTime_DateType`

This instance of `PyTypeObject` represents the Python date type; it is the same object as `datetime.date` in the Python layer.

`PyTypeObject` `PyDateTime_DateTimeType`

This instance of `PyTypeObject` represents the Python datetime type; it is the same object as `datetime.datetime` in the Python layer.

### **PyObject** PyDateTime\_TimeType

This instance of **PyObject** represents the Python time type; it is the same object as **datetime.time** in the Python layer.

### **PyObject** PyDateTime\_DeltaType

This instance of **PyObject** represents Python type for the difference between two datetime values; it is the same object as **datetime.timedelta** in the Python layer.

### **PyObject** PyDateTime\_TZInfoType

This instance of **PyObject** represents the Python time zone info type; it is the same object as **datetime.tzinfo** in the Python layer.

Macro for access to the UTC singleton:

### **PyObject** \*PyDateTime\_TimeZone\_UTC

Returns the time zone singleton representing UTC, the same object as **datetime.timezone.utc**.

*New in version 3.7.*

Type-check macros:

### **int** PyDate\_Check(**PyObject** \*ob)

Return true if *ob* is of type **PyDateTime\_DateType** or a subtype of **PyDateTime\_DateType**. *ob* must not be `NULL`. This function always succeeds.

### **int** PyDate\_CheckExact(**PyObject** \*ob)

Return true if *ob* is of type **PyDateTime\_DateType**. *ob* must not be `NULL`. This function always succeeds.

### **int** PyDateTime\_Check(**PyObject** \*ob)

Return true if *ob* is of type **PyDateTime\_DateTimeType** or a subtype of **PyDateTime\_DateTimeType**. *ob* must not be

NULL. This function always succeeds.

`int PyDateTime_CheckExact(PyObject *ob)`

Return true if *ob* is of type `PyDateTime_DateTimeType`. *ob* must not be NULL. This function always succeeds.

`int PyTime_Check(PyObject *ob)`

Return true if *ob* is of type `PyDateTime_TimeType` or a subtype of `PyDateTime_TimeType`. *ob* must not be NULL. This function always succeeds.

`int PyTime_CheckExact(PyObject *ob)`

Return true if *ob* is of type `PyDateTime_TimeType`. *ob* must not be NULL. This function always succeeds.

`int PyDelta_Check(PyObject *ob)`

Return true if *ob* is of type `PyDateTime_DeltaType` or a subtype of `PyDateTime_DeltaType`. *ob* must not be NULL. This function always succeeds.

`int PyDelta_CheckExact(PyObject *ob)`

Return true if *ob* is of type `PyDateTime_DeltaType`. *ob* must not be NULL. This function always succeeds.

`int PyTZInfo_Check(PyObject *ob)`

Return true if *ob* is of type `PyDateTime_TZInfoType` or a subtype of `PyDateTime_TZInfoType`. *ob* must not be NULL. This function always succeeds.

`int PyTZInfo_CheckExact(PyObject *ob)`

Return true if *ob* is of type `PyDateTime_TZInfoType`. *ob* must not be NULL. This function always succeeds.

Macros to create objects:

`PyObject *PyDate_FromDate(int year, int month, int day)`

*Return value: New reference.*

Return a `datetime.date` object with the specified year, month and day.

**PyObject** \*PyDateTime\_FromDateAndTime(int year, int month, int day, int hour, int minute, int second, int usecond)

*Return value: New reference.*

Return a `datetime.datetime` object with the specified year, month, day, hour, minute, second and microsecond.

**PyObject** \*PyDateTime\_FromDateAndTimeAndFold(int year, int month, int day, int hour, int minute, int second, int usecond, int fold)

*Return value: New reference.*

Return a `datetime.datetime` object with the specified year, month, day, hour, minute, second, microsecond and fold.

*New in version 3.6.*

**PyObject** \*PyTime\_FromTime(int hour, int minute, int second, int usecond)

*Return value: New reference.*

Return a `datetime.time` object with the specified hour, minute, second and microsecond.

**PyObject** \*PyTime\_FromTimeAndFold(int hour, int minute, int second, int usecond, int fold)

*Return value: New reference.*

Return a `datetime.time` object with the specified hour, minute, second, microsecond and fold.

*New in version 3.6.*

**PyObject** \*PyDelta\_FromDSU(int days, int seconds, int useconds)

*Return value: New reference.*

Return a `datetime.timedelta` object representing the

given number of days, seconds and microseconds. Normalization is performed so that the resulting number of microseconds and seconds lie in the ranges documented for `datetime.timedelta` objects.

`PyObject *PyTimeZone_FromOffset(PyObject *offset)`

*Return value:* New reference.

Return a `datetime.timezone` object with an unnamed fixed offset represented by the *offset* argument.

*New in version 3.7.*

`PyObject *PyTimeZone_FromOffsetAndName(PyObject *offset, PyObject *name)`

*Return value:* New reference.

Return a `datetime.timezone` object with a fixed offset represented by the *offset* argument and with tzname *name*.

*New in version 3.7.*

Macros to extract fields from date objects. The argument must be an instance of `PyDateTime_Date`, including subclasses (such as `PyDateTime_DateTime`). The argument must not be `NULL`, and the type is not checked:

`int PyDateTime_GET_YEAR(PyDateTime_Date *o)`

Return the year, as a positive int.

`int PyDateTime_GET_MONTH(PyDateTime_Date *o)`

Return the month, as an int from 1 through 12.

`int PyDateTime_GET_DAY(PyDateTime_Date *o)`

Return the day, as an int from 1 through 31.

Macros to extract fields from datetime objects. The argument must be an instance of `PyDateTime_DateTime`, including subclasses. The argument must not be `NULL`, and the type is not checked:

`int PyDateTime_DATE_GET_HOUR(PyDateTime_DateTime *o)`

Return the hour, as an int from 0 through 23.

`int PyDateTime_DATE_GET_MINUTE(PyDateTime_DateTime *o)`

Return the minute, as an int from 0 through 59.

`int PyDateTime_DATE_GET_SECOND(PyDateTime_DateTime *o)`

Return the second, as an int from 0 through 59.

`int PyDateTime_DATE_GET_MICROSECOND(PyDateTime_DateTime *o)`

Return the microsecond, as an int from 0 through 999999.

`int PyDateTime_DATE_GET_FOLD(PyDateTime_DateTime *o)`

Return the fold, as an int from 0 through 1.

*New in version 3.6.*

`PyObject *PyDateTime_DATE_GET_TZINFO(PyDateTime_DateTime *o)`

Return the tzinfo (which may be `None`).

*New in version 3.10.*

Macros to extract fields from time objects. The argument must be an instance of `PyDateTime_Time`, including subclasses. The argument must not be `NULL`, and the type is not checked:

`int PyDateTime_TIME_GET_HOUR(PyDateTime_Time *o)`

Return the hour, as an int from 0 through 23.

`int PyDateTime_TIME_GET_MINUTE(PyDateTime_Time *o)`

Return the minute, as an int from 0 through 59.

`int PyDateTime_TIME_GET_SECOND(PyDateTime_Time *o)`

Return the second, as an int from 0 through 59.

int PyDateTime\_TIME\_GET\_MICROSECOND(PyDateTime\_Time \*o)

Return the microsecond, as an int from 0 through 999999.

int PyDateTime\_TIME\_GET\_FOLD(PyDateTime\_Time \*o)

Return the fold, as an int from 0 through 1.

*New in version 3.6.*

PyObject \*PyDateTime\_TIME\_GET\_TZINFO(PyDateTime\_Time \*o)

Return the tzinfo (which may be None).

*New in version 3.10.*

Macros to extract fields from time delta objects. The argument must be an instance of **PyDateTime\_Delta**, including subclasses. The argument must not be NULL, and the type is not checked:

int PyDateTime\_DELTA\_GET\_DAYS(PyDateTime\_Delta \*o)

Return the number of days, as an int from -999999999 to 999999999.

*New in version 3.3.*

int PyDateTime\_DELTA\_GET\_SECONDS(PyDateTime\_Delta \*o)

Return the number of seconds, as an int from 0 through 86399.

*New in version 3.3.*

int PyDateTime\_DELTA\_GET\_MICROSECONDS(PyDateTime\_Delta \*o)

Return the number of microseconds, as an int from 0 through 999999.

*New in version 3.3.*

Macros for the convenience of modules implementing the DB API:

`PyObject *PyDateTime_FromTimestamp(PyObject *args)`

*Return value: New reference.*

Create and return a new `datetime.datetime` object given an argument tuple suitable for passing to `datetime.datetime.fromtimestamp()`.

`PyObject *PyDate_FromTimestamp(PyObject *args)`

*Return value: New reference.*

Create and return a new `datetime.date` object given an argument tuple suitable for passing to `datetime.date.fromtimestamp()`.

# Objects for Type Hinting

Various built-in types for type hinting are provided. Currently, two types exist – [GenericAlias](#) and [Union](#). Only `GenericAlias` is exposed to C.

[PyObject](#) \*Py\_GenericAlias([PyObject](#) \*origin, [PyObject](#) \*args)

*Part of the [Stable ABI](#) since version 3.9.*

Create a [GenericAlias](#) object. Equivalent to calling the Python class `types.GenericAlias`. The *origin* and *args* arguments set the `GenericAlias`'s `__origin__` and `__args__` attributes respectively. *origin* should be a [PyTypeObject](#)\*, and *args* can be a [PyTupleObject](#)\* or any `PyObject*`. If *args* passed is not a tuple, a 1-tuple is automatically constructed and `__args__` is set to `(args,)`. Minimal checking is done for the arguments, so the function will succeed even if *origin* is not a type. The `GenericAlias`'s `__parameters__` attribute is constructed lazily from `__args__`. On failure, an exception is raised and `NULL` is returned.

Here's an example of how to make an extension type generic:

```
...
static PyMethodDef my_obj_methods[] = {
    // Other methods.
    ...
    {"__class_getitem__", Py_GenericAlias, METH_O|METH_NOARGS, 0},
    ...
}
```

## See also

The data model method `__class_getitem__()`.

*New in version 3.9.*

**PyTypeObject** `Py_GenericAliasType`

*Part of the [Stable ABI](#) since version 3.9.*

The C type of the object returned by `Py_GenericAlias()`.  
Equivalent to `types.GenericAlias` in Python.

*New in version 3.9.*

# Initialization, Finalization, and Threads

See also [Python Initialization Configuration](#).

## Before Python Initialization

In an application embedding Python, the `Py_Initialize()` function must be called before using any other Python/C API functions; with the exception of a few functions and the [global configuration variables](#).

The following functions can be safely called before Python is initialized:

- Configuration functions:
  - `PyImport_AppendInittab()`
  - `PyImport_ExtendInittab()`
  - `PyInitFrozenExtensions()`
  - `PyMem_SetAllocator()`
  - `PyMem_SetupDebugHooks()`
  - `PyObject_SetArenaAllocator()`
  - `Py_SetPath()`
  - `Py_SetProgramName()`
  - `Py_SetPythonHome()`
  - `Py_SetStandardStreamEncoding()`
  - `PySys_AddWarnOption()`
  - `PySys_AddXOption()`
  - `PySys_ResetWarnOptions()`
- Informative functions:
  - `Py_IsInitialized()`
  - `PyMem_GetAllocator()`
  - `PyObject_GetArenaAllocator()`
  - `Py_GetBuildInfo()`
  - `Py_GetCompiler()`

- `Py_GetCopyright()`
- `Py_GetPlatform()`
- `Py_GetVersion()`
- Utilities:
  - `Py_DecodeLocale()`
- Memory allocators:
  - `PyMem_RawMalloc()`
  - `PyMem_RawRealloc()`
  - `PyMem_RawCalloc()`
  - `PyMem_RawFree()`

## Note

The following functions **should not be called** before

`Py_Initialize()`: `Py_EncodeLocale()`, `Py_GetPath()`,  
`Py_GetPrefix()`, `Py_GetExecPrefix()`,  
`Py_GetProgramFullPath()`, `Py_GetPythonHome()`,  
`Py_GetProgramName()` and `PyEval_InitThreads()`.

## Global configuration variables

Python has variables for the global configuration to control different features and options. By default, these flags are controlled by [command line options](#).

When a flag is set by an option, the value of the flag is the number of times that the option was set. For example, `-b` sets

`Py_BytesWarningFlag` to 1 and `-bb` sets  
`Py_BytesWarningFlag` to 2.

`int Py_BytesWarningFlag`

This API is kept for backward compatibility: setting `PyConfig.bytes_warning` should be used instead, see [Python Initialization Configuration](#).

Issue a warning when comparing `bytes` or `bytearray` with `str` or `bytes` with `int`. Issue an error if greater or equal to 2.

Set by the **-b** option.

*Deprecated since version 3.12.*

int Py\_DebugFlag

This API is kept for backward compatibility: setting **PyConfig.parser\_debug** should be used instead, see [Python Initialization Configuration](#).

Turn on parser debugging output (for expert only, depending on compilation options).

Set by the **-d** option and the **PYTHONDEBUG** environment variable.

*Deprecated since version 3.12.*

int Py\_DontWriteBytecodeFlag

This API is kept for backward compatibility: setting **PyConfig.write\_bytecode** should be used instead, see [Python Initialization Configuration](#).

If set to non-zero, Python won't try to write `.pyc` files on the import of source modules.

Set by the **-B** option and the **PYTHONDONTWRITEBYTECODE** environment variable.

*Deprecated since version 3.12.*

int Py\_FrozenFlag

This API is kept for backward compatibility: setting **PyConfig.pathconfig\_warnings** should be used instead, see [Python Initialization Configuration](#).

Suppress error messages when calculating the module search path in **Py\_GetPath()**.

Private flag used by `_freeze_module` and `frozenmain` programs.

*Deprecated since version 3.12.*

int Py\_HashRandomizationFlag

This API is kept for backward compatibility: setting `PyConfig.hash_seed` and `PyConfig.use_hash_seed` should be used instead, see [Python Initialization Configuration](#).

Set to 1 if the `PYTHONHASHSEED` environment variable is set to a non-empty string.

If the flag is non-zero, read the `PYTHONHASHSEED` environment variable to initialize the secret hash seed.

*Deprecated since version 3.12.*

int Py\_IgnoreEnvironmentFlag

This API is kept for backward compatibility: setting `PyConfig.use_environment` should be used instead, see [Python Initialization Configuration](#).

Ignore all `PYTHON*` environment variables, e.g. `PYTHONPATH` and `PYTHONHOME`, that might be set.

Set by the `-E` and `-I` options.

*Deprecated since version 3.12.*

int Py\_InspectFlag

This API is kept for backward compatibility: setting `PyConfig.inspect` should be used instead, see [Python Initialization Configuration](#).

When a script is passed as first argument or the `-c` option is used, enter interactive mode after executing the script or the command, even when `sys.stdin` does not appear to be a terminal.

Set by the `-i` option and the `PYTHONINSPECT` environment variable.

*Deprecated since version 3.12.*

int `Py_InteractiveFlag`

This API is kept for backward compatibility: setting `PyConfig.interactive` should be used instead, see [Python Initialization Configuration](#).

Set by the `-i` option.

*Deprecated since version 3.12.*

int `Py_IsolatedFlag`

This API is kept for backward compatibility: setting `PyConfig.isolated` should be used instead, see [Python Initialization Configuration](#).

Run Python in isolated mode. In isolated mode `sys.path` contains neither the script's directory nor the user's site-packages directory.

Set by the `-I` option.

*New in version 3.4.*

*Deprecated since version 3.12.*

int `Py_LegacyWindowsFSEncodingFlag`

This API is kept for backward compatibility: setting `PyPreConfig.legacy_windows_fs_encoding` should be used instead, see [Python Initialization Configuration](#).

If the flag is non-zero, use the `mbcs` encoding with `replace` error handler, instead of the UTF-8 encoding with `surrogatepass` error handler, for the [filesystem encoding and error handler](#).

Set to `1` if the `PYTHONLEGACYWINDOWSFSENCODING` environment variable is set to a non-empty string.

See [PEP 529](#) [<https://peps.python.org/pep-0529/>] for more details.

**Availability:** Windows.

*Deprecated since version 3.12.*

`int Py_LegacyWindowsStdioFlag`

This API is kept for backward compatibility: setting `PyConfig.legacy_windows_stdio` should be used instead, see [Python Initialization Configuration](#).

If the flag is non-zero, use `io.FileIO` instead of `io._WindowsConsoleIO` for `sys` standard streams.

Set to 1 if the `PYTHONLEGACYWINDOWSSTDIO` environment variable is set to a non-empty string.

See [PEP 528](#) [<https://peps.python.org/pep-0528/>] for more details.

**Availability:** Windows.

*Deprecated since version 3.12.*

`int Py_NoSiteFlag`

This API is kept for backward compatibility: setting `PyConfig.site_import` should be used instead, see [Python Initialization Configuration](#).

Disable the import of the module `site` and the site-dependent manipulations of `sys.path` that it entails. Also disable these manipulations if `site` is explicitly imported later (call `site.main()` if you want them to be triggered).

Set by the `-S` option.

*Deprecated since version 3.12.*

`int Py_NoUserSiteDirectory`

This API is kept for backward compatibility: setting `PyConfig.user_site_directory` should be used instead, see [Python Initialization Configuration](#).

Don't add the `user site-packages directory` to

**sys.path.**

Set by the **-s** and **-I** options, and the **PYTHONNOUSERSITE** environment variable.

*Deprecated since version 3.12.*

int Py\_OptimizeFlag

This API is kept for backward compatibility: setting **PyConfig.optimization\_level** should be used instead, see [Python Initialization Configuration](#).

Set by the **-O** option and the **PYTHONOPTIMIZE** environment variable.

*Deprecated since version 3.12.*

int Py\_QuietFlag

This API is kept for backward compatibility: setting **PyConfig.quiet** should be used instead, see [Python Initialization Configuration](#).

Don't display the copyright and version messages even in interactive mode.

Set by the **-q** option.

*New in version 3.2.*

*Deprecated since version 3.12.*

int Py\_UnbufferedStdioFlag

This API is kept for backward compatibility: setting **PyConfig.buffered\_stdio** should be used instead, see [Python Initialization Configuration](#).

Force the stdout and stderr streams to be unbuffered.

Set by the **-u** option and the **PYTHONUNBUFFERED** environment variable.

*Deprecated since version 3.12.*

int Py\_VerboseFlag

This API is kept for backward compatibility: setting **PyConfig.verbose** should be used instead, see [Python Initialization Configuration](#).

Print a message each time a module is initialized, showing the place (filename or built-in module) from which it is loaded. If greater or equal to 2, print a message for each file that is checked for when searching for a module. Also provides information on module cleanup at exit.

Set by the **-v** option and the **PYTHONVERBOSE** environment variable.

*Deprecated since version 3.12.*

## Initializing and finalizing the interpreter

void Py\_Initialize()

Part of the [Stable ABI](#).

Initialize the Python interpreter. In an application embedding Python, this should be called before using any other Python/C API functions; see [Before Python Initialization](#) for the few exceptions.

This initializes the table of loaded modules (`sys.modules`), and creates the fundamental modules **builtins**, **\_\_main\_\_** and **sys**. It also initializes the module search path (`sys.path`). It does not set `sys.argv`; use **PySys\_SetArgvEx()** for that. This is a no-op when called for a second time (without calling **Py\_FinalizeEx()** first). There is no return value; it is a fatal error if the initialization fails.

Use the **Py\_InitializeFromConfig()** function to customize the [Python Initialization Configuration](#).

## Note

On Windows, changes the console mode from `O_TEXT` to `O_BINARY`, which will also affect non-Python uses of the console using the C Runtime.

`void Py_InitializeEx(int initsigs)`

*Part of the [Stable ABI](#).*

This function works like `Py_Initialize()` if *initsigs* is 1. If *initsigs* is 0, it skips initialization registration of signal handlers, which might be useful when Python is embedded.

Use the `Py_InitializeFromConfig()` function to customize the [Python Initialization Configuration](#).

`int Py_IsInitialized()`

*Part of the [Stable ABI](#).*

Return true (nonzero) when the Python interpreter has been initialized, false (zero) if not. After `Py_FinalizeEx()` is called, this returns false until `Py_Initialize()` is called again.

`int Py_FinalizeEx()`

*Part of the [Stable ABI](#) since version 3.6.*

Undo all initializations made by `Py_Initialize()` and subsequent use of Python/C API functions, and destroy all sub-interpreters (see `Py_NewInterpreter()` below) that were created and not yet destroyed since the last call to `Py_Initialize()`. Ideally, this frees all memory allocated by the Python interpreter. This is a no-op when called for a second time (without calling `Py_Initialize()` again first). Normally the return value is 0. If there were errors during finalization (flushing buffered data), -1 is returned.

This function is provided for a number of reasons. An embedding application might want to restart Python without having to restart the application itself. An application that has loaded the Python interpreter from a dynamically loadable

library (or DLL) might want to free all memory allocated by Python before unloading the DLL. During a hunt for memory leaks in an application a developer might want to free all memory allocated by Python before exiting from the application.

**Bugs and caveats:** The destruction of modules and objects in modules is done in random order; this may cause destructors (`__del__()` methods) to fail when they depend on other objects (even functions) or modules. Dynamically loaded extension modules loaded by Python are not unloaded. Small amounts of memory allocated by the Python interpreter may not be freed (if you find a leak, please report it). Memory tied up in circular references between objects is not freed. Some memory allocated by extension modules may not be freed. Some extensions may not work properly if their initialization routine is called more than once; this can happen if an application calls `Py_Initialize()` and `Py_FinalizeEx()` more than once.

Raises an [auditing event](#)

`cpython._PySys_ClearAuditHooks` with no arguments.

*New in version 3.6.*

`void Py_Finalize()`

*Part of the [Stable ABI](#).*

This is a backwards-compatible version of

`Py_FinalizeEx()` that disregards the return value.

## Process-wide parameters

`int Py_SetStandardStreamEncoding(const char *encoding, const char *errors)`

This API is kept for backward compatibility: setting

`PyConfig.stdio_encoding` and

`PyConfig.stdio_errors` should be used instead, see [Python Initialization Configuration](#).

This function should be called before `Py_Initialize()`, if it is called at all. It specifies which encoding and error handling to use with standard IO, with the same meanings as in `str.encode()`.

It overrides `PYTHONIOENCODING` values, and allows embedding code to control IO encoding when the environment variable does not work.

*encoding* and/or *errors* may be `NULL` to use `PYTHONIOENCODING` and/or default values (depending on other settings).

Note that `sys.stderr` always uses the “backslashreplace” error handler, regardless of this (or any other) setting.

If `Py_FinalizeEx()` is called, this function will need to be called again in order to affect subsequent calls to `Py_Initialize()`.

Returns `0` if successful, a nonzero value on error (e.g. calling after the interpreter has already been initialized).

*New in version 3.4.*

*Deprecated since version 3.11.*

`void Py_SetProgramName(const wchar_t *name)`

*Part of the [Stable ABI](#).*

This API is kept for backward compatibility: setting `PyConfig.program_name` should be used instead, see [Python Initialization Configuration](#).

This function should be called before `Py_Initialize()` is called for the first time, if it is called at all. It tells the interpreter the value of the `argv[0]` argument to the `main()` function of the program (converted to wide characters). This is used by `Py_GetPath()` and some other functions below to find the Python run-time libraries relative to the interpreter executable. The default value is `'python'`. The argument should point to a zero-terminated wide

character string in static storage whose contents will not change for the duration of the program's execution. No code in the Python interpreter will change the contents of this storage.

Use `Py_DecodeLocale()` to decode a bytes string to get a `wchar_t*` string.

*Deprecated since version 3.11.*

`wchar_t *Py_GetProgramName()`

*Part of the [Stable ABI](#).*

Return the program name set with `Py_SetProgramName()`, or the default. The returned string points into static storage; the caller should not modify its value.

This function should not be called before `Py_Initialize()`, otherwise it returns `NULL`.

*Changed in version 3.10:* It now returns `NULL` if called before `Py_Initialize()`.

`wchar_t *Py_GetPrefix()`

*Part of the [Stable ABI](#).*

Return the *prefix* for installed platform-independent files. This is derived through a number of complicated rules from the program name set with `Py_SetProgramName()` and some environment variables; for example, if the program name is `'/usr/local/bin/python'`, the prefix is `'/usr/local'`. The returned string points into static storage; the caller should not modify its value. This corresponds to the **prefix** variable in the top-level `Makefile` and the `--prefix` argument to the **configure** script at build time. The value is available to Python code as `sys.prefix`. It is only useful on Unix. See also the next function.

This function should not be called before `Py_Initialize()`, otherwise it returns `NULL`.

*Changed in version 3.10:* It now returns `NULL` if called before

`Py_Initialize()`.

`wchar_t *Py_GetExecPrefix()`

*Part of the [Stable ABI](#).*

Return the *exec-prefix* for installed platform-dependent files. This is derived through a number of complicated rules from the program name set with `Py_SetProgramName()` and some environment variables; for example, if the program name is  `'/usr/local/bin/python'`, the *exec-prefix* is  `'/usr/local'`. The returned string points into static storage; the caller should not modify its value. This corresponds to the **exec\_prefix** variable in the top-level Makefile and the `--exec-prefix` argument to the **configure** script at build time. The value is available to Python code as `sys.exec_prefix`. It is only useful on Unix.

Background: The *exec-prefix* differs from the *prefix* when platform dependent files (such as executables and shared libraries) are installed in a different directory tree. In a typical installation, platform dependent files may be installed in the  `/usr/local/plat` subtree while platform independent may be installed in  `/usr/local`.

Generally speaking, a platform is a combination of hardware and software families, e.g. Sparc machines running the Solaris 2.x operating system are considered the same platform, but Intel machines running Solaris 2.x are another platform, and Intel machines running Linux are yet another platform. Different major revisions of the same operating system generally also form different platforms. Non-Unix operating systems are a different story; the installation strategies on those systems are so different that the *prefix* and *exec-prefix* are meaningless, and set to the empty string. Note that compiled Python bytecode files are platform independent (but not independent from the Python version by which they were compiled!).

System administrators will know how to configure the **mount** or **automount** programs to share  `/usr/local` between

platforms while having `/usr/local/plat` be a different filesystem for each platform.

This function should not be called before `Py_Initialize()`, otherwise it returns `NULL`.

*Changed in version 3.10:* It now returns `NULL` if called before `Py_Initialize()`.

`wchar_t *Py_GetProgramFullPath()`

*Part of the [Stable ABI](#).*

Return the full program name of the Python executable; this is computed as a side-effect of deriving the default module search path from the program name (set by `Py_SetProgramName()` above). The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.executable`.

This function should not be called before `Py_Initialize()`, otherwise it returns `NULL`.

*Changed in version 3.10:* It now returns `NULL` if called before `Py_Initialize()`.

`wchar_t *Py_GetPath()`

*Part of the [Stable ABI](#).*

Return the default module search path; this is computed from the program name (set by `Py_SetProgramName()` above) and some environment variables. The returned string consists of a series of directory names separated by a platform dependent delimiter character. The delimiter character is `:` on Unix and macOS, `;` on Windows. The returned string points into static storage; the caller should not modify its value. The list `sys.path` is initialized with this value on interpreter startup; it can be (and usually is) modified later to change the search path for loading modules.

This function should not be called before `Py_Initialize()`, otherwise it returns `NULL`.

*Changed in version 3.10:* It now returns `NULL` if called before `Py_Initialize()`.

`void Py_SetPath(const wchar_t*)`

*Part of the [Stable ABI](#) since version 3.7.*

This API is kept for backward compatibility: setting `PyConfig.module_search_paths` and `PyConfig.module_search_paths_set` should be used instead, see [Python Initialization Configuration](#).

Set the default module search path. If this function is called before `Py_Initialize()`, then `Py_GetPath()` won't attempt to compute a default search path but uses the one provided instead. This is useful if Python is embedded by an application that has full knowledge of the location of all modules. The path components should be separated by the platform dependent delimiter character, which is `:` on Unix and macOS, `;` on Windows.

This also causes `sys.executable` to be set to the program full path (see `Py_GetProgramFullPath()`) and for `sys.prefix` and `sys.exec_prefix` to be empty. It is up to the caller to modify these if required after calling `Py_Initialize()`.

Use `Py_DecodeLocale()` to decode a bytes string to get a `wchar_t*` string.

The path argument is copied internally, so the caller may free it after the call completes.

*Changed in version 3.8:* The program full path is now used for `sys.executable`, instead of the program name.

*Deprecated since version 3.11.*

`const char *Py_GetVersion()`

*Part of the [Stable ABI](#).*

Return the version of this Python interpreter. This is a string that looks something like

"3.0a5+ (py3k:63103M, May 12 2008, 00:53:55) \n[GCC

The first word (up to the first space character) is the current Python version; the first characters are the major and minor version separated by a period. The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.version`.

See also the `Py_Version` constant.

const char \*Py\_GetPlatform()

*Part of the [Stable ABI](#).*

Return the platform identifier for the current platform. On Unix, this is formed from the “official” name of the operating system, converted to lower case, followed by the major revision number; e.g., for Solaris 2.x, which is also known as SunOS 5.x, the value is `'sunos5'`. On macOS, it is `'darwin'`. On Windows, it is `'win'`. The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.platform`.

const char \*Py\_GetCopyright()

*Part of the [Stable ABI](#).*

Return the official copyright string for the current Python version, for example

`'Copyright 1991–1995 Stichting Mathematisch Centrum, Amsterdam'`

The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.copyright`.

const char \*Py\_GetCompiler()

*Part of the [Stable ABI](#).*

Return an indication of the compiler used to build the current Python version, in square brackets, for example:

```
"[GCC 2.7.2.2]"
```

The returned string points into static storage; the caller should not modify its value. The value is available to Python code as part of the variable `sys.version`.

```
const char *Py_GetBuildInfo()
```

*Part of the [Stable ABI](#).*

Return information about the sequence number and build date and time of the current Python interpreter instance, for example

```
"#67, Aug 1 1997, 22:34:28"
```

The returned string points into static storage; the caller should not modify its value. The value is available to Python code as part of the variable `sys.version`.

```
void PySys_SetArgvEx(int argc, wchar_t **argv, int updatepath)
```

*Part of the [Stable ABI](#).*

This API is kept for backward compatibility: setting `PyConfig.argv`, `PyConfig.parse_argv` and `PyConfig.safe_path` should be used instead, see [Python Initialization Configuration](#).

Set `sys.argv` based on `argc` and `argv`. These parameters are similar to those passed to the program's `main()` function with the difference that the first entry should refer to the script file to be executed rather than the executable hosting the Python interpreter. If there isn't a script that will be run, the first entry in `argv` can be an empty string. If this function fails to initialize `sys.argv`, a fatal condition is signalled using `Py_FatalError()`.

If `updatepath` is zero, this is all the function does. If `updatepath` is non-zero, the function also modifies `sys.path` according to the following algorithm:

- If the name of an existing script is passed in `argv[0]`, the absolute path of the directory where the script is

located is prepended to `sys.path`.

- Otherwise (that is, if `argc` is 0 or `argv[0]` doesn't point to an existing file name), an empty string is prepended to `sys.path`, which is the same as prepending the current working directory (`"."`).

Use `Py_DecodeLocale()` to decode a bytes string to get a `wchar_t*` string.

See also `PyConfig.orig_argv` and `PyConfig.argv` members of the [Python Initialization Configuration](#).

## Note

It is recommended that applications embedding the Python interpreter for purposes other than executing a single script pass 0 as *updatepath*, and update `sys.path` themselves if desired. See [CVE-2008-5983](https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5983) [https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5983].

On versions before 3.1.3, you can achieve the same effect by manually popping the first `sys.path` element after having called `PySys_SetArgv()`, for example using:

```
PyRun_SimpleString("import sys; sys.path.pop(0)\n"
```

*New in version 3.1.3.*

*Deprecated since version 3.11.*

`void PySys_SetArgv(int argc, wchar_t **argv)`

Part of the [Stable ABI](#).

This API is kept for backward compatibility: setting `PyConfig.argv` and `PyConfig.parse_argv` should be used instead, see [Python Initialization Configuration](#).

This function works like `PySys_SetArgvEx()` with *updatepath* set to 1 unless the **python** interpreter was started with the `-I`.

Use `Py_DecodeLocale()` to decode a bytes string to get a `wchar_*` string.

See also `PyConfig.orig_argv` and `PyConfig.argv` members of the [Python Initialization Configuration](#).

*Changed in version 3.4:* The `updatepath` value depends on `-I`.

*Deprecated since version 3.11.*

`void Py_SetPythonHome(const wchar_t *home)`

*Part of the [Stable ABI](#).*

This API is kept for backward compatibility: setting `PyConfig.home` should be used instead, see [Python Initialization Configuration](#).

Set the default “home” directory, that is, the location of the standard Python libraries. See `PYTHONHOME` for the meaning of the argument string.

The argument should point to a zero-terminated character string in static storage whose contents will not change for the duration of the program’s execution. No code in the Python interpreter will change the contents of this storage.

Use `Py_DecodeLocale()` to decode a bytes string to get a `wchar_*` string.

*Deprecated since version 3.11.*

`wchar_t *Py_GetPythonHome()`

*Part of the [Stable ABI](#).*

Return the default “home”, that is, the value set by a previous call to `Py_SetPythonHome()`, or the value of the `PYTHONHOME` environment variable if it is set.

This function should not be called before `Py_Initialize()`, otherwise it returns `NULL`.

*Changed in version 3.10:* It now returns `NULL` if called before

`Py_Initialize()`.

## Thread State and the Global Interpreter Lock

The Python interpreter is not fully thread-safe. In order to support multi-threaded Python programs, there's a global lock, called the [global interpreter lock](#) or [GIL](#), that must be held by the current thread before it can safely access Python objects. Without the lock, even the simplest operations could cause problems in a multi-threaded program: for example, when two threads simultaneously increment the reference count of the same object, the reference count could end up being incremented only once instead of twice.

Therefore, the rule exists that only the thread that has acquired the [GIL](#) may operate on Python objects or call Python/C API functions. In order to emulate concurrency of execution, the interpreter regularly tries to switch threads (see [sys.setswitchinterval\(\)](#)). The lock is also released around potentially blocking I/O operations like reading or writing a file, so that other Python threads can run in the meantime.

The Python interpreter keeps some thread-specific bookkeeping information inside a data structure called [PyThreadState](#). There's also one global variable pointing to the current [PyThreadState](#): it can be retrieved using [PyThreadState\\_Get\(\)](#).

### Releasing the GIL from extension code

Most extension code manipulating the [GIL](#) has the following simple structure:

```
Save the thread state in a local variable.
Release the global interpreter lock.
... Do some blocking I/O operation ...
Reacquire the global interpreter lock.
Restore the thread state from the local variable.
```

This is so common that a pair of macros exists to simplify it:

```
Py_BEGIN_ALLOW_THREADS
... Do some blocking I/O operation ...
Py_END_ALLOW_THREADS
```

The `Py_BEGIN_ALLOW_THREADS` macro opens a new block and declares a hidden local variable; the `Py_END_ALLOW_THREADS` macro closes the block.

The block above expands to the following code:

```
PyThreadState *_save;

_save = PyEval_SaveThread();
... Do some blocking I/O operation ...
PyEval_RestoreThread(_save);
```

Here is how these functions work: the global interpreter lock is used to protect the pointer to the current thread state. When releasing the lock and saving the thread state, the current thread state pointer must be retrieved before the lock is released (since another thread could immediately acquire the lock and store its own thread state in the global variable). Conversely, when acquiring the lock and restoring the thread state, the lock must be acquired before storing the thread state pointer.

## Note

Calling system I/O functions is the most common use case for releasing the GIL, but it can also be useful before calling long-running computations which don't need access to Python objects, such as compression or cryptographic functions operating over memory buffers. For example, the standard `zlib` and `hashlib` modules release the GIL when compressing or hashing data.

## Non-Python created threads

When threads are created using the dedicated Python APIs (such as the `threading` module), a thread state is automatically associated

to them and the code showed above is therefore correct. However, when threads are created from C (for example by a third-party library with its own thread management), they don't hold the GIL, nor is there a thread state structure for them.

If you need to call Python code from these threads (often this will be part of a callback API provided by the aforementioned third-party library), you must first register these threads with the interpreter by creating a thread state data structure, then acquiring the GIL, and finally storing their thread state pointer, before you can start using the Python/C API. When you are done, you should reset the thread state pointer, release the GIL, and finally free the thread state data structure.

The `PyGILState_Ensure()` and `PyGILState_Release()` functions do all of the above automatically. The typical idiom for calling into Python from a C thread is:

```
PyGILState_STATE gstate;
gstate = PyGILState_Ensure();

/* Perform Python actions here. */
result = CallSomeFunction();
/* evaluate result or handle exception */

/* Release the thread. No Python API allowed beyond this
PyGILState_Release(gstate);
```

Note that the `PyGILState_*` functions assume there is only one global interpreter (created automatically by `Py_Initialize()`). Python supports the creation of additional interpreters (using `Py_NewInterpreter()`), but mixing multiple interpreters and the `PyGILState_*` API is unsupported.

## Cautions about `fork()`

Another important thing to note about threads is their behaviour in the face of the C `fork()` call. On most systems with `fork()`, after a process forks only the thread that issued the fork will exist. This has a concrete impact both on how locks must be handled and

on all stored state in CPython's runtime.

The fact that only the “current” thread remains means any locks held by other threads will never be released. Python solves this for `os.fork()` by acquiring the locks it uses internally before the fork, and releasing them afterwards. In addition, it resets any `Lock Objects` in the child. When extending or embedding Python, there is no way to inform Python of additional (non-Python) locks that need to be acquired before or reset after a fork. OS facilities such as `pthread_atfork()` would need to be used to accomplish the same thing. Additionally, when extending or embedding Python, calling `fork()` directly rather than through `os.fork()` (and returning to or calling into Python) may result in a deadlock by one of Python's internal locks being held by a thread that is defunct after the fork. `PyOS_AfterFork_Child()` tries to reset the necessary locks, but is not always able to.

The fact that all other threads go away also means that CPython's runtime state there must be cleaned up properly, which `os.fork()` does. This means finalizing all other `PyThreadState` objects belonging to the current interpreter and all other `PyInterpreterState` objects. Due to this and the special nature of the “main” interpreter, `fork()` should only be called in that interpreter's “main” thread, where the CPython global runtime was originally initialized. The only exception is if `exec()` will be called immediately after.

## High-level API

These are the most commonly used types and functions when writing C extension code, or when embedding the Python interpreter:

type `PyInterpreterState`

*Part of the `Limited API` (as an opaque struct).*

This data structure represents the state shared by a number of cooperating threads. Threads belonging to the same interpreter share their module administration and a few other internal items. There are no public members in this structure.
